Abstracts

39th Hybrid Annual Meeting of the
European Society of
Human Reproduction and Embryology,
Copenhagen - Denmark, 25-28 June 2023

The abstracts are available on-line to all Human Reproduction/Update/Molecular Human Reproduction subscribers and are also freely available to all visitors to the following website https://academic.oup.com/humrep, and on the ESHRE website: www.eshre.eu

Note to the media: All abstracts are strictly embargoed until the time and date of presentation at the conference.

The opinions or views expressed in this abstracts supplement are those of the authors and do not necessarily reflect the opinions or recommendations of ESHRE. The abstracts have been reviewed by the Congress Scientific Committee and revised accordingly by the authors. The selection of abstracts is based on the scores given by an international panel of peer reviewers.

Dosages, indications and methods of use for products that are referred to in the abstracts by the authors are not necessarily appropriate for clinical use and may reflect the clinical experience of the authors or may be derived from the professional literature of other clinical sources. Because of differences between in-vitro and in-vivo systems and between laboratory animal models and clinical data in humans, in-vitro and animal data may not necessarily correlate with clinical results.

The investigators of these abstracts have stated in their submission letter that prospective studies where patients are involved have institutional Ethics Committee approval and informed patient consent, and that the studies using experimental animals have institutional approval. The Publishers have endeavoured to reproduce faithfully all of the abstracts as accepted by the Conference Organisers but can accept no responsibility for inaccuracies or omissions caused by the late receipt of abstracts.

Study question: How the human embryo builds the blastocyst is crucial to improve ART, as morphology of human embryo is a prime determinant to assess implantation potential.

Summary answer: An evolutionarily conserved increase in cell contractility is required to generate the forces driving the compaction, which is the first morphogenetic event shaping the body.

What is known already: The shaping of the human embryo begins with compaction, during which cells come into close contact and form a tighter structure. ART studies suggest that human embryos fail compaction primarily because of defective adhesion. Based on our current understanding of animal morphogenesis, other morphogenetic engines, such as cell contractility, could be involved in shaping the human embryo. However, the molecular, cellular and physical mechanisms driving human embryo morphogenesis remain uncharacterized.

Study design, size, duration: A total of 54 frozen embryos have been used for this work. The use of human embryos donated for research was allowed by the Agence de la Biomédecine (approval number RE 17-011R) in compliance with the International Society for Stem Cell Research guidelines. Donated embryos were cryopreserved and stored at three different centers in Paris. Embryos were then transferred to the Institut Curie where they were immediately thawed and used for the research project.

Participants/materials, setting, methods: Using micropipette aspiration on human embryos, we mapped cell surface tensions during compaction. Drug inhibition and immunostaining of cell contractility and cell-cell adhesion in human embryos reveal what drives the surface tension responsible for compaction. To evaluate cell contractility we focused on F-actin and myosin motor proteins, for adhesion we focused on E-cadherin.

Main results and the role of chance: Mapping cell surface tensions during human compaction reveals a 4-fold increase of tension at the cell-medium interface, from 0.62 ± 0.04 to 2.35 ± 0.08 nN/µm (mean ± SEM of 147 measurements on 10 embryos, Student's t test $p < 10^{-5}$), while cell-cell contacts keep a steady tension ~0.6 nN/µm. Therefore, increased tension at the cell-medium interface drives human embryo compaction, which is qualitatively similar to compaction in mouse embryos (from ~0.2 to 0.4 nN/µm). Further comparison between human and mouse reveals qualitatively similar but quantitavely different mechanical strategies, with human embryos being mechanically least efficient. Inhibition of cell contractility and cell-cell adhesion in human embryos reveals that, while both cellular processes are required for compaction, adhesion involvement plays a permissive role. Only contractility controls the surface tension responsible for compaction. Interestingly, cell contractility and cell-cell adhesion exhibit distinct mechanical signatures when faulty. Analyzing the mechanical signature of naturally failing embryos, we find evidence that non-compacting embryos or partially compacting embryos with excluded cells have defective contractility.

Limitations, reasons for caution: Given the need to use embryos donated to research, which are valuable samples, our sample size is small but sufficient to show statistically significant differences. Moreover, these embryos come from infertile patients undergoing ART.

Wider implications of the findings: Excluded cells from compaction could be aneuploid to protect the embryonic tissue from chromosomal abnormalities. Is there a correlation between their mechanical signature and the fact that they may be aneuploid remains an open question.

How physical laws are used to produce the breathtaking diversity of the shapes of life?

O-004 Male and female blastocysts display differences in development such that embryos assigned an identical morphological grade may have differing viability dependent on their sex

M. Kilbee[1], A. Del Canto Cano[1], G. Clark[1,2], C. Coudereau[1], E. Fernandez Marcos[3], D. Babariya[1], D. Wells[1,2]

Study question: Embryo selection methods based upon morphological or morphokinetic evaluation assume that male and female embryos have identical rates of preimplantation development, but is this true?

Summary answer: The distribution of trophectoderm grades differs for male and female blastocysts. Furthermore, male and female embryos of identical grade may have different probabilities of viability.

What is known already: Previous studies have suggested that male and female embryos may have subtle differences in their rates of preimplantation development. However, this possibility remains controversial. Apart from being of scientific interest, the question of whether the sex of an embryo can affect its growth trajectory is of clinical importance. Morphological grading, the primary method used by most IVF clinics when deciding which embryo to prioritise for transfer, assumes that developmental rates are independent of sex. Similarly, morphokinetic strategies for embryo evaluation, using data gathered from time-lapse incubators, are likely to be compromised if male and female embryos have differing developmental behaviour.

Study design, size, duration: 1,241 blastocysts underwent PGT-A and were shown to be euploid. Chromosome analysis also revealed the sex of the embryos, although this was not disclosed to patients. Standard morphological grading was carried out blindly with respect to the sex of the embryo. Information on clinical outcomes following embryo transfer was available for a subset of 336 embryos. Data was evaluated using various statistical methods to reveal any associations between embryo sex, morphology and clinical outcome.

Participants/materials, setting, methods: Embryos included in this study were derived from patients undergoing routine IVF with PGT-A. The only embryos excluded were those derived from patients carrying a monogenic disease mutation or a chromosome rearrangement. Embryos underwent PGT-A at the blastocyst stage on either day-5 or day-6, using a highly validated method. The euploid embryos were divided into male and female groups and blastocyst morphological grades were considered with respect to rates of implantation, miscarriage and ongoing pregnancy/birth.

Main results and the role of chance: The proportion of embryos biopsied on day-5 versus day-6 was identical for males and females (68% day-5 for both). No difference was observed in blastocyst expansion or inner cell mass grading on day-5. However, a highly significant difference was noted in the distribution of trophectoderm grades (A, B, C, D according to the system of Gardner and Schoolcraft, 1999) ($P < 0.0001$). This was characterised by a disproportionate representation of the highest grade amongst male embryos. 21.6% of male blastocysts had trophectoderm graded 'A', compared to 14.9% of females. Interestingly, euploid male embryos with a 'B' grade trophectoderm were associated with significantly higher implantation rates than females of the same morphological grade (82.1% vs. 58.7%; $P = 0.0002$), but the males of this grade also experienced a higher incidence of biochemical losses (16.7% vs. 4.2%; $P = 0.017$). As a group, male embryos do not have greater viability than female embryos, which implies that the greater proportion of high trophectoderm grades amongst these embryos is not an indicator of superior potential. In turn, this suggests that different criteria should be used for grading trophectoderm in males and females.

Limitations, reasons for caution: It may be desirable to introduce parallel morphological grading systems, one for male embryos and another for female. However, this would only be applicable in cycles involving PGT-A. The observation that embryos of equal grade can have different outcomes depending on their sex should be confirmed in a prospective study.

Wider implications of the findings: These results suggest the development of sex-specific morphological grading strategies might provide more reliable insights into embryonic potential, increasing the likelihood of selecting a viable embryo for transfer. Consideration of differences in the development of male and female embryos will also be important when developing morphokinetic algorithms for embryo selection.

O-006 Novel and scalable non-invasive metabolic imaging of early embryos using a lab-on-a-chip approach

E. Vargas-Ordaz[1], H. Newman[2], S. Catt[2], R. Nosrati[1], V. Cadarso[1], A. Neild[1], F. Horta[2]

Study question: Is it feasible to safely determine metabolic imaging signatures to measure nicotinamide adenine dinucleotide (NADH) associated auto-fluorescence in early embryos using a scalable lab-on-a-chip approach?

Summary answer: We developed an optofluidic device capable of non-invasively obtain high-resolution 3D images of the metabolic activity of live mouse embryos using a lab-on-a-chip approach.

What is known already: Selecting the most suitable embryos for implantation and subsequent healthy live birth is crucial to the success rate of assisted reproduction and offspring health. Thus, developing non-invasive methods that are reliable to assess oocyte and embryo quality has been a significant aim for assisted reproduction. Besides morphological evaluation using optical microscopy, a promising alternative is the non-invasive imaging of live embryos to establish metabolic activity performance. However, metabolic imaging has been only achieved using highly complex advanced microscopy such as Fluorescence-lifetime imaging (FLIM) and hyperspectral microscopy, methods that are costly and challenging, limiting the potential for deployment in fertility clinics.

Study design, size, duration: The non-invasive nature of the system was investigated by assessing the development and viability of live embryos after embryo culture for 67hrs post metabolic imaging at the 2-cell embryo stage ($n = 115$), including a control for culture conditions and sham controls (system no-illuminated). Embryo quality of developed blastocysts was assessed by immunocytochemistry to quantify trophectoderm and inner mass cells ($n = 75$). Furthermore, inhibition of metabolic activity (FK866 inhibitor) during embryo culture was also assessed ($n = 18$).

Participants/materials, setting, methods: Optofluidic devices were manufactured by cast-moulding using a negative photoresist (SU8-2075; MicroChemicals GmbH, Ulm, Germany) by a standard UV-photolithography process. The microstructures fabricated of polydimethylsiloxane (PDSM) integrated Light Sheet Fluorescence Microscopy into a microfluidic system, including on-chip micro-lenses to generate a light sheet at the center of a microchannel. Super-ovulated F1 (CBA/C57Bl6) mice were used to produce 2-cell embryos and embryo culture experiments. Blastocyst formation rates and embryo quality (immunocytochemistry) were compared between study groups.

Main results and the role of chance: The optofluidic device was capable of non-invasively obtaining high-resolution 3D images of the metabolic activity in live mouse embryos. The system's design allowed continuous tracking of the embryo location, including high control displacement through the light-sheet, fast imaging of the embryos (<2 second) and keeping a low dose of light exposure (16 J cm^{-2} and 8 J cm^{-2}). Optimum settings for keeping sample viability showed that a modest light dosage was capable to obtain 30 times higher signal-noise-ratio images than images obtained with a confocal system ($p < 0.00001$; t-test). The results showed no significant differences between the control, illuminated and non-illuminated embryos (sham control) for embryo development as well as embryo quality at the blastocyst stage ($p > 0.05$; Yate's chi squared test). Additionally, embryos with inhibited metabolic activity showed decreased blastocyst formation rates as well as 47% reduction in metabolic activity measured by non-invasive metabolic imaging ($p < 0.0001$; t-test). This study reports an optofluidic device capable of non-invasive metabolic imaging of live embryos using a similar concept as previously reported using FLIM technology and hyperspectral microscopy, but allowing a novel, scalable and affordable system with implementation potential in standard IVF laboratory equipment.

Limitations, reasons for caution: The study was conducted using a mouse model focused on early embryo development. Further safety studies are required to assess embryonic health by investigating the impact of the use of light during embryo development, live birth, embryo gene expression and epigenome stability.

Wider implications of the findings: This lab-on-a-chip is novel, scalable and has the potential to be used in fertility clinics as a technology platform to enable real-time monitoring of the metabolic function of embryos prior embryo transfer. Future applications include potential integration into existing IVF laboratory equipment such as bench and time-lapse incubators.

O-007 Association of successful embryo development and pregnancy outcome with redox state as measured by human non-mercaptalbumin in embryo culture medium

Y. Kusumoto[1,2,3], M. Sato[3,4], K. Yasukawa[3], B. Uranbileg[3], H. Ikeda[3], Y. Yatomi[3]

[1]*Sakurajyuji Women's Clinic Shibuya, Culture section, Tokyo, Japan*
[2]*Akihabara ART Clinic, Culture section, Tokyo, Japan*
[3]*The University of Tokyo, Department of Clinical Laboratory Medicine- Graduate School of Medicine, Tokyo, Japan*
[4]*The University of Tokyo, Department of Gastroenterology- Graduate School of Medicine, Tokyo, Japan*

Study question: Is the redox state in the embryo culture medium, as measured by oxidized albumin, associated with successful embryo development and pregnancy outcome?

Summary answer: The level of oxidized albumin in the culture medium was the most important variable in predicting blastocyst formation andwas associated with miscarriage after transfer.

What is known already: Human serum albumin (HSA), the most abundant protein in the plasma, exerts important antioxidant activities against oxidative damage. HSA exists as oxidized human non-mercaptalbumin (HNA) and reduced human mercaptalbumin. HNA is attracting attention because of its

novel role as a marker reflecting oxidative state, and HNA levels are known to increase in oxidative stress diseases such as kidney disease, diabetes, liver disease or Parkinson's disease. On the other hand, in human IVF, most culture medium are supplemented with HSA as a protein source, but no previous studies have examined the relationship between HNA and IVF outcomes.

Study design, size, duration: We followed the pregnancy outcomes for 40 cycles of single blastocyst transfer out of the retrospective study, which enrolled a total of 173 embryos cultured to the blastocyst stage from a total of 91 patients who underwent IVF/ICSI cycle between February 2018 and July 2018.

Participants/materials, setting, methods: Prior to using the medium for embryo culture, the redox state was assessed with HNA level. HNA level, patient age, IVF/ICSI and oocyte maturity were analyzed as factors associated with blastocyst formation on day 5 and 6 after fertilization, and a machine learning model was developed by using the Random Forest (RF) algorithm to predict blastocyst formation. We also examined whether the factors made a difference in pregnancy outcomes.

Main results and the role of chance: The median %HNA in the culture medium was 89.36% (range, 80.12% to 94.84%), which was much higher than the value for blood in healthy humans, (approximately 25%). Blastocyst formation was observed in 41.04% (71/173) embryos. In both univariate and multivariate analyses, successful blastocyst development was associated with a lower %HNA in the culture medium ($p = 0.001$), a younger patient age ($p < 0.001$), and the use of standard IVF ($p = 0.007$). A prediction model for successful blastocyst formation was developed using a RF algorithm with four factors (%HNA, patient age, fertilizationmethod, and oocyte maturation stage). The RF model developed using 70% of samples (training set, n = 121) was validated in the remaining testing set (n = 52) and produced an area under the curve of 0.761, where %HNA in the culture medium was the most important variable for the prediction of blastocyst formation, followed by patient age. The HNA levels were significantly higher in the group of embryos that resulted in miscarriage after blastocyst transfer (93.15% vs. 89.28%, $P = 0.0498$).

Limitations, reasons for caution: This study was conducted in G-TL medium only. Further studies are needed to elucidate the association of %HNA and embryo development, and to predict the transfer success rate by using other commonly used media.

Wider implications of the findings: In the IVF medium, which is supposed to mimic the body environment, the %HNA showed a high oxidized state compared to the body itself; it is suggesting it may cause unsuccessful IVF results and lower live birth rate. Controlling the oxidation level may help to create a more appropriate environment.

O-008 The composition of commercially available human preimplantation embryo culture media

M. Zagers[1,2], M. Laverde[1,2], F. Schrauwen[3], J. De Groot[3], F. Vaz[4], S. Mastenbroek[1,2]

[1]Amsterdam UMC location University of Amsterdam, Center for Reproductive Medicine, Amsterdam, The Netherlands
[2]Amsterdam Reproduction and Development, Preconception and Conception, Amsterdam, The Netherlands
[3]Amsterdam UMC location University of Amsterdam, Department of Clinical Chemistry- Laboratory General Clinical Chemistry, Amsterdam, The Netherlands
[4]Amsterdam UMC location University of Amsterdam, Department of Clinical Chemistry- Laboratory Genetic Metabolic Diseases, Amsterdam, The Netherlands

Study question: What is the composition of currently available commercial human preimplantation embryo culture media from eleven different brands for each stage of preimplantation embryo development?

Summary answer: Besides similarities in embryo culture medium composition between brands, there were also differences in composition for which there does not seem to be a rationale.

What is known already: Although a lot remains uncertain, there seems to be some consensus in the scientific literature on the environmental and nutritional needs of preimplantation embryos in *in vitro* culture, at least for certain components. Since suppliers do not disclose the exact formulations of their media, it is unclear whether the embryo culture media currently used in IVF laboratories meet these suggested conditions. We previously published composition analyses of a limited number of culture media, but have now repeated this analysis and have included a larger number of media from eleven brands of human preimplantation embryo culture media.

Study design, size, duration: Forty-seven human embryo culture media and protein supplements were purchased between December 2019 and June 2020. Upon arrival, each complete medium (n = 23), unsupplemented medium (n = 14), and supplement (n = 10) was aliquotted in Eppendorf tubes, snap frozen in liquid nitrogen and stored in -80°C until composition analysis in November 2021. Additionally, unsupplemented media were supplemented with each available supplement from the same brand (n = 33 combinations) and then also aliquotted, snap frozen and stored in -80°C until analysis.

Participants/materials, setting, methods: The concentration of forty components was determined in all collected samples (n = 80). Seven ions, glucose, three immunoglobulins, uric acid, alanine aminotransferase (ASAT), aspartate aminotransferase (ALAT), albumin, and the total amount of proteins were determined in each sample using a Cobas 8000 Analyser (Roche Diagnostics). Analysis of pyruvate, lactate, carnitine and twenty-one amino acids was achieved with Ultra-high Performance Liquid Chromatography-Mass Spectometry (UPLC-MS/MS).

Main results and the role of chance: Our analysis of the concentration of 40 components in ready to use embryo culture media of most available brands on the market showed that in general the culture media follow generally accepted assumptions on the changing needs of an embryo during early development. However, there were clear differences between brands, and no two embryo culture media were the same. For example, pyruvate concentrations were higher in fertilization and cleavage stage media and lower in blastocyst stage media, whereas glucose was relatively high in fertilization media, lower in cleavage stage media, and higher again in blastocyst media. This follows previous findings that demonstrate that pyruvate is the main energy source until blastocyst stage and that glucose becomes the main energy source for blastocysts. Other components, like lactate for example, followed different patterns in the sequential media of different brands, and concentrations also differed between brands. The composition of continuous media resembled the composition of the other media of the same brand, but differed between brands. Interestingly, some of the culture media brands belong to the same parent company, but differ in their composition. The rationale of such differences is not clear. Research providing such rationale seems warranted.

Limitations, reasons for caution: The analysed embryo culture media may contain other components that were not investigated in this study.

Wider implications of the findings: Detailed information on human embryo culture medium composition, including the exact concentrations of each ingredient, is much needed to in the end be able to understand its effect on IVF outcomes, and to facilitate the scientific improvement of media for human preimplantation embryo culture.

Study question: The goal of this study was to determine the independent effect of ethnicity on adverse obstetrical outcomes in women with Polycystic Ovary Syndrome (PCOS).

Summary answer: Among women with PCOS, African Americans, Hispanic and Asians are at an increased risk of certain adverse obstetrics outcomes, whereas Caucasians have fewer pregnancy complications.

What is known already: Polycystic ovarian syndrome is associated with an increased risk of pregnancy complications possibly due to the insulin resistance inherent in this syndrome. Variable ethnicities demonstrate different magnitudes of insulin resistance and in non-PCOS populations are known to be at modified pregnancy complication risks. Different ethnicities may have different phenotypes of PCOS, possibly further modifying outcomes. The role of ethnicity in women with PCOS and its effect on pregnancy complications has not been well studied.

Study design, size, duration: This retrospective population-based study utilized data from the Healthcare Cost and Utilization Project Nationwide Inpatient Sample (HCUP-NIS), over 11 years from 2004 to 2014. The data are representative of 20% of admissions to US hospitals and geographically represent over 96% of the American population.

Clinical modification ICD9-CM codes were used to identify women with PCOS and group them according to maternal ethnicity. In 2015 codes were changed to ICD-10 which are not comparable.

Participants/materials, setting, methods: All women with PCOS($n = 12782$) were grouped according to maternal ethnicity: Caucasian(9107), African American(1098), Hispanic(1288), Asian(741), and other. Pregnancy, delivery, and neonatal outcomes were collected per group and compared to the rest.

Chi-square tests were used to compare the baseline characteristics between the cohorts. Logistic regression analyses were conducted to explore associations between ethnicity and pregnancy outcomes through the estimation of odds ratio (OR) and 95% confidence intervals (CI) while controlling for confounding effects.

Main results and the role of chance: PCOS was found in 12,782 patients with included ethnicity results. Asian women had a higher prevalence of gestational diabetes(GDM) (aOR1.96, 95%CI 1.49-2.58, $p < 0.001$), chorioamnionitis (aOR3.41, 95%CI 2.12-5.47, $p < 0.0001$), operative vaginal delivery (aOR2.42, 95%CI 1.65-3.56, $p < 0.001$), postpartum hemorrhage(PPH) (aOR2.07, 95%CI 1.25-3.43, $p = 0.004$) and maternal infection (aOR2.84, 95%CI 1.80-4.49, $p < 0.001$). African Americans had a higher risk of pregnancy-induced hypertension (aOR1.38, 95% CI 1.06-1.80, $p = 0.02$), preeclampsia (aOR1.68, 95% CI 1.15-2.45, $p = 0.007$), preterm premature rupture of membrane (aOR2.75, 95%CI 1.58-4.78, $p < 0.001$), chorioamnionitis (aOR1.83, 95%CI 1.12-2.98, $p = 0.016$) and cesarean sections (aOR1.69, 95%CI 1.32-2.15, $p < 0.001$) and lower risk of operative vaginal delivery (aOR0.53, 95%CI 0.31-0.93, $p = 0.03$), spontaneous vaginal delivery (aOR0.67, 95%CI 0.52-0.85, $p < 0.001$), and maternal infection (aOR1.91, 95%CI 1.21-3.00, $p = 0.005$). The risk of GDM (aOR1.36, 95%CI 1.06-1.73, $p < 0.014$) and PPH (aOR1.58, 95%CI 1.01-2.47, $p = 0.045$) was increased among Hispanic patients. Caucasian patients were at lower risk of GDM(aOR0.67, 95%CI 0.57-0.79, $p < 0.0001$), chorioamnionitis (aOR0.39, 95%CI 0.28-0.55, $p < 0.0001$), casarean section (aOR0.83, 95%CI 0.73-0.95, $p < 0.008$), spontaneous vaginal deliveries (aOR1.25, 95% CI1.10-1.43, $p < 0.001$), PPH (aOR0.70, 95% CI0.50-0.98, $p < 0.035$), blood transfusion (aOR0.49, 95%CI 0.29-0.83, $p < 0.007$), maternal infection (aOR0.34, 95% CI 0.27-0.51, $p < 0.0001$) and small for gestational age infants (aOR0.64, 95%CI 0.44-0.93, $p < 0.018$). Rates of other pregnancy outcomes were similar for the groups.

Limitations, reasons for caution: This is a retrospective analysis utilizing an administrative database that relied on the accuracy and consistency of the individuals coding the data. There are known limitations to how accurately hospital coding is able to capture perinatal conditions and complications.

Wider implications of the findings: Our study demonstrated that among women with PCOS, specific ethnicities are at an increased risk of adverse obstetric outcomes. This underlines the importance of screening for certain pregnancy complications in PCOS women of African American, Hispanic, and Asian ethnicity. Studies should evaluate the role of insulin resistance in these outcomes.

Trial registration number: not applicable - This study used publicly accessible, anonymized data; therefore, according to articles 2.2, 2.4 of Tri-Council Policy Statement (2010), institutional review board approval was not required.

[7]University of Sheffield and Sheffield Teaching Hospitals, Gynaecology & Reproductive Medicine, Sheffield, United Kingdom

Study question: Is transvaginal ULTRAsound (TVUS)-guided ovarian ablation using May Health device feasible, safe, and effective in inducing ovulation in Clomiphene citrate and/or Letrozole (CC/LTZ)-resistant PCOS women?

Summary answer: TVUS-guided ovarian ablation using the May Health device seems feasible, safe and effective in inducing ovulation in PCOS-related anovulatory infertility, with additional, larger studies needed.

What is known already: Laparoscopic ovarian drilling (LOD) is widely accepted and recommended as an effective second line treatment in PCOS-related infertility. However, it is an invasive procedure that requires general anaesthesia and carries significant risks. Furthermore, the off-the-shelf devices used for LOD are not specifically designed to precisely deliver the desired and effective amount of ablation. In contrast, the May Health device has been designed to induce a precisely calculated amount of ovarian ablation via a much less invasive route without general anaesthesia. May Health therefore transforms an invasive surgical procedure to an office-based technique similar in access to the well-established oocyte retrieval.

Study design, size, duration: This study included two phase-1 feasibility, single-arm clinical trials running in parallel in the US and EU assessing the May Health Device in performing TVUS-guided ovarian ablation in anovulatory PCOS women resistant to first-line ovulation induction drugs. Sample size was 35 participants with post-procedure follow-up (FU) of 24 months in EU and 12 months in US. Endpoints included procedure feasibility (successful ablation of at least one ovary), safety, and effectiveness (ovulation and pregnancy rates).

Participants/materials, setting, methods: Seven fertility centres (UK, France, Belgium, US) participated in the trials. Participants were CC/LTZ-resistant PCOS women aged 18-40 years. PCOS was diagnosed according to Rotterdam criteria. Participants underwent TVUS-guided ovarian ablation using May Health device. The initial five participants underwent laparoscopy concurrent with TVUS-ablation. Post-procedure, serum progesterone was measured weekly until confirmation of ovulation or up to 12 weeks. Women were evaluated at 3 and 6 months, then telephoned at 9, 12 and 24 months.

Main results and the role of chance: Twenty-three participants (mean ± sd age, 31.8 ± 3.1years; BMI, 29.8 ± 5.0kg/m2) underwent May Health TVUS-guided ovarian ablation and completed at least three-months FU. Of those, 10 (43.5%) ovulated spontaneously during the first three months. Six more women ovulated between three- and nine-months FU, some with CC/LTZ, giving a total ovulation rate of 69.6% (16/23). Of the 11 participants who completed nine-months FU, five conceived. Two more participants conceived before 9-months giving a total pregnancy rate of 53.8% (7/13).

In 19 cases (82.6%), ablation was achieved successfully in both ovaries, while in four cases (17.4%) one of the ovaries was not ablated either because it was too small (as per protocol) (n = 3) or inaccessible (n = 1).

Overall, 14 participants experienced 29 adverse events (AEs), of which 25 were mild, two moderate and two severe. Nine mild/moderate AEs were deemed related to the device/ablation procedure. Examples of mild/moderate AEs included mild self-limiting vaginal bleeding (n = 5), pain (n = 5) and headache (n = 2). None of the severe AEs were deemed related to the device/ablation procedure. One participant in phase1a who underwent laparoscopy concurrent with the ablation, sustained a bowel injury involving the ilium near the ileocecal junction. Independent expert investigation concluded that the injury was likely caused by laparoscopic veress needle.

Limitations, reasons for caution: One possible limitation of this study is the lack of a comparator treatment / placebo arm. However, this was not necessary for this feasibility phase 1 trial. Furthermore, given the nature of TVUS-ovarian ablation, it would be difficult to compare it with other ovulation induction drugs or to a placebo.

Wider implications of the findings: These preliminary data suggest that the novel May Health device offers a promising office-based second line ovulation inducing procedure for CC/Letrozole-resistant anovulatory PCOS women.

O-011 Cardiovascular morbidity and mortality in women with PCOS: a cohort study of 75142 participants from the UK biobank

T. Doulgeraki[1], A. Wright[2], H. Frederick[3], C.A. Celis-Morales[4], J.P. Pell[3], N. Sattar[4], S. Iliodromiti[2]

[1]Royal London Hospital, Obstetrics and Gynaecology, London, United Kingdom

[3]University of Glasgow, Institute of Health and Wellbeing, Glasgow, United Kingdom
[4]University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom

Study question: Are women with PCOS at an increased risk of cardiovascular mortality and morbidity?

Summary answer: Although PCOS is strongly associated with cardiovascular risk factors, it does not increase the risk of cardiovascular morbidity and mortality in women aged 40-60 years.

What is known already: PCOS is one the commonest endocrinopathies in women of reproductive age characterised by anovulation, hyperandrogenism and polycystic ovaries in ultrasound surveillance. The prevalence of PCOS has been quoted 8 to13% of women in the UK, however, up to 70% of the cases may be undiagnosed. Women with PCOS are at increased risk of developing adverse cardiometabolic outcomes including insulin resistance, type 2 diabetes (T2DM), metabolic syndrome, hypertension and dyslipidaemia. Those unfavourable risk factors would place women with PCOS at an increased risk for cardiovascular mortality and morbidity, however, the evidence from epidemiological studies are so far heterogenous with conflicting results.

Study design, size, duration: We conducted a cohort study including a total of 75142 participants from the UK biobank, of whom 15747 had PCOS. Women were followed up for 11.1 years in average.

Participants/materials, setting, methods: The primary outcome was morbidity and mortality from ischemic heart disease and stroke. We constructed Cox regression analysis adjusted for confounders and risk factors to quantify the risk of cardiovascular morbidity and mortality in women with PCOS.

Main results and the role of chance: The incidence rate of cardiovascular events was 1.92/1000 person years in the PCOS population and 1.90/1000 person years in women without PCOS. PCOS was associated with a higher risk of obesity (OR 1.63, 95% CI 1.56-1.70), hypertension (OR 1.18, 95% CI 1.13-1.23) and type 2 diabetes (OR 1.44, 95% CI 1.31-1.58). In the adjusted cox regression model, PCOS doesn't increase the risk of CVD morbidity and mortality (HR 0.89, 95% CI 0.78-1.01), however, the cumulative hazard risk in women over 60 years old with a history of PCOS was greater compared to women without PCOS.

Limitations, reasons for caution: The low response rate (5.5%) to the UK biobank recruitment introduces a healthy responder bias which may limit the representation of the population. PCOS was both self-reported and assessed by clinical and biochemical features and other variables were also self-reported, hence reporting bias cannot be excluded.

Wider implications of the findings: The strong association of PCOS with cardiometabolic risk factors and that the CVD morbidity/mortality risk becomes comparable with that of women without PCOS after correcting for these factors, highlights the need to strengthen public health strategies for surveillance, lifestyle interventions and prompt treatment of those co-morbidities in women with PCOS.

O-013 Metabolic characteristics of offspring born to women with polycystic ovary syndrome in childhood

M. Tang[1], Y. Zhu[1]

[1]Women's Hospital- School of Medicine- Zhejiang University, Department of Reproductive Endocrinology, Hangzhou- Zhejiang, China

Study question: Does polycystic ovary syndrome (PCOS) affect the metabolic characteristics of offspring in childhood?

Summary answer: Girls born to PCOS mothers had increased cholesterol (CHOL) and low-density lipoprotein cholesterol (LDL) levels, whereas boys had comparable CHOL and LDL levels to controls.

What is known already: Maternal PCOS status may negatively influence childhood growth, endocrine and metabolic function. The long-term impact of PCOS on children health is poorly understood. Current findings reported by previous studies are divergent. Propensity score matching can reduce bias where strong confounding by indication is expected.

Study design, size, duration: This was a cohort study including 223 singletons born to women with PCOS and 2326 singletons born to non-PCOS women. All offspring were conceived by in-vitro fertilization (IVF) or Intracytoplasmic sperm injection (ICSI) from January 2001 to January 2018 in reproductive center of Women's hospital, Zhejiang University, School of medicine. Growth and development parameters and metabolic parameters were collected at age 3-6 years in Follow-up center of Women's hospital, Zhejiang University, School of medicine.

Participants/materials, setting, methods: We used the propensity score (PS) to match PCOS women and non-PCOS women in a 1:4 ratio. The variables in the PSM included maternal age at conception, paternal age at conception, maternal height, maternal preconception BMI, IVF or ICSI, fresh-embryo transfer (ET) or frozen-embryo transfer (FET), gender of offspring, age at follow-up, year of follow-up. The PCOS group consisted of 217 patients and the non-PCOS group consisted of 787 patients after PS matching.

Main results and the role of chance: Maternal preconception weight (58.3 ± 0.6 vs. 56.0 ± 0.2, $P<0.001$) and body mass index (BMI) (23.0 ± 0.2 vs. 21.9 ± 0.1, $P<0.001$) were significantly higher in mothers with PCOS before PS matching. After PS matching, parental demographic characteristics were similar between groups including maternal preconception weight and BMI. In PS matching cohort, the height, weight, BMI of children at age 3-6 years were comparable between PCOS group and non-PCOS group. Singletons born to PCOS women had significantly higher CHOL levels (4.43 ± 0.05 vs. 4.29 ± 0.01, $P=0.013$) and LDL levels (2.45 ± 0.04 vs. 2.37 ± 0.01, $P=0.049$) compared with non-PCOS group. Even though the girls had similar BMI in childhood between the two groups(15.26 ± 0.15 vs.15.13 ± 0.80, $P=0.449$), the girls born to PCOS women still exhibited elevated CHOL levels (4.52 ± 0.08 vs. 4.33 ± 0.04, $P=0.024$) and LDL levels (2.55 ± 0.06 vs. 2.39 ± 0.03, $P=0.007$). These differences in CHOL (4.34 ± 0.07 vs. 4.26 ± 0.04, $P=0.196$) and LDL levels (2.36 ± 0.05 vs. 2.36 ± 0.03, $P=0.866$) were not observed in male offspring between the two groups.

Limitations, reasons for caution: Mothers' weight gain during pregnancy, offspring lifestyle were not available for this study. This was a study carried out in a single center and was therefore susceptible to bias. Further studies remain necessary to fully confirm these results.

Wider implications of the findings: Our results support CHOL and LDL lipid metabolism as two of the earliest metabolic abnormalities features of the female offspring born to PCOS women. These findings suggest that further studies are needed to investigate the potential mechanisms and long-term metabolic changes associated with these differences.

Trial registration number: not applicable

O-014 Clustering identifies distinct subtypes of PCOS – Towards a Rationale Approach to PCOS classification

K. Van der Ham[1], L. Moolhuijsen[2], K. Brewer[3], R. Sisk[4], Y. Louwers[1], J. Visser[2], A. Dunaif[3], J. Laven[1]

[1]Erasmus Medical Center Rotterdam, Reproductive Medicine and Endocrinology, Rotterdam, The Netherlands
[2]Erasmus Medical Center Rotterdam, Internal Medicine, Rotterdam, The Netherlands
[3]Icahn School of Medicine at Mount Sinai, Division of Endocrinology- Diabetes and Bone Disease, New york, U.S.A.
[4]Northwestern University Feinberg School of Medicine, Division of Endocrinology-Metabolism- and molecular Medicine, Chicago, U.S.A.

Study question: Does unsupervised clustering identify biologically distinct subtypes in a cohort of women with polycystic ovary syndrome (PCOS) diagnosed by Rotterdam criteria?

Summary answer: This study demonstrates that unsupervised hierarchical clustering of eight pre-defined quantitative reproductive and metabolic traits identifies biologically distinct subtypes in women with PCOS.

What is known already: PCOS is a common, heterogeneous, endocrine disorder in women of reproductive-age. PCOS diagnosed by NIH or non-NIH Rotterdam criteria or by self-report is generally genetically similar. Using Hierarchical Clustering (HC), we have previously identified discrete, stable PCOS subtypes, which we designated reproductive (higher LH, FSH, SHBG) and metabolic (higher BMI, insulin, glucose), in a United States cohort of ~900 PCOS women diagnosed by NIH criteria (Dapas *et al. PLoS Med*, 2020). The cases that did not cluster were designated "background subtype". The subtypes appeared to capture biologically meaningful differences because they were associated with distinct and novel genome-wide significant loci.

Study design, size, duration: In the current study, we applied HC to the same traits (BMI, LH, FSH, DHEAS, SHBG, testosterone, fasting insulin and fasting glucose). We then assessed whether additional traits differed between the subtypes thus identified: anti-Müllerian hormone (AMH), total follicle count, modified Ferriman-Gallwey score, estrogen, TSH, DHEA, cortisol, androstenedione, prolactin, LDL, HDL, triglycerides and cholesterol.

Participants/materials, setting, methods: Women of European ancestry, aged 13-45 years, n = 2502, with PCOS according to the Rotterdam criteria were included; n = 1067 also fulfilled NIH criteria. All quantitative traits were log-transformed to approximate a normal distribution. Z-scores were used to compare the differences between the three clusters using ANCOVA, corrected for age. Pair-wise comparison of the different clusters was performed using Fisher's least significance difference method and adjusted for multiple testing.

Main results and the role of chance: We replicated discrete subtypes in this large cohort of women with PCOS defined by the Rotterdam criteria. There were 1026 cases in the metabolic subtype, 450 cases in the reproductive subtype and 1026 in the background subtype. Cases in the reproductive subtype had significantly (all $P<0.001$) higher serum AMH levels, follicle

counts and HDL levels compared to the metabolic and background subtypes. These findings suggest that the reproductive subtype captures affected women with the alterations in folliculogenesis characteristic of PCOS, without using PCOM to define this subtype. In contrast, the cases in the metabolic subtype had significantly (all $P < 0.001$) higher triglyceride and LDL levels compared to the other subtypes providing further evidence that this subtype identifies cases with cardiometabolic risk. Androstenedione and TSH levels were significantly increased in the metabolic subtype compared to the background subtype ($P < 0.001$) and to both subtypes ($P = 0.004$), respectively. Cortisol and prolactin levels did not differ among the three subtypes. All results did not differ when the analysis was limited to NIH PCOS cases. Overall, our findings suggest that these PCOS subtypes have different etiologies and clinical outcomes. Subtyping may enable precision medicine approaches to the management of what is currently classified as PCOS.

Limitations, reasons for caution: A limitation of the study is that we have not replicated these findings in an independent cohort. We have not used an orthogonal method, such as genome-wide association, to confirm that the subtypes capture biologically distinct groups.

Wider implications of the findings: Taken together with our previous studies suggesting that the genetic architecture of these subtypes differs, the current study implies that PCOS consists of several etiologically distinct disorders. Our findings provide an example of the power of modern disease classification based on objective biologic differences rather than expert opinion.

O-015 Spontaneous alterations in semen parameters are associated with age, accessory gland function and the FSHB c.-211G>T variant

M. Zitzmann[1], M. Schubert[1], A. Sansone[2], S. Kliesch[1]

[1]*Centre of Reproductive Medicine and Andrology- University Münster, Department of Clinical and Surgical Andrology, Münster, Germany*
[2]*Chair of Endocrinology and Medical Sexology ENDOSEX, Department of Systems Medicine- University of Rome Tor Vergata, Rome, Italy*

Study question: Which parameters are associated with spontaneous alterations in semen analysis in infertile men?

Summary answer: Changes in semen parameters are modulated by abstinence time, accessory gland function and fluctuations in FSH serum concentration, which is bound to FSHB c.-211G>T variant.

What is known already: There is a strong within-subject alteration of semen parameters in men with infertility. The WHO therefore recommends two ejaculate analyses. However, it remains unknown in which subgroup variations are likely to occur and which semen parameters are affected.

We assume that in some men with idiopathic infertility, ejaculate parameters may spontaneously change without interventional medication apart from regression to the mean effects. The study aims to identify factors in conventional semen analysis based on the patients' clinical data, including reproductive hormones like follicle stimulating hormone (FSH), and factors impacting endocrine activity, like the FSHB-211 promoter gene.

Study design, size, duration: In this retrospective longitudinal study we selected 3456 deeply phenotyped men with idiopathic infertility who had visited our centre for fertility workup from 2010-2020. The patients were selected from our well curated database Androbase© for analysis of repeated ejaculate samples.

Participants/materials, setting, methods: Men with idiopathic infertility and at least two ejaculate analyses (70-90 days distance) were included. Exclusion criteria comprised: sperm concentration <1 million/ml, abnormal FSH or low testosterone, bitesticular volume (bTV) <10ml, orchiectomy, cryptorchidism, varicocele testis, oncological disease, genetic findings (i.e. abnormal karyotype, AZF deletions), medication affecting spermatogenesis.

Grouped linear 2-level nested mixed-effect models were applied. Analyzed parameters included: somatic, hormonal (including FSH and FSHB c.-211 variants), and semen parameters (including abstinence time, accessory gland markers).

Main results and the role of chance: Groups were built according to sperm concentration: A ($n = 397$): ≥1.0 to <5.0 mill/ml, B ($n = 708$): ≥5.0 to <15.0 mill/ml, C ($n = 2351$): ≥15.0 mill/ml.

A, B and C: changes in ejaculate volume were associated with alterations in total sperm count and motility ($p < 0.003$). Changes were, controlled for abstinence time ($p < 0.001$), related to alpha-glucosidase, fructose or zinc ($p = 0.005$-0.02).

A+B: fluctuations in FSH concentration influenced sperm concentration/count ($p = 0.004$-0.02), albeit only in men with FSHB c.-211 GG ($p = 0.007$-0.02). T-allele carriers did not show changes in FSH concentration ($p > 0.1$).

B: age <50 years ($p = 0.007$-0.01) and normal bTV ($p = 0.008$-0.02) were associated with spontaneous increases of sperm concentration, count and motility.

Semen parameters exhibit intra-individual alterations associated with organic, hormonal and genetic variables. Changes are pronounced in younger men with normal bTV and oligo- to almost normozoospermia. The effect is modulated by abstinence time, accessory gland function and fluctuations in FSH concentrations which, in turn, are bound to the FSHB-211 promotor gene polymorphism.

Limitations, reasons for caution: A limitation of our approach is the retrospective nature of the study, which cannot exclude the possibility of bias within the data set.

Wider implications of the findings: Judgement of semen analysis should be based on two semen samples, with abstinence time between 4-5 days. In future clinical trials, abstinence time should be kept constant. It might be investigated if younger men with normal bTV and FSHB c.-211 GT/TT benefit from improving accessory gland function and increasing FSH.

O-016 Sperm motility has declined between 2017 and 2022 among candidate sperm donors in Denmark

R. Montgomerie[1], E. Lassen[2], A.B. Skytte[2], A. Pacey[3]

[1]*Queen's University, Biology, Kingston, Canada*
[2]*Cryos International Sperm and Egg Bank, not applicable, Aarhus, Denmark*
[3]*University of Sheffield, Department of Oncology and Metabolism, Sheffield, United Kingdom*

Study question: Has sperm quality among candidate sperm donors in Denmark changed in recent years (2017-2022)?

Summary answer: Although sperm concentration of candidate donors did not change, sperm quality (motility) declined by ~35% after controlling for age and other potential confounds.

What is known already: Questions remain about whether human sperm quality has declined in recent decades. Whilst some studies support this trend, others dispute it due to potential biases in the populations studied or the different methodological approaches to measuring sperm quality. Resolution of this issue is important because of the implications for human fertility, as well as for those involved in the recruitment of donors for use in Medically Assisted Reproduction.

Study design, size, duration: We analyzed the semen quality of 6,774 candidate sperm donors attending for their first semen analysis at Cryos International from 2017 to 2022 at four cities in Denmark: Aarhus, Aalborg, Copenhagen, and Odense. We analyzed only the first sperm sample, whether or not the candidate was eventually accepted as a donor. All donor

candidates were between 18 and 46 years old and lived in or near these four cities.

Participants/materials, setting, methods: Ejaculates were examined within one hour of production. Semen volume (mL) was estimated by weight and both total sperm concentration (10^6/mL) and the concentration of grade A and B spermatozoa were measured using the same protocols and CASA-system across all years at each site. Analyses were controlled for age, site, ejaculate volume, and the average monthly temperature when the ejaculate was produced. We used longitudinal data from accepted donors to test for methodological biases.

Main results and the role of chance: From 2017 to 2022, there was no evidence of changes in either semen volume (median = 3.5 mL) or sperm concentration (median = 58 million/mL) in the ejaculates of candidate donors. There was, however, clear evidence of a decline in the concentration (and total number) of grade A and B motile sperm. For the average candidate sperm donor that we studied, the concentration of grade A sperm declined from 5.15 [95% CL: 4.18, 6.34] million/mL in 2018 to 3.33 [2.71, 4.08] million/mL in 2022. This corresponds, for example, to a predicted decline in sperm quality of ~35% for a 25-year-old candidate from Aarhus in a month when the average daily high temperature was 18.5 °C. The same pattern was evident from all four cities, but candidates at Aarhus had lower overall sperm quality (grade A sperm motility) than candidates at the other three cities. Analysis of the longitudinal data from repeated donations from all 'accepted' donors during this same period (2017 – 2022), allowed us to rule out methodological factors (sperm collection, CASA, statistical anomalies) that might have influenced these findings.

Limitations, reasons for caution: We cannot rule out the possibility that men with poor sperm quality were more likely to apply to be donors during the global pandemic, or that the lifestyles of candidate donors had changed during this period because of lockdowns or changes in work patterns.

Wider implications of the findings: Candidate sperm donors are a useful population in which to monitor changes in human semen quality over time. The results may have implications for human fertility and the recruitment of sperm donors, where motile sperm concentration is an essential selection criterion.

Trial registration number: not applicable

O-017 A novel diagnostic test identifies patients suffering from loss of CatSper function

S. Young[1], C. Schiffer[1], A. Wagner[1], J. Patz[1], A. Potapenko[1], L. Herrmann[1], T. Pock[1], B. Stallmeyer[2], A. Röpke[2], V. Nordhoff[1], H. Behre[3], S. Kliesch[1], F. Tüttelmann[2], C. Brenker[1], T. Strünker[1]

[1]*University of Münster, Centre of Reproductive Medicine and Andrology, Münster, Germany*
[2]*University of Münster, Institute of Reproductive Genetics, Münster, Germany*
[3]*University of Münster, University Hospital Münster Fertility Clinic, Münster, Germany*

Study question: Is a loss of CatSper function in sperm a common cause of unexplained male infertility?

Summary answer: Loss of CatSper function leads to similar infertility phenotypes in mice and men and represents one of the most common causes of unexplained male infertility.

What is known already: Male infertility is often due to low sperm counts, impaired motility, and/or abnormal morphology. However, for a large fraction of infertile men, semen parameters are normal, suggesting that the infertility is rather due to an unexplained dysfunction of the sperm. There has been a growing body of evidence that human sperm dysfunction might involve the sperm-specific Ca^{2+} channel CatSper (cation channel of sperm) that translates changes in the chemical microenvironment of the female reproductive tract into changes in swimming behavior.

Study design, size, duration: In an observational study over the course of three years, a prototype of the "CatSper-Activity-Test" (CAT) was used to assess the function of CatSper in sperm from the left-over semen samples of 2286 unselected patients undergoing a semen analysis.

Participants/materials, setting, methods: The CatSper-Activity-Test (CAT) was developed at the Centre of Reproductive Medicine and Andrology, University Hospital Münster and subsequently performed by medical technical assistants in the diagnostic facility of this institution. Requiring only 40 µl of ejaculate, a standard light microscope, and a hands-on-time of a few minutes, the CAT enables a read-out of the activity of CatSper through a motility response: in the CAT buffer, CatSper-intact, but not CatSper-deficient sperm become immotile.

Main results and the role of chance: Using this CatSper-Activity-Test, we identified seven patients suffering from a loss of CatSper function in a cohort of men seeking medical advice for suspected male infertility. Standard semen analysis revealed that the CatSper-deficient patients are (with one exception) normozoospermic and were diagnosed with unexplained infertility. Notably, their sperm not only failed to fertilize the egg naturally but also upon intrauterine insemination (IUI) and in vitro fertilization (IVF), whereas intracytoplasmic sperm injection (ICSI) was successful. Two additional CatSper-deficient patients were identified among patients visiting our clinics for other reasons. We show that the loss of CatSper function is predominantly caused by a homozygous deletion of the *CATSPER2* gene; one patient featured compound heterozygous variants of the *CATSPERE* gene. According to the study results, CatSper dysfunction underlies 1.7% of cases of unexplained male infertility, for which a female factor can be excluded.

Limitations, reasons for caution: Results from this observational study were obtained from a single institute. A multi-center study involving various countries would enable a more precise determination of the prevalence of CatSper-related male infertility.

Wider implications of the findings: The CatSper-Activity-Test reliably identifies CatSper-deficient patients with a hands-on-time of a few minutes and requires neither special equipment nor specific training. We envisage the CatSper-Activity-Test as a novel tool for the early diagnosis of male infertility, thus, contributing to evidence-based treatment decisions and sparing patients unnecessary medical and financial risks.

O-018 Impact of atypical bacterial semen infections on spermocytogram parameters and Spermatozoa DNA fragmentation and denaturation

M. Benkhalifa[1], W. Zidi[2], H. Bahri[1]

[1]*HB laboratory, Andrology / Reproductive Biology, Tunis, Tunisia*
[2]*Faculty of Sciences of Bizerte. Carthage University, Physiology, Tunis, Tunisia*

Study question: Does Spermocytogram parameters and Spermatozoa-DNA-Fragmentation (SDF) / Denaturation (SDD) levels are affected by atypical-bacterial semen infections in North-African men during the period between 2013-2022?

Summary answer: SDD presented positive-correlations with the presence of 3/5 atypical bacteria in the semen. Various Spermocytogram-parameters were also found to be negatively associated with atypical-bacterial-semen-infection.

What is known already: Atypical-Bacterial semen infections such as infections by Chlamydia-trachomatis (CT), Mycoplasma-hominis (MH) and genitalium (MG), Ureaplasma urealyticum (UU) and parvum (UP), were shown to be associated with poor sperm function (Prabha.et.al.,2009; Agarwal.et.al.,2012). In infections caused by CT, SDF was observed to be increased significantly and associated with male infertility (Karinen.*et.al.*,2004; Gallegos.et.*al.*,2008). In addition, MH and UU appeared to cause induction of nuclear decondensation and SDD, which damages sperm and has effects on sperm parameters. However, other studies failed to show any effect of MH, UU and CT on sperm parameters and SDD (Lee.et.al.,2013; Gdoura.et.al.,2008; Huang.et.al.,2015; Farsimadan and Motamedifar,2020).

Study design, size, duration: Retrospective study, including Sperm-culture-analyzes, Spermocytograms and SDF/SDD tests performed between

January,2013 and December,2022 of 10.386 patients from North-Africa aged between 19 and 73 years-old (y.o) (average-age: 43.2 y.o ± 7.16). Patients were classified in 2 main groups according to the presence (Group-1: n = 613) or not (Group-2: n = 9773) of atypical-bacteria in the semen and 5 subgroups of monobacterial-infected-semen which were extracted from Group-1 as: CT (n = 14), MH (n = 61), MG (n = 10), UU (n = 147) and UP (n = 73) subgroups.

Participants/materials, setting, methods: 8201-Tunisian-patients(79%), 1142-Algerians(11%) and 1038-Libyans(10%) presented for semen-analyzes. Samples were analyzed according to World-Health-Organization (WHO) guidelines. Bacterial-semen-infection was detected by real-time-polymerase-chain-reaction(RT-PCR). Spermocytogram analyzes were performed according to WHO2010-recommendations using Sperm-class-analyzer-software (SCA5/6(CASA-system)) and SCA-scope (Microptic®). SDF analyzed with terminal-uridine-nucleotide-end-labeling(TUNEL)/sperm chromatin dispersion(SCD) techniques. SDD analyzed with the Aniline-Blue-staining-method. Statistical-analyzes were performed using SPSS22.0 for Windows-software. Kolmogorov–Smirnov-test for normality-analysis and comparisons by Student-t-test/Mann–Whitney U-test, as appropriate. Pearson/Spearman' tests for correlations were used as appropriate, *P-value*<0.05 was considered as significant.

Main results and the role of chance: Sperm concentration was significantly lower in atypical-bacterial-semen-infected-group (Group-1) compared to controls (Group-2) with 11.39[0-311] vs 20.06[0-694]x10^6spz/mL, (p = 0.014); respectively, as well as progressive motility (14.6%[0%-64.47%] vs 21.89%[0%-81.35%], (p = 0.002); respectively) and typical morphology (5.34%[0%-18%] vs 9.29[0%-21%] (p < 0.001); respectively). However, Leucocytes concentration and SDD presented significant higher levels in Group-1 compared to Group-2 with 1.8[0.1-8.5] vs 0.5[0.1-2.45]x10^6 leucocytes/mL, (p < 0.001) and 21%[4%-60%] vs 15%[2%-75%], (p = 0.04); respectively. Similar significant differences were observed with 3/5 of the monobacterial-semen-infected-subgroups in comparison with Group-2 (MH, UU and UP-subgroups). No significant differences were observed in MG and CT-subgroups in except of SDD which presented significant higher levels in CT-subgroup in comparison with Group-2 (52%[4%-85%] vs 15%[2%-75%], (p = 0.002);respectively). Correlation-analyzes showed that SDD was positively correlated to MH (r = 0.069; p = 0.022) and UU (r = 0.084; p = 0.005) which is in accordance with the study of .Lee.et.al.(2013). Leucocytes concentration was also correlated positively to MH, CT, UU and UP (r = 0.047; p<0.001; r = 0.035; p=0.005; r = 0.074; p<0.001; r = 0.045; p=0.05; respectively). Sperm concentration, Progressive motility and Typical morphology presented Negative correlations with MH (r=-0.038; p=0.034; r=-0.048; p=0.05; r=-0.047; p=0.05; respectively), UU (r=-0.034;p=0.003; r=-0.04; p<0.001; r=-0.067; p=0.007; respectively) and UP (r=-0.072; p<0.001; r=-0.078; p=0.018; r=-0.057; p<0.05; respectively). Our results are in accordance with other studies such as of Prabha.et.al.(2009) and Agarwal. et al. (2012). However, SDF did not show any significant variation between our studied groups.

Limitations, reasons for caution: Our study is a retrospective-statistical survey that included patients presenting to the laboratory for fertility diagnosis or for a diagnosis due to a pathology and/or inflammation of the genital tract. Meta-analysis studies in addition to more prospective-randomized-controlled-trials in collaboration with IVF or other medical-analyzes-laboratories are necessary to confirm/refute our results.

Wider implications of the findings: These results should interest urologists, microbiologists, gynecologists, reproductive science fundamentalists, epidemiologists and embryologists who want to improve the investigations on the relationship between bacteria and semen parameters to the reasons of infertility, recurrent miscarriages and poor quality embryos in IVF.

Trial registration number: Not applicable

O-019 Decreased Sperm Motility Associated With Bacterial Vaginosis Modeled in a Human Cervix Chip

O. Gutzeit[1], Z. Izadifar[1], A. Gulati[1], A. Junaid[1], A. Stejskalova[1], S. Lee Marquez[1], K. Shcherbina[1], G. Goyal[1], D.E. Ingber[1]

[1]*Harvard, Wyss Institute, Boston, U.S.A.*

Study question: What is the underlying cause of infertility associated with bacterial vaginosis (BV)?

Summary answer: We provide the first evidence to suggest that BV-associated infertility could be the result of sperm dysfunction induced by exposure to poor cervical microbiome.

What is known already: Infertility is a global health concern, impacting 186 million individuals worldwide. In 25% of infertile couples the underlying cause remains unexplained. The complex interactions between the host mucosal epithelium, microbiome, and other microenvironmental factors play a significant role in health and disease of the reproductive tract. BV affects 30% of reproductive-aged women and is linked to overgrowth of pathogenic *Gardnerella vaginalis* bacteria. BV has a strong association with infertility, but it is not clear whether the resulting changes in the vaginal microbiome play a causal role, and as such BV screening is not currently included in infertility evaluation or treatment

Study design, size, duration: Female reproductive tract protective factors such as cervical mucus helps sperm retain their ability to fertilize for days compared to hours in suspension. We previously leveraged human organ-on-a-chip microfluidic culture technology to develop a physiological in vitro model of human cervix (Cervix Chip) that is lined with primary cervical epithelium interfaced with stromal fibroblasts. The epithelium forms a functional tissue barrier and produces mucus with compositional, biophysical, and hormone-responsive properties similar to the living cervix.

Participants/materials, setting, methods: We used 2D culture of sperm and bacteria as a screening and validated the effect of the identified bacteria on physiological in vitro Cervix Chip. A BV consortium containing E2 and E4 *Gardnerella vaginalis* bacteria was co-cultured with the Cervix Chip for 48 hours before adding human sperm samples. The motility of fluorescently labeled sperm was non-invasively evaluated in live chips using time-lapse imaging and quantitatively analyzed to obtain the percentage of motile sperm.

Main results and the role of chance: We initially analyzed the effects of bacterial co-cultur *L. crispatus* (optimal) or *G. vaginalis* (suboptimal) bacteria on sperm motility using a conventional 2D culture system. We observed a significant drop in sperm motility within 2 hours when exposed to *G. vaginalis* compared to *L. crispatus* or the control condition (no bacteria). We have established sperm staining and live tracking on Cervix Chip. Motile sperm was tracked on Cervix Chip for more than 7 days compared to 12 hours in suspension. We then tested this effect on-chip and observed that co-culture of live sperm with dysbiotic Cervix Chip (infected with *G. vaginalis*) resulted in a significant reduction in the sperm motility within 24 hours after exposure compared to the sperm exposed to the chips without bacteria. The dysbiotic Cervix Chip also exhibited a disease phenotype with elevated levels of proinflammatory cytokines including IL-1α, IL-1β, IL-6, IL-8, and TNF-α in the effluents of the chip's epithelial channel as well as significantly reduced thickness of the cervical mucus layer that correlated with reduced sperm motility. This finding is consistent with the observation that successful fertility is often associated with the quality of cervical mucus, which can be compromised in the BV dysbiotic condition.

Limitations, reasons for caution: Primary cervical epithelium cells used in the study were sourced from a single donor. Frozen sperm samples prepared for intrauterine insemination were used in the study

Wider implications of the findings: Our study suggests that infertility related to BV may be caused by sperm dysfunction, and BV screening should be considered in patients with unexplained infertility. We propose a model that can be used to identify dysbiotic conditions in the female reproductive tract that are unfavorable to sperm motility.

O-021 The dose of micronised vaginal progesterone prior to frozen embryo transfer in artificially prepared cycles: the more the better?

E. Bumbul-Mazurek[1,2], C. Roelens[1], S. Mackens[1], L. Van Landuyt[1], P. Drakopoulos[1,3], H. Tournaye[1], C. Blockeel[1]

[1]*Universitair Ziekenhuis Brussel- Brussels- Belgium, Brussels IVF, Brussels, Belgium*
[2]*Medical University of Warsaw, 1st Department of Obstetrics and Gynaecology, Warsaw, Poland*
[3]*IVF Athens, IVF Athens, Athens, Greece*

Study question: Does a higher daily dose of micronized vaginal progesterone (MVP) increase live birth rates (LBR) or diminishes risk of early pregnancy loss (EPL)?

Summary answer: An increased dose of MVP does not affect reproductive outcomes.

What is known already: Endometrial preparation in frozen embryo transfer (FET) cycles can be achieved either in a natural cycle (NC), a stimulated cycle or an artificial cycle (AC). Despite growing advocacy for utilization of NC for FET mainly because of pregnancy complications, there are still numerous indications and strengths of AC, such as convenient monitoring and planning. In AC-FET cycles exogenous estradiol (E2) and progesterone (P) are administered consecutively in order to mimic a natural cycle. Although MVP still being the most widely used medication for LPS in AC-FET cycles, dose finding studies are lacking.

Study design, size, duration: This is a retrospective study performed at a university-affiliated centre including patients performing a single blastocyst transfer from January 2016 till June 2021. Pregnancy outcomes were compared between patients receiving 600mg (3x200mg) or 800mg (2x200mg) of MPV in the second phase of an AC-FET cycle. The time period was chosen to incorporate the empiric change made in the inner guidelines regarding artificial cycles LPS in autumn 2018.

Participants/materials, setting, methods: Patients aged 19-39, who underwent the first frozen single blastocyst transfer were included. Only HRT cycles, where after exogenous estradiol endometrium preparation LPS was started with MVP 600mg or 800mg were included. Patients lost to follow-up, with missing data, with known uterine pathology, recurrent miscarriages, with switch to MNC, with more than one progesterone route planned or modified LPS were excluded.

Main results and the role of chance: 1825 artificial cycles for FET were included. 827 supplemented with 600mg of MVP -MVP600 group and 998 with 800mg of MVP – MVP800 group. The MVP600 and MVP800 groups did not differ in BMI 24.02 (SD 4.73) vs 23.81 (SD 4.6) ($p = 0.37$), rank of embryo transfer 1.93 (SD 1.41) vs 1.77 (SD1.19) ($p = 0.11$), or the thickness of the endometrium at planning 8.67mm (SD1.79) vs 8.51mm (SD 1.7) ($p = 0.06$). Yet, MVP 800mg group was slightly older than MVP600 group 31.99 (SD 3.72) vs 30.84 (SD 3.9) ($p < 0.001$). Positive hCG was 58.65% (485 out of 827) for MVP600 and in 62.12% (620 out of 998) for MVP800 group ($p = 0.13$). LBR per positive hCG 64.18% (292 out of 455) in MVP600 and 67.17% (397 out of 591) in MVP800 group ($p = 0.31$). Early pregnancy loss per positive hCG did not differ between the groups, and including biochemical losses, was 32.75% in MVP600 (149 out of 455) vs 30.8% in MVP800 (182 out of 591) ($p = 0.5$). Multivariable regression analysis adjusting for relevant confounders (eg. BMI, endometrium thickness) revealed that the dose of

MVP 600mg vs 800mg is not significantly associated with EPL OR 0.92 (95% CI 0.71-1.22) p > 0.592.

Limitations, reasons for caution: The main limitation is the retrospective design of our study, with an inherent risk of bias. Furthermore, we could not compare the blood progesterone values at the day of the transfer as in MVP600 they were not routinely performed, so the need for additional LPS could not be compared.

Wider implications of the findings: This is the largest study dose finding study comparing the two progesterone administration doses. The higher dose of MVP does not improve reproductive outcomes, but might be more convenient due to a twice daily application.

O-022 Shall we go "natural" for endometrial preparation in egg donation programs? Live birth rates and obstetrical outcome from 797 frozen single-blastocyst transfers cycles

F. Moffa[1,2], A. Garcia-Faura[1,2], S. Novo[1,2], A. Perez-Alzueta[1], L. Acin[1,2], A. Moreno[1], L. Peinado[1,2], P. Ruiz[2], F. Lolicato[1,2], S. Rovira[1,2], M. Antic[1,2]

[1]Fertilab, Assisted Reproduction Service, Barcelona, Spain
[2]Fertibank, Assisted Reproduction Service, Barcelona, Spain

Study question: Frozen single blastocyst transfer in modified natural cycle (mNC) increases success rates reducing obstetric risks in egg recipients, compared to Hormone Replacement Therapy (HRT) protocols?

Summary answer: In egg recipients, single-blastocyst transfer in mNC showed higher pregnancy rates, lower miscarriage rates, higher new-born rates compared to HRT, being preterm birth rate comparable.

What is known already: When choosing endometrial preparation protocols for egg recipients, we must consider medication safety and costs, cycle's cancellation rate, clinical outcomes as maternal and fetal risks. The superiority of mNC over HRT for frozen embryo transfers (FET) has been reported in terms of delivery and miscarriage rates as well as obstetrical complications, but few data are available on egg recipients, being HRT protocols the routine treatment in most cases.

In donor programs, when a blastocyst freeze-all strategy or egg banking is applied, there is no longer need for donor-recipient synchronization and many FET could be performed in mNC cycles.

Study design, size, duration: Retrospective single-centre comparative clinical study, including 797 frozen single-blastocyst transfer (FSBT) initiated cycles between January 2020 and December 2021: 590 (74%) in HRT protocol and 207 (26%) in mNC protocol.

The two groups were homogeneous for donor's age (25,4 yo HRT Vs 25,8 yo mNC), recipient's age (42,1 yo HRT Vs 42,4 yo mNC), severe male factor (6% HRT Vs 4% mNC), and the need for a sperm donor (28% HRT Vs 22% mNC).

Participants/materials, setting, methods: Among 797 started cycles, we compared cancellation rates between HRT and mNC groups due to either medical reasons (inadequate endometrium, bleeding, ovulatory leak) or other issues (no embryo survival, flight cancellations, COVID-19 restrictions).

We studied the clinical outcomes of the 683 FSBT performed, comparing HRT and mNC cycles for pregnancy rate, clinical pregnancy rate, miscarriage rate, live birth rate, and preterm birth rate <35 weeks. We used Chi-square test to compare groups (p < 0,05).

Main results and the role of chance: CANCELLATION RATES: Out of the 797 endometrial preparation cycles started, the overall cancellation rate was 14% from which 72,8% due to medical reasons (inadequate endometrium, bleeding, ovulatory leak) and 27,2% due to other issues (no embryo survival, SARS-Cov-2 related issues, flight cancellations, etc.); when evaluating cancellation for medical reasons, we didn't find significant differences between HRT protocol cycles (9%) and mNC protocol cycles (7%), p = 0,33.

CLINICAL OUTCOMES: Out of the 683 frozen single blastocyst transfers performed, no twin pregnancies occurred as expected.

There were no statistically significant differences between HRT Vs mNC endometrial preparation protocol when comparing pregnancy rates (59% Vs 63%, p = 0,35), clinical pregnancy rates (49% Vs 57%, p = 0,10) and miscarriage rates (19% Vs 16%, p = 0,48). Live birth rate was significantly higher in the mNC (47%) compared to HRT (38%), p = 0,046.

Overall preterm birth rate <35 weeks was 3,9%, including <32 weeks 1,1% and <28 weeks 0,3%. There were no significant differences between HRT and mNC endometrial preparation protocol for preterm birth rate <35 weeks (3,6% Vs 4,6%, p = 0,75).

Limitations, reasons for caution: Single-centre retrospective comparative trial. Homogeneity studies included several confounding variables, but other bias could have been studied such as uterine factor, PGT-A rate or previous fertility treatments.

Wider implications of the findings: In donor programs, the use of modified natural cycle should be encouraged as first option irrespectively from recipient's age for FET in normo-ovulatory patients, considering the increased live birth rates when compared to HRT-FET cycles. Moreover, mNC cycles are more patient's friendly and cost-effective.

Abstract under embargo

definitive evidence exists regarding the optimal timing of transferring D6 blastocysts. Interestingly, a few studies have reported better reproductive outcomes if D6 blastocysts are transferred on the 5th day of progesterone administration instead of the 6th day of progesterone administration.

Study design, size, duration: This cohort study included a total of 718 vitrified D6 single blastocyst HRT-FET cycles performed between 2013 and 2022. 576 blastocysts were transferred on the 6th day of progesterone administration (2013-2021), and 142 blastocysts transferred on the 5th day of progesterone administration (2021-2022). Main outcomes were biochemical pregnancy rate (PR), implantation rate (IR), clinical pregnancy rate (CPR), and early pregnancy loss rate (EPLR).

Participants/materials, setting, methods: Patients undergoing HRT-FET in a public Fertility Clinic. Endometrial preparation included oral oestradiol (6mg/24hours), followed by vaginal micronized progesterone. As mentioned above, single blastocyst transfer was performed on either the 5th or 6th day of progesterone administration. Serum β-hCG level was measured 9-11 days after embryo transfer and biochemical pregnancy was defined as an hCG level >10IU/L. Clinical pregnancy was defined as visualization of a gestational sac and fetal heartbeat in gestational week 7.

Main results and the role of chance: In this cohort of a total of 718 HRT-FET cycles transferred on either the 5th or 6th day of progesterone administration the mean age of the patients at embryo transfer was 34.5 ± 4.5 years vs. 33.0 ± 4.9 years, respectively, p = 0.30. There was no significant difference between numbers of top-quality blastocyst transfers within the two groups 63% (89/142) vs. 64% (369/576), p = 0.76.

The overall, biochemical pregnancy rate (PR), implantation rate (IR), clinical pregnancy rate (CPR) and early pregnancy loss (EPLR) in the group of patients transferred on the 5th day of progesterone administration were 38% (54/142), 29% (41/142), 25% (36/142) and 33% (18/54). In the group of patients transferred on the 6th day of progesterone administration 41% (235/576), 33% (191/576), 30% (170/576) and 28% (65/235).

There were no significant differences between PR, IR, CPR and EPLR when transferring D6 vitrified blastocysts on either the 5th or the 6th day of progesterone administration (38% vs. 41%, p = 0.53, 29% vs. 33%, p = 0.33, 25% vs. 30%, p = 0.33 and 33% vs. 28%, p = 0.41).

Limitations, reasons for caution: Limitations of the study are the retrospective design and the limited number of D6 vitrified blastocysts transferred on the 5th day of progesterone administration. Furthermore, the two groups represented two different time periods.

Wider implications of the findings: Growing evidence shows that D5 vitrified blastocysts have better reproductive outcomes than slower developing embryos which are vitrified on day 6. Whether this is caused by intrinsic embryonic factors or poor timing of transfer in a subsequent FET cycle still needs to be unraveled.

Study question: Should blastocysts cryopreserved D6 be transferred on the 5th or 6th day of progesterone administration in HRT-FET cycles?

Summary answer: No significant differences in outcome parameters were found when D6 vitrified blastocysts were transferred on either day 5 or day 6 of progesterone in HRT-FET.

What is known already: Several studies have shown that D6 blastocyst transfer should be avoided in fresh transfer IVF cycles; consequently, these more slowly developing embryos are transferred in a HRT-FET cycle on the 6th day of progesterone administration in line with day 5 (D5) blastocysts. For successful implantation, a receptive endometrium and optimal synchronization between the endometrium and embryo are important. However, no

Study question: Is female age associated with worse outcomes following embryo transfer in either a natural cycle (NC) or artificial cycle (AC) in women receiving donated oocytes?

Summary answer: NC embryo transfers resulted in both lower miscarriage and higher livebirth rates, and the age of the female recipient did not modify this effect.

What is known already: Previous studies have demonstrated that NC may result in better outcomes than AC embryo transfer. When feasible, avoiding AC in advanced maternal age and/or couples using donated oocytes could be considered, given the potential compounding effect for certain negative maternal and perinatal outcomes such as gestational hypertension. However, there is limited research on the use of NCs in women of advanced maternal age and research thus far has shown that the luteal phase of the menstrual cycle in older women may be altered, thus potentially limiting the effectiveness of NC.

Study design, size, duration: This retrospective, multicentre, cohort study included all single blastocyst embryo transfers following oocyte donation performed between January 2010 and December 2019, subdivided according to the type of endometrial preparation performed (NC or AC). The oocyte donation model was preferred to minimize the potential confounding effect related to both poor embryo quality in older women and the influence that ovarian stimulation performed during autologous IVF may have on endometrial receptivity prior to a fresh embryo transfer.

Participants/materials, setting, methods: The main objective of the study was to compare livebirth delivery rates (LBR). The secondary outcomes included hCG positive pregnancy rate, clinical pregnancy rate (CPR) and miscarriage rate. Confounder-adjustment was performed using multivariable generalized estimating equations model regression analysis, adjusting for multiple confounders. Additionally, an interaction variable was added to the final multivariable model to assess whether female recipient age may modify the effect of each type of endometrial preparation on LBRs.

Main results and the role of chance: In total, 38259 embryo transfers were analysed, including AC (n = 34850) and NC (n = 3409). Mean recipient age was 42 years, with a range of 20-50 years. The results showed that despite being associated with a higher hCG positive pregnancy (57.1% vs 53.5%; OR 0.91 CI 0.84-0.98), AC were also associated with a higher miscarriage rate per hCG positive pregnancy (33.5% vs 27.9%; OR 0.70 CI 0.62-0.78) when compared to NC, resulting in slightly lower LBRs per transfer with AC (38.0% vs 38.6%; OR 1.13 CI 1.05-1.21). All primary and secondary outcomes were still significant following confounder adjustment. Confounder variables included were female donor and recipient age, recipient BMI, female factor infertility, male factor infertility, number of mature oocytes donated, oocyte status (fresh versus vitrified), sperm source (partner or donor), embryo status (fresh versus vitrified), embryo quality, endometrial thickness, and year of transfer. The interaction of endometrial preparation method with female recipient age was not statistically significant (aOR 1.02, 95% CI 0.99-1.05).

Limitations, reasons for caution: The retrospective nature of the study and the inherent risk of bias related to confounding may have impacted the results. Another limitation is the low numbers of natural cycles (9% of all cycles), which could be related to the low uptake to the treatment and/or to selection bias.

Wider implications of the findings: NC seems slightly better than AC and the differences between the two are unlikely to be modified by female age. Therefore, it seems reasonable to suggest NC for older women, as they would benefit from the decreased risk of miscarriage and hypertension during pregnancy.

O-026 A new mNC protocol that allows a 7-day window for FET planning

C. Alonso[1], G. Kohls[1], S. Caballero[1], S. Santos-Ribeiro[1], S. Soares[1], J.A. García Velasco[1]

[1]*IVIRMA, Reproductive Medicine, Madrid, Spain*

Study question: Is triggering necessary at 17 mm follicle diameter in a modified natural cycle (mNC), or does it allow flexible planning?

Summary answer: Embryo transfer can be scheduled when follicles measure 13 to 20 mm if endometrium is ready without impacting clinical outcome.

What is known already: Current practice is shifting, moving frozen embryo transfers (FET) from artificial cycles to natural cycles, which may complicate planning. The standard mean diameter to trigger in a mNC has classically been stablished in 17 mm, mimicking the size needed to obtain mature oocytes. Interestingly, research on triggering at different follicle sizes in a mNC has been limited. A previous study initiated progesterone based only on endometrial ultrasonographic characteristics and the presence of a dominant follicle of at least 12 mm and showed good results in ongoing pregnancy rates. However, it had a small sample size and rhCG was not administered.

Study design, size, duration: This is a multicenter, retrospective, observational study of 3,087 single frozen blastocyst transfers in mNCs carried out in 2,764 patients at our centers from January 2020 to September 2022.

Participants/materials, setting, methods: Selection criteria were the following: blastocyst on day 5/6 (minimum quality 3BB attending Gardner classification), regular menstrual cycles (26-35 days), normal uterine cavity assessed by ultrasound, serum progesterone <1.5 ng/mL and endometrial thickness ≥7 mm on the day of administration of rhCG, and absence of fluid in endometrial cavity. Triggering was done with a single dose of 250 µg sc rhCG, natural micronized progesterone 200mg bid was started two days later, then SET was performed.

Main results and the role of chance: Follicle size at time of triggering was stratified into three groups (13.0–15.9 mm; 16.0–18.9 mm; and ≥19.0 mm). No differences were seen regarding age, body mass index (BMI) and years of infertility, however, there were differences regarding egg donation (39.5%; 27.9%; and 27.4% respectively; p = 0.02) and the use of Preimplantational Genetic Testing for Aneuploidies (PGT-A) (19.4%; 34.01%; and 37.3%; p < 0.01). We found no differences in pregnancy rate (64.5%; 60.2%; and 57.4%; p = 0.19), clinical pregnancy rate (60.5%; 52.8%; and 50.6%; p = 0.10), implantation rate (62.10%; 52.9%; and 51.0%; p = 0.05) and miscarriage rate (15.0%; 22.2%; and 25.0%; p = 0.11), but differences were found in the ongoing pregnancy rate (OPR) (54.9%; 46.8%; and 43.1%; p = 0.02). however, those differences were not seen after adjusting for the use of PGT-A and egg donation: OPR at 16.0–18.9 mm vs 13.0–15.9 mm (aOR 2.37; 95% CI: 0.73–7.60; p = 0.15) and at 16.0–18.9 mm vs > 19mm (aOR 0.75; 95% CI: 0.54–1.05; p = 0.10).

Finally, OPR was assessed by follicle size by each millimeter from 13 mm (80,0%; 95% CI 29.9—99.0%) to 22 mm (54.6%; 95% CI 39.0—69.3%).

Limitations, reasons for caution: Follicle size at time of triggering 15 to 19 mm accounted for 84.7% of the mNCs included in this study, which leaves only a minority of cases in which triggering was done at "non conventional" follicle sizes. This results need to be confirmed by future prospective studies.

Wider implications of the findings: Our findings show that rhCG could be administrated from a follicle size of 13 to 22mm. Considering a follicular growth rate of 1-1.5mm per day, this approach could allow a flexibility of five to seven days, facilitating the planning of mNC FET in clinical practice.

[4]Université Catholique de Louvain, SRI Société de Recherche pour l'Infertilité, Brussels, Belgium
[5]Theramex, Medical affairs, London, United Kingdom
[6]Theramex, Medical affairs, Zurich, Switzerland

Study question: Does once-daily linzagolix for up to 6 months reduce the pain symptoms in women with endometriosis?

Summary answer: Once-daily oral use of the GnRH agonist linzagolix alone or in combination with combined hormonal add-back therapy (ABT) for 24 weeks improved endometriosis-associated pain symptoms.

What is known already: Linzagolix is an oral GnRH antagonist under development to treat endometriosis-associated pain (EAP). In the EDELWEISS 3 study linzagolix 200mg+ABT met its co-primary endpoints at 3 months by reducing dysmenorrhea (DYS) and non-menstrual pelvic pain (NMPP) in a clinically meaningful fashion along with a stable or decreased use of analgesics. Linzagolix 75mg significantly reduced DYS but not NMPP. Secondary endpoints were DYS, NMPP, overall pelvic pain, dyschezia, and dyspareunia at 6 months assessed with a numeric and/or verbal rating scale (NRS and/or VRS), and interference of pain with daily activities assessed with the Endometriosis-Health-Profile-30 (EHP-30) pain domain.

Study design, size, duration: EDELWEISS 3 was a randomized, double-blind, placebo-controlled Phase 3 study, investigating efficacy and safety of linzagolix 75mg and linzagolix 200mg with ABT (1mg estradiol/0.5mg norethindrone acetate) for up to 24 weeks in women with moderate to severe EAP. To qualify, subject had to demonstrate over 2 menstrual cycles at least moderate DYS and NMPP for $\geq$2 days each and at least moderate overall pelvic pain for $\geq$5 days.

Participants/materials, setting, methods: Eligible women with moderate to severe EAP were equally randomized to once daily oral: placebo, linzagolix 75mg or linzagolix 200mg+ABT. Efficacy assessments included DYS, NMPP, dyspareunia (assessed with a 4-point VRS), overall pelvic pain and dyschezia (assessed with an 11-point NRS), and interference of pain with daily activities (assessed with the EHP-30 pain domain). The co-primary endpoint was a responder analysis at Month 3. We present secondary endpoints at Month 6.

Main results and the role of chance: Participants (n = 484) had a mean age of 35 years, a BMI of 24kg/m^2 with 99% of subjects being White.

At Month 6, compared to placebo significant improvements in DYS and NMPP (VRS) were observed in the 200mg+ABT group, with an estimated mean change from baseline (CfB) of -1.83 (95%CI: 1.96, 1.70; difference with placebo $p < 0.001$) and 0.92 (95%CI: 1.03, 0.82; $p = 0.002$), respectively. For the 75mg group, the mean CfB was 1.10 (95%CI: 1.23; 0.97; $p < 0.001$) and 0.84 (95%CI: 0.95; 0.73; $p = 0.048$), respectively.

For overall pelvic pain (NRS), marked improvements were observed with an estimated mean CfB of 3.39 (95%CI: 3.74, 3.03; $p < 0.001$) for 200mg+ABT and 2.84 (95%CI: 3.20, 2.48; $p = 0.024$) for 75mg.

Similarly, dyschezia (NRS) was significantly improved for both groups with a mean CfB of 1.99 (95%CI: 2.29, 1.70; $p = 0.012$) for 200mg+ABT and -1.98 (95%CI: 2.28, 1.69; $p = 0.015$) for 75mg.

Both doses offered a marked, statistically significant improvement in the interference of pain with daily activities as measured on the EHP-30 Pain Dimension, with an estimated mean CfB of 35.60 (95%CI: 38.73, 32.48; $p < 0.001$) and -27.37 (95%CI: 30.50, 24.25; $p = 0.001$) for the 200mg+ABT and 75mg group, respectively.

Both doses did not provide significant improvements in dyspareunia.

Limitations, reasons for caution: We report data of the EDELWEISS 3 study for up to Month 6. An extension study of this trial will provide more information on the sustained effect and potential symptom recurrence after stopping treatment.

Wider implications of the findings: The linzagolix 200mg+ABT group provided substantial improvement in endometriosis-associated pain symptoms. The 75mg dose was less effective but demonstrated still marked improvements. There exists an substantial need for different treatment regimens in women suffering from endometriosis.

Trial registration number: NCT03992846

O-028 Genital tract infection and pelvic surgery contribute to the development of endometriosis

A.R. Han[1], S.K. Lee[2], J.C. Park[3], J. Han[2]

[1]CHA University, Fertility Center Daegu, Daegu, Korea- South
[2]Konyang University School of Medicine, Obstetrics and Gynecology, Daejeon, Korea- South
[3]Kyungpook National University School of Medicine, Obstetrics and Gynecology, Daegu, Korea- South

Study question: Was the incidence of endometriosis in women with a recent history of genital infection, pelvic surgery, or both increased?

Summary answer: The pelvic inflammation resulting from genital infection and pelvic surgical injury may play a role in developing endometriosis.

What is known already: Endometriosis is a multifactorial disease, and inflammation is considered a core pathology. Inflammation occurs due to pathogenic infection and tissue injury, and genital tract infection and surgical injury can be inducers for pelvic inflammation in endometriosis.

Study design, size, duration: A retrospective cohort study using the Korean National Health Insurance Service -National Sample Cohort 1 (KNHIS-SC I) from 2002-2013 (N = 1,025,340) was performed.

Participants/materials, setting, methods: 20- to 49-year-old women diagnosed with genital tract infections (GTI) or who underwent pelvic surgeries between 2002 and 2008 were collected and followed up for five years. A total of 30,336 women were diagnosed with GTI, 2,894 women underwent pelvic surgery, and 788 women with GTI and pelvic surgery were enrolled in each study. The comparison groups matched sociodemographic factors for each group were collected. The incidence of endometriosis in each group was analyzed.

Main results and the role of chance: The incidence of endometriosis per 1,000 person-year was 5.37, 5.17, and 20.81 in each case group and was significantly higher than in each comparison group. A recent history of GTI increased an adjusted hazard ratio (aHR) of 2.29 (1.99-2.63, 95% confidence interval) for the development of endometriosis. The aHRs of pelvic surgery history and the history of both GTI and pelvic surgery were 2.10 and 7.82, respectively.

Limitations, reasons for caution: The diagnosis and treatment codes registered on the NHIS data are used to claim HIRA NHI benefits, which may differ from the diagnosis or treatment performed in practice and it does not contain the used diagnostic method, disease severity, and the disease led to pelvic surgery were not specified.

Wider implications of the findings: Active treatment of genital infections and careful surgical procedures to minimize tissue injury may reduce the incidence of pelvic endometriosis.

[3]Second Department of Obstetrics and Gynecology Aretaieion Hospital, Medical School National and Kapodistrian University of Athens, Athens, Greece
[4]IVF Unit University Hospital of Larissa, Faculty of Medicine School of Health Sciences University of Thessaly, Larissa, Greece

Study question: Can non-coding RNAs (ncRNAs) serve as sensitive biomarkers to differentially diagnose endometriosis accurately and precisely?

Summary answer: Non-coding RNAs appear to be promising biomarkers for endometriosis diagnosis, providing adequate diagnostic efficiency, especially when co-evaluated as a model and not as single markers.

What is known already: Endometriosis is a chronic, inflammatory gynecological disease characterized by endometrial-like tissue development outside the uterus. This benign, estrogen-dependent inflammatory disorder affects 6–10% of women of reproductive age and over 40% of patients with endometriosis present with infertility. Despite advances, endometriosis diagnosis remains challenging, and it is mainly relied upon surgical assessment, commonly via laparoscopy. The invasive nature of endometriosis diagnosis could be avoided if sensitive biomarkers for endometriosis deferential diagnosis were available. In the context of developing non-invasive diagnostic methods, the role of ncRNAs has been investigated and this study aims to collectively synthesize and critically analyze existing evidence.

Study design, size, duration: A systematic review was performed in PubMed/Medline and Embase up to April 2022 followed by a meta-analysis. Original, full-text articles in English comparing the diagnostic validity of ncRNAs versus conventional methods for endometriosis diagnosis were included. Study inclusion requirements were the following: presenting detailed information regarding the tissue where ncRNAs were isolated, methods employed for ncRNA detection, and finally inclusion of data on ncRNA diagnostic efficiency, namely sensitivity, specificity, and area under the curve (AUC).

Participants/materials, setting, methods: The studied population consisted of women with endometriosis confirmed via conventional diagnostic methods, including laparoscopy and histology. The control group consisted of women without endometriosis. Data indicating ncRNA diagnostic efficiency, including sensitivity, specificity, and AUC were extracted. Following extraction, data were meta-analyzed employing univariate analysis with Clopper-Pearson. Confidence intervals were calculated employing the random-effects model. Bivariate analysis to plot the summary receiver operating characteristic (SROC) curve was also employed. R Programming Language was used.

Main results and the role of chance: Twenty-six studies were included and 64 ncRNAs were analyzed. Included studies were categorized into two groups. In the first group the diagnostic efficiency of single ncRNAs was evaluated. In the second group the diagnostic efficiency of models comprising of two or more ncRNAs was assessed. Considering the first group, two ncRNAs, namely miR-200c and miR-199a, differentially diagnosed endometriosis with an AUC of 1.000. Meta-analysis revealed that the total diagnostic efficiency of single ncRNAs is characterized by an AUC of 0.783, sensitivity 78.0% (95%CI:72.3-82.8%), specificity 73.8% (95%CI:67.8-79.1%), Positive Predictive Value (PPV) 81.1% (95%CI:77.1–84.5%), and Negative Predictive Value (NPV) 69.5% (95%CI:62.4–75.9%). Sensitivity analysis presenting the total diagnostic efficiency of single ncRNAs evaluated from two or more individual studies was performed. The total AUC was reported to be 0.824, sensitivity 81.8% (95%CI:72.0–88.7%), specificity 80.0% (95%CI:68.8-87.9%), PPV 87.6% (95%CI:80.3–92.4%), and NPV 72.2% (95%CI:57.4–83.3%). Regarding the second group, the ncRNA model comprised of miR-125b-5p, miR-451a and miR-3613-5p reporting the highest diagnostic efficiency, with an AUC of 1.000. Meta-analysis revealed that the total diagnostic efficiency of ncRNA models is characterized by an AUC of 0.896, sensitivity 86.8% (95%CI:81.9–90.5%), specificity 80.3% (95%CI:68.9-88.2%), PPV 88.3% (95%CI:82.2–92.5%), and NPV 78.0% (95%CI:68.2–85.4%).

Limitations, reasons for caution: The main limitation is the high heterogeneity observed among most of the studied outcomes. This is mainly attributed to the fact that the number of the participants significantly ranged between the studies. Another reason for caution is the high heterogeneity observed regarding the methods employed for ncRNA profiling and validation.

Wider implications of the findings: Data presented herein indicate that ncRNAs appear as highly promising non-invasive biomarkers for endometriosis diagnosis, especially when two or more ncRNAs are co-evaluated as a model. Larger scale studies should focus on developing artificial intelligence based diagnostic algorithms incorporating ncRNAs profiling coupled by molecular, biochemical, and imaging diagnostic data.

Trial registration number: Not applicable

Study question: Do gut microbial composition and functionality differ between women with and without endometriosis?

Summary answer: Gut microbiome diversity and composition (species and microbial pathways) were not significantly different between women with and without endometriosis.

What is known already: Endometriosis, defined as the presence of endometrial-like tissue outside of the uterus, is one of the most common female reproductive disorders. Although different theories of the possible causes of endometriosis have been proposed, its pathogenesis is not clear. Novel studies indicate that the gut microbiome may be involved in the etiology of endometriosis, nevertheless, the connection between microbes, its dysbiosis and the development of endometriosis remains unexplored. This study aims to analyze and compare the gut microbiome profile in women with and without endometriosis in a large cohort to identify microbial targets potentially involved in the development of the disease.

Study design, size, duration: This case-control study included a subsample of 1000 women (age = 45.61 ± 10.36 years; BMI = 25.67 ± 5.59) of the Estonian Microbiome (EstMB) cohort, a volunteer-based sub-cohort of the Estonian Biobank created in 2017. 136 women with endometriosis and 864 control women who have not been diagnosed with endometriosis or any of its most prevalent comorbidities (systemic lupus erythematosus, rheumatoid arthritis, autoimmune thyroiditis, celiac disease, multiple sclerosis and irritable bowel syndrome) were included in this study.

Participants/materials, setting, methods: Microbial DNA from fecal samples was extracted and sequenced by paired-end metagenomic shotgun sequencing (Illumina Novaseq 6000 platform). Microbial functional pathways were annotated using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database (https://www.genome.jp/kegg/). Partitioning around medoids (PAM) algorithm was performed to cluster the microbial profile of the Estonian population. The alpha- and beta-diversity and differential abundance analyses were performed to assess the gut microbiome (species and KEGG orthologies [KO]) in both groups.

Main results and the role of chance: After metagenomics analysis, 17180 microbes and 7869 KO were detected. Those bacteria and KO with a relative abundance > 1 % were used for the diversity and differential abundance analyses, resulting in 2442 species and 1974 KO. PAM clustering analysis stratified the study population into two enterotypes: one characterized by a high abundance of *Prevotella copri* and the second presented a high abundance of *Bacteroides* genus (PERMANOVA, p = 0.001). However, the enterotypes were not associated with the presence/absence of endometriosis. Microbial alpha-diversity (observed richness and Shannon's index) was not significantly different between women with and without endometriosis (all p-value > 0.05). Beta-diversity analyses on the microbial and functional profile (species and KO profile) indicated no significant dissimilarity between groups

(PERMANOVA, all $p > 0.05$). No differential species nor KO were detected after multiple testing adjustment (all FDR $p > 0.05$).

Limitations, reasons for caution: This case-control study did not identify a distinct gut microbial profile in women with endometriosis. A deeper analysis considering potential confounders (specifically hormonal treatment in patients) is needed to further confirm our results.

Wider implications of the findings: Endometriosis is a widespread disorder affecting ~10% of reproductive-age women. To the best of our knowledge, this is the biggest metagenome study performed in women with endometriosis. Our findings do not find enough evidence to support the existence of a gut microbiome-dependent mechanism implicated in the pathogenesis of endometriosis.

O-031 The natural history of endometriosis in pregnancy: An ultrasound study of the morphological features of deep endometriosis (DE) and ovarian endometrioma

E. Bean[1], J. Knez[2], T. Setty[1], A. Tetteh[1], D. Casagrandi[1], D. Jurkovic[1]

[1]*University College London Hospital, Women's Health, London, United Kingdom*
[2]*University Medical Centre Maribor, Clinic for Gynecology, Maribor, Slovenia*

Study question: What is the impact of pregnancy on the morphological features and behaviour of ovarian endometrioma and deep endometriotic nodules?

Summary answer: For the majority of women, despite features of decidualization being common in the first and second trimesters, endometrioma and deep nodules will regress during pregnancy.

What is known already: Deep endometriosis and endometrioma subtypes are thought to affect approximately 5% of women in pregnancy, with about 50% being unaware of their condition. Pregnancy has a major effect on the size and morphological features of endometrioma, with published studies reporting a tendency for cyst regression. Decidualization, a hormonally induced pregnancy-related phenomenon, effects endometriomas and may raise suspicion of an ovarian malignancy. The behaviour of deep endometriosis in pregnancy is poorly understood and there is limited available literature on the subject.

Study design, size, duration: This was a prospective observational cohort study conducted over three years at a single centre. We included 65 women with a viable eutopic pregnancy and concomitant ultrasound features of deep and/or ovarian endometriosis. The study was conducted at University College London Hospital, which is a tertiary level referral unit for early pregnancy complications and an accredited Endometriosis Centre.

Participants/materials, setting, methods: All women who participated provided written consent and were invited for surveillance ultrasound examinations at the time of their routine scans in pregnancy. All scans were performed by a single operator to minimise interobserver error. The change in size of endometrioma and nodules were reported as change in their mean diameter. Endometrioma with irregular thick inner walls, hyperechoic papillary projections and/or high vascularity and hyperechoic nodules with moderate to high vascularity were reported as decidualized.

Main results and the role of chance: Sixty five women were included in the study. Their median age was 34 years (23-44), and the gestation at presentation was 7 + 6 weeks (3 + 6 to 18 + 0). 47/65(72%) were nulliparous, 48/65(74%) had a background of endometriosis and 19/65(29%) conceived following IVF. There were 10/65(15%, 95%CI 7-24) women with endometrioma alone, 28/65(43%, 95%CI 31-55) with nodules alone and the remaining 27/65(42%, 95%CI 30-54) had both.

29/34(85%, 95%CI 73-97) women with endometrioma experienced cyst regression, 2/34(6%, 95%CI 0-14) experienced cyst growth and in 10/34(29%, 95%CI 14-45) there was complete resolution of all cysts. 43/51(84%, 95%CI 74-94) women with nodules experienced nodule regression, 2/51(4%, 95%CI 0-9) experienced nodule growth and in 4/51(8%, 95%CI 0-15) there was complete resolution of all nodules. 5/37(14%, 95%CI 3-25) women who attended postnatal follow-up, experienced complete resolution of all endometriotic lesions during pregnancy .

In 10/34(29%, 95%CI 14-45) women with endometrioma and 27/51(53%, 95%CI 39-67) with nodules, a pattern of growth was observed in the first and second trimesters, which preceded regression in later pregnancy.

Features of decidualization were observed in 17/34(50%, 95%CI 33-67) women with endometrioma, most commonly in the 1st trimester, and 25/51(49%, 95%CI 35-63) women with nodules, most commonly observed in the 2nd trimester.

Limitations, reasons for caution: The lack of extended follow-up fails to establish the long-term impact of pregnancy, lactation and postnatal contraception on the behaviour of endometriosis. This study relies on ultrasound alone for the detection of moderate/severe disease with no correlation with laparoscopy.

Wider implications of the findings: Sonographic changes of endometriosis in pregnancy are difficult to differentiate from characteristics of malignant lesions. Better understanding of the appearance of endometriosis in pregnancy is vital to reduce unnecessary surgical procedures, associated morbidity to mothers and babies and will help clinicians to counsel women regarding the significance of their condition.

Trial registration number: The study was registered on Research Registry (Unique identifying number: researchregistry4569).

Study question: To assess the effect of oral relugolix combination therapy (Relugolix-CT) in the subgroup of women with endometriosis-associated pain who received prior first-line hormonal treatment.

Summary answer: Relugolix-CT significantly reduced dysmenorrhoea and non-menstrual pelvic pain (NMPP) through 24 weeks in women with endometriosis-associated pain who received prior first-line hormonal treatment.

What is known already: ESHRE recommends hormonal contraceptives or progestogens as first-line therapy for endometriosis; however, these treatments may not be efficacious for all women. SPIRIT 1&2 were Phase 3, replicate, randomised studies of oral Relugolix-CT (relugolix 40 mg, estradiol 1 mg, norethisterone acetate 0.5 mg) in premenopausal women (aged 18–50 years) with moderate-to-severe endometriosis-associated pain. In SPIRIT 1&2, Relugolix-CT significantly improved dysmenorrhoea, NMPP and daily functioning (measured by the Endometriosis Health Profile-30 pain domain score) compared with placebo over 24 weeks. Relugolix-CT was well-tolerated and bone mineral density showed a minimal decline (<1%) from baseline to Week 24.

Study design, size, duration: At screening, women were required to have at least moderate menstrual and non-menstrual pain during their last cycle. In total, 1261 women with diagnosed endometriosis and moderate-to-severe dysmenorrhoea and NMPP at baseline were randomised 1:1:1 to receive once-daily Relugolix-CT or placebo for 24 weeks, or delayed Relugolix-CT (relugolix 40 mg then Relugolix-CT; 12 weeks each). Study candidates who received hormonal treatment for endometriosis completed a washout period prior to the screening and run-in period.

Participants/materials, setting, methods: Analyses were performed using pooled SPIRIT 1&2 data in women previously receiving first-line hormonal treatment (e.g. oral contraceptives and/or progestogens; N = 392). Co-primary endpoints: proportion of dysmenorrhoea and NMPP responders at Week 24. Responders were women achieving a predefined, clinically meaningful reduction from baseline in daily Numerical Rating Scale (NRS [0=no pain, 10=worst pain imaginable]) score and no increase in analgesic use. Least squares (LS) mean changes in NRS scores were assessed by a mixed-effects model.

Main results and the role of chance: In total, 121 women in the Relugolix-CT group and 134 in the placebo group had received prior first-line hormonal treatment, of which combined oral contraceptives and/or dienogest were the most common medications. Data for the delayed Relugolix-CT group were used for safety assessment only and are not reported here. Baseline demographics and clinical characteristics were comparable between the subgroup of women who received prior first-line hormonal treatment and the overall study population.

In this subgroup, the proportion of dysmenorrhoea responders with Relugolix-CT vs placebo at Week 24 was 70.2% vs 27.6%, respectively ($p < 0.0001$); the proportion of NMPP responders was 60.3% vs 40.3%, respectively ($p = 0.0013$).

In the Relugolix-CT group, LS mean NRS scores for dysmenorrhoea decreased from 7.2 (severe) at baseline to 1.7 (mild) at Week 24, with a significant change from baseline vs placebo ($p < 0.0001$). LS mean NRS scores for NMPP decreased from 5.6 (moderate) at baseline to 2.8 (mild) at Week 24 with Relugolix-CT, with a significant change from baseline vs placebo ($p = 0.0097$).

The proportion of women who were analgesic-free at baseline was 7.4% with Relugolix-CT and 3.7% with placebo; this increased to 48.8% with Relugolix-CT and 18.7% with placebo at Week 24 ($p < 0.0001$).

Limitations, reasons for caution: Assessment of endometriosis-associated pain at screening visit was done after the wash-out period; therefore, data for endometriosis symptoms experienced by women while receiving hormonal treatment prior to study entry, as well as the duration of the previous treatments, were not available.

Wider implications of the findings: Relugolix-CT significantly reduced dysmenorrhoea and NMPP, vs placebo, through 24 weeks in women with endometriosis-associated pain who received prior first-line hormonal treatment. The proportion of women in this subgroup who were analgesic-free increased through 24 weeks with Relugolix-CT. Results were comparable to the overall SPIRIT 1&2 population.

[8]University of Edinburgh, MRC Centre for Reproductive Health- Queens Medical Research Institute, Edinburgh, United Kingdom

Study question: Does a Decision-Aid for those considering elective egg-freezing impact decisional conflict, the decision-making process, and quality of the decision made, compared to existing information?

Summary answer: The Decision-Aid significantly reduced decisional conflict and improved preparedness for decision-making.

What is known already: Elective egg-freezing offers women the potential to extend their reproductive years. The decision to freeze eggs is complex, and our previous data shows that 78% of women had high decisional conflict (uncertainty) when they considered elective egg-freezing. Decision-Aids are the gold-standard for supporting complex health-related decisions. They have been shown to reduce decisional conflict and improve knowledge, risk perception, and decision alignment with personal values, when compared to standard care alone across a range of health conditions. We developed an online Decision-Aid to support women considering elective egg-freezing.

Study design, size, duration: A single-blinded, two-arm parallel group Randomised Control Trial. Participants were recruited September 2020-March 2021 (target n = 286). Randomisation was 1:1 to the intervention (Decision-Aid plus existing information) or control (existing information only) group, stratified by Australian state/territory and prior consultation with an IVF specialist about elective egg-freezing. Existing information was the Victorian Assisted Reproductive Treatment Authority website. Online surveys were completed at recruitment (baseline), 6, and 12-months.

Participants/materials, setting, methods: Australian women aged ≥18 years, considering elective egg-freezing, proficient in English, and with internet access were recruited using various methods including social media, Google advertising, newsletters, and clinic referrals. Participants completing the baseline survey were randomised (intervention n = 150, control n = 156) and emailed their allocated resources. Subsequent surveys were emailed 6 and 12-months post-randomisation. Surveys covered decisional conflict (primary outcome), distress, egg-freezing and fertility knowledge, decision made/not made, preparedness for decision-making, informed choice, and decisional regret.

Main results and the role of chance: Of 306 participants (mean age=30 years, SD: 5.2), 50% were single and 65% worked in professional occupations. At 6-months, the intervention group was substantially more prepared for decision-making than the control (Preparation for Decision-Making Scale; mean score difference: 9.22 [95% CI: 2.35, 16.08], $p = 0.009$). Overall, 77% of participants completed the primary outcome at 12-months (intervention n = 113, control n = 124). Between baseline and 12-months, the mean reduction in Decisional Conflict Scale (DCS) scores was greater for the intervention group than the control (mean score difference: -6.99 [95% CI: -12.96, -1.02], $p = 0.022$), whilst there were no group differences in distress (Depression Anxiety and Stress Scale; mean score difference: 0.61 [95% CI: -3.72, 4.93], $p = 0.783$), knowledge (study-specific scale; mean score difference: 0.23 [95% CI: -0.21, 0.66], $p = 0.309$) and whether a decision had been made about egg-freezing (odds ratio: 1.95 (95% CI: 0.67, 5.69), $p = 0.221$). No differences were observed between groups in informed choice (Multi-Dimensional Measure of Informed Choice; relative risk: 1.00 [95% CI: 0.81, 1.25]) or decision regret (Decisional Regret Scale; median score difference: -5.00 [95% CI: -15.30, 5.30]) for participants who had made their decision about egg-freezing at 12-months (intervention n = 48, control n = 45).

Limitations, reasons for caution: The total eligible population reached cannot be calculated due to the broad recruitment methods used. Adaption of some scales to improve relevancy may impact validity. Biases from self-selection and the use of self-reported data are possible, and some results had small sample sizes limiting the inferences made.

Wider implications of the findings: This is the first study to evaluate the effectiveness of a Decision-Aid for women considering elective egg-freezing. It demonstrates the benefit of a Decision-Aid in supporting women's decision-

making. Given these results, the Decision-Aid will be made publicly available. There is also potential to adapt the tool for international relevancy.

O-034 Staff and patient evaluation of fertility staff performance during sharing bad news conversations.

S. Gameiro[1], E. Adcock[2], C. Graterol Munoz[1], A. D'Angelo[2], J. Boivin[1]

[1]*Cardiff University, School of Psychology, Cardiff, United Kingdom*
[2]*Cardiff University, School of Medicine, Cardiff, United Kingdom*

Study question: What are fertility staff and patients' evaluation of staff performance during sharing bad news (SBN) conversations?

Summary answer: In positive SBN conversations, staff and patient ratings of staff performance are similarly good, but in negative SBN conversations patients' ratings are lower than staff's.

What is known already: Bad news, defined as news that negatively alters patients' view of their future, happens at all stages of fertility care. Fertility staff perceive SBN among the biggest challenges of their job. 47% of patients express staff could improve bad news delivery. SPIKES is an evidence-based protocol that has shown promise in guiding SBN in fertility care via breaking the task in six steps: Setting the scene, evaluating patients' Perception, getting patients Invitation, sharing Knowledge, addressing Emotions, and Summarizing and planning future care. Knowledge about how staff perform during SBN conversations and which factors are associated with performance is lacking.

Study design, size, duration: Two cross-sectional mixed-methods online surveys were distributed to staff (via ESHRE) and patients (via charities, social media). Inclusion criteria for staff were working at a fertility clinic and SBN at least once a month and for patients being 18 years of age and having had a SBN conversation with staff in past two months. 334 staff and 345 patients clicked survey links, of which 217 staff and 222 patients completed it (65% and 64% completion).

Participants/materials, setting, methods: Dependent variable was staff SBN performance across SPIKES steps, measured with CARE (empathy) and the Breaking Bad News Assessment Schedule (other steps). Independent variables were actor (staff, patient) and overall evaluation of the SBN conversation (positive, negative). Factors assessed related to staff and patients' background (e.g., gender, age), fertility care context (e.g., patients: parental status, treatment stage, staff: role, burnout, time pressure, SBN training), and SBN conversation (e.g., patients: person vs remotely, alone vs accompanied).

Main results and the role of chance: Crosstabs of actor and evaluation showed a higher proportion of staff (85%) than patients (67%) evaluated the SBN conversation as positive ($X^2(1) = 38.863, P<.001$).

MANOVA investigating differences in staff's SBN performance according to actor and overall evaluation revealed significant effects of actor (Hotelling's Trace $T = .236, F(388,6) = 15.279, p<.001, \eta^2_p = .191$), overall evaluation ($T = .344, F(388,6) = 22.233, p<.001, \eta^2_p = .256$), and their interaction ($T = .127, F(388,6) = 8.243, p<.001, \eta^2_p = .113$). Follow-up ANOVAs showed the same pattern for all SPIKES steps: in positive SBN staff and patient ratings of staff performance were similar (~4 from 1 = poor/not at all to 5 = excellent/completely), but in negative SBN patients' ratings were lower than staff's (~2.5 vs 4, η^2_p ranged .160[Setting] to .289[Perception]).

Among staff, physicians and nurses tended to rate their SBN performance better than embryologists across all SPIKES steps except Knowledge and Emotions (β ranged .166[Invitation] to .312[Perception]). Reporting ≥1 burnout symptom was associated with worse performance in Emotions ($\beta = -.168, P = .049$), time pressure was associated with worse performance in Perception ($\beta = -.185, P = .019$), and having attended SBN training with better performance in Setting ($\beta = .295, P<.001$).

Patients who were alone during the SBN conversation rated staff SBN performance worse than patients who were accompanied in all SPIKES steps (β from -.154[Summary] to -.403[Setting]). Patients with children rated staff performance in Setting ($\beta = .156, P = .015$), Emotions ($\beta = .158, p = .031$), and Summary ($\beta = .142, p = .048$) better than childless patients.

Limitations, reasons for caution: Online data collection attracted mostly UK patients while staff were from all over the world. SBN performance was reported and not based on behavioral observation, though based on sound questionnaires that evaluate different aspects of performance.

Wider implications of the findings: Staff and patients agree about what good SBN conversations are, but patients are more critical of bad SBN conversations. Staff SBN performance seems more a function of the context in which news are shared than of actors' background. SBN training can support staff recognizing bad SBN conversations and improving performance.

O-035 Research-informed educational materials to promote the routine implementation of psychosocial care for unsuccessful fertility treatment (PCUFT) at clinics: healthcare professionals' and patients' views

M. Sousa Leite[1,2,3], S. Gameiro[1]

[1]*Cardiff University, School of Psychology, Cardiff, United Kingdom*
[2]*Institute of Public Health of the University of Porto ISPUP, Epidemiology Research Unit, Porto, Portugal*
[3]*Laboratory for Integrative and Translational Research in Population Health ITR, Perinatal and Pediatric Mental Health, Porto, Portugal*

Study question: Are educational materials to promote the routine implementation of PCUFT at clinics acceptable and feasible for healthcare professionals (HCPs) and patients?

Summary answer: HCPs and patients expressed high demand for PCUFT and welcomed educational materials to support this endeavour but expressed different views about how to offer it.

What is known already: Nine in ten patients want to discuss the possibility of fertility treatment being unsuccessful as part of routine care offered at clinics, but only 35% of patients report having this opportunity. Offering PCUFT, defined as assistance and guidance on the implications of treatment being unsuccessful, could promote patients' positive adjustment to this loss. However, it is unknown if and how PCUFT varies across countries and HCPs' and patients' perceived barriers towards its implementation. The present international qualitative study investigated HCPs' and patients' willingness and preferences about using research-informed educational materials to support the implementation of PCUFT at fertility clinics.

Study design, size, duration: Seven Focus Groups were conducted with HCPs (March 2022) from Europe (Belgium/Finland/Germany/Italy/Portugal/Spain/UK) and South America (Argentina/Brazil/Chile), and patients and patient advocates (March-December 2022) also from Europe (UK/Portugal) and South America (Argentina/Chile). Participants were invited to participate through fertility charities/associations and social media. Eligibility criteria were being aged 18 or older, working at a fertility clinic (HCPs) or charity (advocates), or waiting to initiate or undergoing fertility treatment or having completed treatment within six months (patients).

Participants/materials, setting, methods: Semi-structured script following Bowen's (2009) framework. Section one evaluated demand and acceptability of implementing PCUFT. Section two introduced a proposal of research-informed educational materials to promote PCUFT (*MyJourney* webpages - for HCPs: practical advice on introducing PCUFT and addressing patients' FAQs; for patients: information and support for unsuccessful treatment in video, text, FAQs). Questions elicited views on the materials' acceptability, practicality and adaptation. Focus groups were recorded, transcribed verbatim, and data analysed with Framework Analysis.

Main results and the role of chance: Thirty-four patients, seven advocates, 15 HCPs participated. Patients were 38 years old and trying to conceive for around three years, most were female(91.18%) and childless(73.53%). HCPs were mostly psychologists(40.00%) or physicians(33.33%) in the field for around 22 years. Framework analysis generated four themes and one meta-theme, reflecting a need for a normative shift towards having PCUFT as part of routine care. Themes were: (1) need for better collaboration and support, strongly endorsed by patients, who perceived PCUFT

would enable them to better cope with treatment, make more long-term informed-decisions, and feel supported, particularly after treatment; (2) current PCUFT approaches are almost non-existent/non-optimal. Patients and HCPs agreed PCUFT is not offered but expressed different views about its appropriateness. HCPs considered PCUFT more appropriate at later treatment stages and expressed lack resources and know-how to implement it; (3) PCUFT requires an empathic, hopeful, multidisciplinary approach. While patients want to receive in-depth medical advice about their full treatment options, potential outcomes and support to prepare for (unsuccessful) treatment, most HCPs envisioned present-focused information-sharing and support tailored to patients' treatment stage; and (4) high demand for educational materials to promote PUCFT. *MyJourney* package prototype is beneficial but needs improvements to be acceptable and feasible.

Limitations, reasons for caution: Non-probability sample. Although the patients' sample was heterogeneous (including heterosexual and homosexual couples; from private and public clinics), patients were primarily white, well-educated, employed, and childless women, limiting the generalisation of results and comparisons across gender.

Wider implications of the findings: HCPs and patients agree PCUFT is needed and beneficial, but HCPs' will need reassurance about the right timing and support on appropriate ways to implement it given its sensitivity and perceived potential adverse effects. Educational materials, including the *MyJourney* package, are seen as added value to promote a cultural shift.

O-036 Are male infertility patients and male partners to infertility patients impacted differently by fertility challenges?

J. Boivin[1], M. Markert[2], E. Roitmann[3], A. Domar[4]

[1]*Cardiff University, Cardiff Fertility Studies Research Group School of Psychology-, Cardiff, United Kingdom*
[2]*Ferring Pharmaceuticals A/S, Health Economics & Outcomes Research, Copenhagen, Denmark*
[3]*Roitmann Digsmed SASU-, Roitmann Digsmed SASU-, Paris, France*
[4]*Harvard Medical School, Obstetrics- Gynecology- and Reproductive Biology., Houston, U.S.A.*

Study question: How do male infertility patients and male partners to infertility patients differ on the impact of diagnosis on their daily lives, relationships and mental health?

Summary answer: Significantly more male patients than male partners agreed that diagnosis impacted their activities of daily living, partner relationships and mental health.

What is known already: Globally, male factor infertility is causal (solely or with other factors) in approximately 50% of infertility cases[1]. The male patient perspective on infertility remains under-researched as is that of the male partner to the infertile patient. A recent James Lind Alliance priority setting study, including health professionals, patients and health care providers, identified psychological aspects of male infertility as one of the top 10 research priorities within male infertility[2]. Previous literature has documented that men with male factor infertility can experience significant mental distress compared to other diagnoses. However, there is a paucity of evidence about other aspects of life.

Study design, size, duration: This is a secondary analysis of the male subpopulation of the international, online, 30-minute, quantitative '1000 dreams' survey, which collected data from March to May 2019 among 1944 respondents. The male subpopulation consisted of 847 respondents from nine countries (United States [US], United Kingdom [UK], Germany, Spain, Italy, France, China, Australia, and Canada). Male respondents had either been diagnosed with infertility (patients) or had a partner who had received a diagnosis of infertility (partners).

Participants/materials, setting, methods: Infertile patients (n = 351) and partners (n = 496) were at different stages of the treatment journey (diagnosis, treatment). Average age at time of questionnaire completion was 36.33 years (SD = 10.06). Survey topics covered impact on mental health, relationships and daily activities. Respondents indicated their extent of agreement with each statement on a scale from 1 to 7 (do not agree at all–completely agree). Response categories 5-7 (somewhat to fully agree) were combined. Chi-square comparison tests were used.

Main results and the role of chance: Significantly more male patients (57%, n = 351) than male partners (40%, n = 496) agreed with some impact of their diagnosis on their activities of daily living ($p < 0.001$). Of those reporting *any* impact, male patients were significantly more likely to agree that they withdraw from social engagements than male partners (55% vs 38%, $p < 0.001$). A significantly greater proportion of male patients agreed that the diagnosis had a negative impact on their work-life balance compared with male partners (58% vs 42%, $p < 0.001$) and a negative impact on their career progression (51% vs 36%, $p < 0.001$). Similarly, 60% of male patients and 52% of male partners agreed that there were some impacts on their relationship with their partners ($p = 0.03$). Of these, more male patients than male partners somewhat or fully agreed that the financial commitment began to put a strain on their partner relationship (54% vs 43%, $p < 0.01$). Among male patients (n = 351), 62% felt that their diagnosis had an impact on their mental health, and of these, 30% sought professional support services. Among male partners (n = 496) 47% reported an impact of their partners diagnosis on their mental health and of these 23% sought professional support services (all differences were NS).

Limitations, reasons for caution: This survey is based on an anonymous, self-reported online survey with no opportunities to validate data by health care professionals and respondents were not able to ask clarifying questions. There is a risk that the data is not fully representative of the male patient/partner population.

Wider implications of the findings: The presence of a male factor diagnosis impacts the emotional experience of infertility on males. It highlights the importance of recognizing that while infertility is a couple diagnosis, men may have varying needs for support depending on whether the source of fertility problems is male.

O-037 Sex and reproductive health education in the UK: What are we teaching teenagers?

R. Biswakarma[1], K. Maslowski[2], M. Reiss[3], J. Harper[2]

[1]*University College London, Institute for Education, London, United Kingdom*
[2]*University College London, Institute for Women's Health, London, United Kingdom*
[3]*University College London, Institute of Education, London, United Kingdom*

Study question: Are we giving teenagers in the UK a comprehensive sex and reproductive health education?

Summary answer: Teenagers report learning about how not to get pregnant but have little education in other reproductive health topics.

What is known already: Both the World Health Organization (WHO) and the United Nations Educational, Scientific and Cultural Organization (UNESCO) agree that sex education is a necessary component of education. But globally most countries teach limited information on sex education, concentrating on how not to get pregnant. They may cover puberty, contraception and sexually transmitted infections (STIs) but rarely teach how to get pregnant, PCOS, endometriosis or menopause. We have analysed the UK curriculum at the two exam stages (age 16 and 18), which has shown that the majority of topics that come under reproductive health education are not covered.

Study design, size, duration: We conducted a mixed-methods study, distributing an anonymous, online survey using multiple choice and open-ended questions on Qualtrics software to schools for students aged 16-18 years. The schools distributed the survey either in the classroom or the link was given to the students. The survey was live for 62 weeks (10th May 2021 – 18th July 2022). The final sample size was n = 1224.

Participants/materials, setting, methods: The study had ethical approval from UCL research Ethics Committee ID no: 9831/006. A total of 1244 students completed or partially completed the survey: 754 girls, 344 boys, 38 others, 17 prefer not to say. The qualitative data was analysed thematically.

Main results and the role of chance: Over half of the teenagers' rated the sex education they received in their schools' to be adequate or below (55%, 708/1080). The top three most popular topics taught in schools was contraception (90%, 968/1080), STI's (85%, 914/1080) and puberty (83%, 899/1080). Outside of schools the most popular topics learnt by teenagers were abortion (63%, 675/1080), puberty (60%, 648/1080) and the menstrual cycle (60%, 650/1080). The majority learnt about reproductive health topics through the internet (69%, 745/1080) and social media (60%, 646/1080) and over half (74%, 800/1076) of these teenagers do not or only sometimes, talk to their parents/guardian about reproductive health topics. Common reason for not talking to their parents/guardian was because it was uncomfortable or embarrassing (46%, 386/842).

Half of the teenagers (49%, 502/1024) did not know when a woman is most fertility during their menstrual cycle. Teenagers estimated the oldest age women can naturally have children as: 40 years old (10%, 104/1024), 45 years old (23%, 263/1024), 50 years old (21%, 214/1024), and the oldest age a man can naturally have children: 60 years old (12%, 122/1024), 70 years old (12%, 122/1024), 80+ years old (36%, 366/1024). Teenagers showed better knowledge of female fertility than of male fertility.

Limitations, reasons for caution: Only 20 schools participated so the study results are not representative of all UK schools. Personal contacts and a teacher forum were used for survey promotion. Schools in more deprived areas, faith schools and teens without internet access and a digital device did not participate in the survey.

Wider implications of the findings: Schools should be teaching all aspects of reproductive health. The data from this study, and school talks given by the second author has helped the development of a free teachers' reproductive health education PowerPoints and guide which is being promoted by the ESHRE International Fertility Education.

Abstract citation ID: dead093.038
O-038 Is a 10-year retention period sufficient after elective oocyte vitrification (EOV)?

J. Nekkebroeck[1], L. Leunens[1], E. Buyse[1], R. Cooreman[1], H. Tournaye[1], M. De Vos[1]

[1]UZ Brussel, Centre for Reproductive Medecine, Brussels, Belgium

Study question: In Belgium, by law, a retention period of 10-years is standard. Is this period sufficient for women to return to the clinic and use their vitrified oocytes?

Summary answer: A standard cryopreservation period of 10-years seems sufficient since half of the women returned to the fertility clinic and 96% used the vitrified oocytes.

What is known already: The main driver for elective oocyte cryopreservation is to buy more time to find a suitable partner. The question remains whether 10 years of cryopreservation is sufficient for women to accomplish their goal of finding a partner and procreate with or without using their vitrified oocytes. The return rates and the utilisation rates of the vitrified oocytes reported in the literature are low. Most women do not use their vitrified oocytes. Little is known about women's reproductive pathways after EOV and the destination of the expired surplus vitrified oocytes.

Study design, size, duration: Computerized clinical data were retrieved from a pioneer cohort of women who underwent EOV in our centre for age-related reasons more than 10 years ago (between 2009 and 2012). Hence, the legal cryopreservation period of their oocytes expired between 2019 and 2022. We documented reproductive choices for those who returned to the centre and we investigated the intended destination of the expired vitrified oocytes for those who did not return.

Participants/materials, setting, methods: Data were collected from clinical charts of women who vitrified oocytes. According to Belgian law, unused vitrified oocytes expire when reaching the age limit of 48 years for use or by reaching the standard cryopreservation period of 10 years. We evaluated whether women eventually started treatment, assessed their relational status, the utilisation rate of the vitrified oocytes and the intended destination of the vitrified oocytes as stated in their informed consents.

Main results and the role of chance: 117 women vitrified their oocytes at least 10 years ago. Women's oocyte cryopreservation period expired because they were either beyond the age limit for use (n = 82) or because the legal oocyte cryopreservation period of 10 years was reached (n = 35). Five women requested transport of their oocytes for treatment in a centre abroad.

Fifty-two out of 117 women (44.4%) returned for assisted reproduction. Eventually, 96% (50/52) of them used their vitrified oocytes for treatment and 21/50 had a child or ongoing pregnancy. Upon return to the clinic, 22 women were single and 27 had found a partner, two women returned with a co-parent and one woman had a female partner. Furthermore, 7/117 women returned to the clinic but eventually refrained from treatment.

Fifty-one women never returned to the centre. Only five women asked to prolong the cryopreservation period for medical reasons. The others not using their vitrified oocytes, did not initiate further action concerning the cryopreservation period, use or destination of their stored oocytes. Hence, the destination of the cryopreserved oocytes was according to the women's choice stated in the informed consent. The majority donated their oocytes for research (60%), others (31%) opted to destroy the oocytes after 10 years of cryopreservation.

Limitations, reasons for caution: It was not possible to map out the reproductive pathway of women who did not return to the centre and whose vitrified oocytes expired for use. Follow-up of reproductive choices and outcomes in women who did not return for treatment is required for a comprehensive appraisal of EOV.

Wider implications of the findings: The vast majority of the women who returned for treatment used their vitrified oocytes. Those not returning did not initiate further action concerning the use or destination of their vitrified oocytes. These results add to our knowledge on the utilisation rate after EOV, essential to improve counselling of future EOV-candidates.

P-589 How Does Hypothyroidism Alter Perinatal Outcomes in Patients with Polycystic Ovary Syndrome? - An Evaluation of a Population Database

A. Hochberg[1], A. Badeghiesh[2], H. Baghlaf[3], M. Dahan[4]

[1]McGill University, Department of Obstetrics and Gynecology-, Montreal, Canada
[2]University of Western Ontario, Department of Obstetrics and Gynecology, London, Canada
[3]McGill University, Department of Obstetrics and Gynecology, Montreal, Canada
[4]McGill University, Obstetrics and Gynecology, Montreal- QC, Canada

Study question: Does concomitant hypothyroidism in polycystic ovary syndrome (PCOS) patients have an additive effect on the risk for adverse pregnancy, delivery and neonatal outcomes?

Summary answer: In patients with PCOS, hypothyroidism significantly increases the risk for preeclampsia, however risks of other adverse perinatal outcomes are unaltered.

What is known already: PCOS and hypothyroidism are common endocrinopathies during reproductive age, and each has been shown to be associated with pregnancy complications. While PCOS has been associated with gestational diabetes, gestational hypertension, and preeclampsia, overt hypothyroidism has been associated with pregnancy loss, intrauterine growth restriction, preeclampsia, and preterm birth. Furthermore, PCOS and thyroid abnormalities are known to be linked, with a higher prevalence of thyroid dysfunction in pregnant PCOS patients compared to controls. However,

information on obstetric and neonatal outcomes in women with both PCOS and hypothyroidism is lacking.

Study design, size, duration: A retrospective population-based study utilizing data from the Healthcare Cost and Utilization Project—Nationwide Inpatient Sample (HCUP-NIS), was performed. A dataset of all deliveries between 2004 and 2014 inclusively, was created. This population-based cohort study included 14,882 women with an International Classification of Diseases (ICD)-9 diagnosis of PCOS in the United States. IN 2015 data was converted to ICD-10 codes which are not comparable to ICD-9 codes.

Participants/materials, setting, methods: All pregnancy admissions that resulted in delivery or maternal death were included so that patients were counted only once per pregnancy. We compared PCOS women with a concurrent diagnosis of hypothyroidism to those without. Women with hyperthyroidism were excluded. Pregnancy, delivery, and neonatal outcomes were compared between the two groups. Multivariate logistic regression analysis was used to adjust for confounding effects.

Main results and the role of chance: Overall, 14,882 women met the inclusion criteria. Amongst them, 1,882 (12.65%) had a concomitant diagnosis of hypothyroidism, and 13,000 (87.35%) did not. Women with concomitant hypothyroidism, compared to those without, were characterized by increased maternal age (25.5% $\geq$35 years vs. 18%, $p < 0.001$, respectively), and had a higher rate of multiple gestations (7.1% vs. 5.7%, $p = 0.023$). Interestingly, pregnancy, delivery, and neonatal outcomes were comparable between the groups, except for a higher rate of small-for-gestational-age (SGA) neonates in the group with hypothyroidism (4.1% vs. 3.2%, $p = 0.033$), when not accounting for confounding effects. In a multivariate logistic regression adjusting for potential confounders, hypothyroidism was no longer found to be associated with SGA (adjusted odds ratio [aOR] 1.32, 95% confidence interval [CI] 0.99-1.75, $p = 0.057$), but was found to increase the odds for preeclampsia (aOR 1.30, 95% CI 1.06-1.59, $p = 0.012$). Of note when controlling for confounding effects, all other pregnancy, delivery, and neonatal outcomes were comparable between the groups, including pregnancy-induced hypertension; eclampsia; gestational diabetes mellitus; preterm premature rupture of membranes; preterm delivery; placental abruption; cesarean delivery; hysterectomy; post-partum hemorrhage; wound complications; maternal death; blood transfusions; maternal infection; venous thromboembolism; disseminated intravascular coagulation; SGA; intrauterine fetal death; and congenital anomalies.

Limitations, reasons for caution: Due to our study's retrospective nature, some data is missing such as TSH levels, TPO antibody status, the time period in which hypothyroidism was diagnosed (pre-gestationally or during the 1st, 2nd or 3rd trimesters), and Levothyroxine treatment dose and compliance.

Wider implications of the findings: Patients with PCOS and hypothyroidism during pregnancy should be managed with consideration of instituting both preventive measures for preeclampsia development and heightened blood pressure, proteinuria, and symptom monitoring. Interestingly, hypothyroidism did little to affect the already increased rates of pregnancy complications in PCOS. This should be further studied.

P-596 Rectal progesterone administration secures high ongoing pregnancy rate in a personalized Hormone Replacement Therapy Frozen Embryo Transfer (HRT-FET) protocol - a prospective interventional study

B. Alsbjerg[1,2], M.B. Jensen[1], B.B. Povlsen[1], H.O. Elbaek[1], R. Laursen[1], A. Mikkelsen[1], M.C. Reich[1], U.S. Kesmodel[3,4], P. Humaidan[1,2]

[1]*Regional Hospital Viborg - Skive Sundhedshus, The Fertility Clinic- Skive Regional Hospital, Skive, Denmark*
[2]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*
[3]*Aalborg University Hospital, Department of Obstetrics and Gynaecology, Aalborg, Denmark*
[4]*Aalborg University- Aalborg, Department of Clinical Medicine, Aalborg, Denmark*

Study question: Can supplementation with additional rectal administration of progesterone secure high ongoing pregnancy rates (OPR) in patients with low serum progesterone (P4) at blastocyst transfer (ET)?

Summary answer: Rectally administered progesterone starting on the blastocyst transfer day secures high OPR in patients with serum P4 levels lower than 35 nmol/l (11ng/ml).

What is known already: Low serum P4 levels at peri-implantation in HRT-FET cycles impact reproductive outcomes negatively. However, studies have shown that patients with low P4 after a standard vaginal progesterone treatment can obtain live birth rates (LBR) comparable to patients with optimal P4 levels if they receive additional subcutaneous progesterone, starting close to the day of blastocyst transfer. In contrast, increasing vaginal progesterone supplementation in low serum P4 patients does not increase LBR. Another route of administration rarely used in ART is the rectal route, although progesterone is well absorbed and serum P4 levels reach a maximum level after approximately two hours.

Study design, size, duration: This prospective interventional study included a cohort of 488 patients treated with single blastocyst HRT-FET, in which a total of 374 patients had a serum P4 level $\geq$35nmol/l (11ng/ml) at ET, and 114 patients had a serum P4 level <35nmol/l (11ng/ml). The study was conducted from January 2020 to November 2022.

Participants/materials, setting, methods: Patients undergoing HRT-FET in a public Fertility Clinic. Endometrial preparation included oral oestradiol (6mg/24hours), followed by vaginal micronized progesterone, 400mg/12hours. Single blastocyst transfer and P4 measurements were performed on the 6th day of progesterone administration and patients with serum P4 <35nmol/l (11ng/ml) additional rectal administration of progesterone (400mg/12hour) was started the same day. In pregnant patients, vaginal and rectal administration continued until week 8, and oestradiol and vaginal progesterone treatment continued until week 10.

Main results and the role of chance: Among 488 HRT-FET single blastocyst transfers, the mean age of the patients at oocyte retrieval (OR) was 30.9 $\pm$4.6 years and the mean BMI at ET 25.1 $\pm$3.5 kg/m^2.

The mean serum P4 level after vaginal progesterone administration on the day of blastocyst transfer was 48.9 $\pm$21.0 nmol/l (15.4 $\pm$6.6ng/ml), and a total of 23% (114/488) of the patients had a serum P4 level lower than 35nmol/l (11ng/ml). The overall, positive hCG rate, clinical pregnancy rate, OPR week 12, and total pregnancy loss rate were 66% (320/488), 54% (265/488), 45% (221/488), and 31% (99/320), respectively. There was no significant difference in neither OPR week 12 nor total pregnancy loss rate between patients with P4 $\geq$35nmol/l (11ng/ml) and patients with P4 <35nmol/l, who received rescue in terms of rectally administered progesterone, 45% vs. 46%, $p = 0.77$ and 30% vs. 34%, $p = 0.53$, respectively.

OPR did not depend on whether patients had initially low P4 and rectal rescue or were above the P4 cut-off. Logistic regression analysis showed that only age at OR and blastocyst scoring correlated with OPR week 12, independently of other factors like BMI, and vitrification day of blastocysts (day 5 or 6).

Limitations, reasons for caution: In this study vaginal progesterone (Cyclogest®), a solid pessary with progesterone suspended in vegetable hard fat, was used vaginally as well as rectally. It is unknown whether other vaginal progesterone products could be used rectally as easily with the same rescue effect.

Wider implications of the findings: A substantial part of HRT-FET patients receiving vaginal progesterone treatment has low serum P4. Adding rectally administered progesterone in these patients increases the reproductive outcome. Importantly, rectal progesterone administration is considered convenient by the majority of patients; moreover, progesterone pessaries are easy to administer rectally and of low cost.

P-660 No association between BMI, oocyte yield and maturation following different trigger strategies: a large observational study including 5000 cycles.

V. Donno[1], S. Garcia[1], I. Rodrìguez[1], A. La Marca[2], N.P. Polyzos[1]

[1]Dexeus University Hospital- Barcelona- Spain., Dexeus Mujer- Department of Reproductive Medicine-, Barcelona, Spain
[2]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences for Mother- Child and Adult, Modena, Italy

Study question: Is patients' BMI associated with oocyte yield and maturation following different trigger strategies with r-hCG, GnRH agonist (GnRHa) or dual trigger?

Summary answer: Patients' BMI is not associated with oocyte yield and oocyte maturation following triggering with rhCG, GnRHa or dual trigger.

What is known already: Triggering final oocyte maturation is a key step of ovarian stimulation for IVF/ICSI treatment. Although hCG has traditionally been the gold standard for final oocyte maturation, GnRHa is increasingly used as optimal trigger in "freeze-all" era. Recent evidence has demonstrated excellent results with dual-trigger, a combination of hCG and GnRHa.

Despite this swift in clinical practice, early studies demonstrated that hCG plasma levels depend on hCG trigger dose and BMI. Furthermore, although dose-finding studies following for GnRHa trigger demonstrated equal efficacy of triptorelin doses ranging from 0.1-0.4mg, these studies pertained only to low BMI patients.

Study design, size, duration: This is a retrospective observational study including 5190 consecutive cycles ovarian stimulation cycles (OS) performed between January 2019 -September 2022 in a tertiary Fertility Unit within a University Affiliated Hospital. Overall 5190 ovarian stimulation cycles were analyzed: 2691 cycles triggered with subcutaneous administration of 0.2 mg of GnRHa (triptorelin), 1110 with 250 mcg of r-hCG and 1389 with a dual trigger (combination of both 0.2 mg triptorelin+ 250 mcg of r-hCG).

Participants/materials, setting, methods: Ovarian stimulation was performed with recombinant FSH or HMG at a starting dose 150-300IU depending on patients' ovarian reserve and BMI. Control of LH surge was accomplished by a flexible GnRH antagonist or PPOS protocol. The primary outcome measures were oocyte maturation rate (MII/oocytes) and FOI (oocytes/AFC); secondary outcomes were oocyte and MII yield. Multivariable regression models were performed to evaluate the interaction between BMI and type of trigger in relation to study's outcomes.

Main results and the role of chance: Overall, oocyte and MII yield was significantly different between different types of trigger mainly due the fact that GnRHa was primary used in freeze-all cases, with excellent ovarian reserve. This resulted in a higher number of oocytes (15.95 ± 8.88) and MIIs (12.31 ± 7.27) as compared with cycles triggered with in rhCG (7.83 ± 5.42 and 5.86 ± 4.22 respectively) or dual trigger (8.51 ± 5.70 and 6.44 ± 4.54 respectively) was utilized. Nonetheless, when oocyte maturation rate was comparable between trigger groups (% [95% CI]): GnRHa 77.2 [76.6; 77.8] vs rhCG 74.9 [73.3; 76] vs dual 75.6 [74.5; 76.7].

Multivariable regression analysis, adjusting for confounding factors, demonstrated that BMI was not associated with oocyte maturation rate (OR:1.00 [95% CI: 0.99;1.01]) and FOI (Beta 0.52 [95% CI: -0.49;1.54]). Similarly BMI was not associated number oocytes (Beta 0.02 [95% CI: -0.08; 0.13]) or on the number of MIIs (Beta 0.01 [95% CI: -0.08; 0.10]) retrieved. Interactions between BMI and trigger groups were considered in each model. All analyses were conducted considering patients' weight, but no association was revealed.

Limitations, reasons for caution: This is a retrospective study, and we cannot exclude the presence of residual bias despite the large series, the multiple regression models and the indexes like maturation rate and FOI we adopted to account for confounding factors.

Wider implications of the findings: Although previous small observational studies supported an association between BMI and hCG levels, our large analysis of > 5000 cycles clearly shows that the efficiency of r-hCG, triptorelin or dual trigger is not associated with the patient's BMI and weight, as no significant differences were found in maturation rate and FOI.

P-653 Natural proliferative phase frozen embryo transfers: a novel, safe and efficient transfer strategy

C. Santana[1], J.M. Mascarós Martinez[2], A.R. Neves[1], T. Semenova[1], S. G. Nunes[1], S. Reis Soares[1], S. Santos-Ribeiro[1]

[1]IVIRMA, IVI Lisboa, Lisboa, Portugal
[2]IVIRMA, IVI Foundation, Valencia, Spain

Study question: How do natural proliferative phase for frozen embryo transfers (NPP-FET) compare to traditional artificial and natural cycle FETs in terms of pregnancy and neonatal outcomes?

Summary answer: NPP-FETs were associated with similar ongoing pregnancy rates after 22 weeks, but with less miscarriage rates comparing to artificial cycles.

What is known already: The best FET protocol for endometrial preparation is still controversial. A natural cycle (NC) FET may require more visits to the clinic and provides less flexibility. Conversely, artificial cycles (AC), although being more flexible in terms of scheduling, have been previously associated with higher rates of miscarriage and maternal morbidity. Here we describe an alternative FET strategy (NPP-FET) in which, during an unmediated ovulatory cycle, progesterone is initiated as soon as the endometrium proliferation reaches 7 mm of thickness, regardless of the size of the dominant follicle and without the administration of exogenous hCG or spontaneous LH peak.

Study design, size, duration: We performed a single center retrospective cohort study of FET cycles performed between January 2020 and June 2022 (n = 2158). Only single embryo blastocyst stage transfers were included. The main outcome was ongoing pregnancy rate after 22 weeks. Secondary outcomes included the number of visits to the clinic during monitoring, serum levels of progesterone on the day of FET, livebirth (LBR) and miscarriage rates, and maternal/perinatal outcomes.

Participants/materials, setting, methods: FETs cycles were divided in three subgroups: NC, NPP and AC. For the main outcome measures, a multivariable logistic regression was performed, to adjust for potential confounding (oocyte age/source, use of PGT-A and embryo quality), followed by pairwise comparisons whenever statistically significant.

Main results and the role of chance: In total, 2158 FET cycles were analysed (1219 NC, 277 NPP and 662 AC). The mean number of visits before FET planning were 2.14, 1.83 and 1.33 for NC, NPP and AC FETs, respectively ($p < 001$ for all pairwise comparisons). Mean progesterone levels on the day of transfer were significantly higher after NPP and NC (29.4 ng/mL and 40.2ng/mL, respectively), compared to AC (12.7 ng/mL). Progesterone rescue therapy (administered whenever serum progesterone <8.8 ng/mL) was also significantly more frequently needed following AC (24,9% for AC versus 0.6% and 2.6% in NC and NPP, respectively). The ongoing pregnancy rates after 22 weeks were 57.3% for NC, 55.6% for NPP and 54.5% for AC. LBRs following NPP were comparable with NC (38.9% and 42.7%, respectively), and significantly lower with AC (36.0%) compared to NC. The miscarriage rates were significantly lower after NPP and NC-FET when compared to AC (18.4%, 24.3% and 30.7% respectively). Considering maternal outcomes, NPP and NC were associated with a significantly lower risk of first trimester bleeding compared to AC (17.5%, 13.8% and 36.7%, respectively). The rate of gestational hypertensive disorders did not vary significantly (7.5% for NPP, 9.9% for NC and 12.6% for AC).

Limitations, reasons for caution: While serum progesterone and miscarriage rates comparable to NC-FET allude to the possibility that ovulation may still occur in NPP-FETs, this study cannot establish such causality due to its retrospective design. Moreover, the study may have been underpowered to detect clinically relevant subgroup differences such as for hypertensive disorders.

Wider implications of the findings: NPP-FETs seems to be an effective and safe alternative, potentially wielding both the advantages of the natural proliferative endometrium of the NC with the ease for scheduling of ACs.

Nonetheless, further investigation is warranted attempting also to confirm whether ovulation does indeed still occur despite the progesterone administration.

[5]Uppsala University, Department of Women's and Children's Health, Uppsala, Sweden
[6]Utrecht University, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands
[7]Vrije Universiteit Amsterdam, Amsterdam Institute for Life and Environment, Amsterdam, The Netherlands
[8]University of Tartu, Department of Obstetrics and Gynaecology, Tartu, Estonia

Study question: Can higher concentrations of di-2-ethylhexyl phthalate (DEHP) in follicular fluid (FF) lead to an altered microRNA expression profile?

Summary answer: The present study indicates the upregulation of miR-203a-3p, miR-150-5p and miR-28-3p in the follicular fluid of women with higher DEHP concentrations (FDR<0.05).

What is known already: Women are exposed daily to endocrine-disrupting chemicals (EDCs) such as phthalates which can be found in hundreds of personal care products and plastic items. In studies of rodents exposed to certain phthalates, high doses have been shown to change hormone levels, disrupt folliculogenesis and cause birth defects. Recently, we reported a strong inverse association between DEHP metabolites and ovarian sensitivity index (OSI) in females undergoing ART treatment. Several mechanisms have been proposed to explain the association between DEHP and fertility in rodents, however not much is known about the mechanisms in humans.

Study design, size, duration: FF was collected from 96 women undergoing IVF treatment after controlled ovarian stimulation during ovarian puncture. 48 participants from Estonia were recruited at Nova Vita Clinic AS in Tallinn, Estonia in 2019 and 48 participants from Sweden were recruited at Carl von Linnekliniken in Uppsala, Sweden in 2016. In both cohorts, patients signed a written informed consent form. Both cohorts were matched for age, BMI, parity and the number of previous IVF treatments.

Participants/materials, setting, methods: DEHP metabolite concentrations in the FF samples were measured in our earlier study by LC-MS/MS. Cell free RNA was extracted from FF samples with Qiagen miRNeasy Micro kit, sequencing libraries were prepared with QIAseq miRNA library kit and sequenced on Illumina NextSeq 550 instrument. Differential miRNA expression analysis was performed with the DESeq2 package. Pathway enrichment analysis for differentially expressed miRNA targets was conducted with the miEAA tool integrated with WikiPathways.

Main results and the role of chance: In total, 465 miRNAs were observed at least twice in ≥ 24 samples. Differential expression analysis was conducted between DEHP-high and DEHP-low groups in combined cohorts using the cohort as a covariate. 16 miRNAs were found to be differentially expressed between DEHP groups with FDR<0.1. Three miRNAs: miR-203a-3p, miR-150-5p and miR-28-3p, were differentially expressed with FDR<0.05 and were more abundant in women with high DEHP-levels in both cohorts. Of these, miR-203a-3p was negatively correlated with OSI (Pearson R = -0.27, p = 0.0089). Six miRNAs (miR-10b-5p, miR-112-5p, miR-132-5p, miR-203-3p, miR-205-5p and miR-27-3p) were found to have predicted targets in the androgen receptor signalling pathway.

Limitations, reasons for caution: The miRNAs found in this study need to be validated in a larger set of patients as a cohort-dependent difference in the results was observed. There is a need for further functional studies to investigate miRNAs as possible mediators of the association between DEHP and ovarian sensitivity index.

Wider implications of the findings: The current study presents evidence that DEHP exposure alters the expression of FF miRNAs which are associated with androgen receptor signalling. These results provide novel evidence of the potential influence of endocrine-disrupting chemicals on female reproduction.

P-676 Bone health in Australian women with early menopause: a 23-year longitudinal analysis

A. Jones[1], P. Ebeling[2], G. Mishra[3], H. Teede[1], J. Entiocott[1], A. Vincent[1]

[1]Monash University, Monash Centre for Health Research and Implementation, Melbourne, Australia
[2]Monash University, School of Clinical Sciences, Melbourne, Australia
[3]University of Queensland, School of Public Health, Brisbane, Australia

Study question: What is the frequency of osteoporosis, fractures, and osteoporosis management in women with early menopause (menopause <45years; EM)? What factors influence osteoporosis, screening, and treatment?

Summary answer: Osteoporosis risk is 80% higher in women with early versus natural age menopause. Despite higher screening and treatment, gaps persist in managing EM bone health.

What is known already: A treatment gap in osteoporosis care exists, with low diagnosis (using dual X-ray absorptiometry, DXA), and primary or secondary fracture prevention. Women with EM have increased rates of osteoporosis. Clinical guidelines recommend screening with DXA and menopause hormone therapy (MHT) for most women with EM to reduce osteoporosis and fracture risk. However, studies suggest osteoporosis knowledge, guideline uptake and management adherence by clinicians and women is limited.

Study design, size, duration: The Australian Longitudinal Study on Women's Health is a prospective longitudinal study of Australian women. This study uses the cohort of women born between 1946 – 1951, surveyed nine times between 1996 – 2019. Data from Australian administrative health records including the Pharmaceutical Benefits Scheme (PBS) (MHT, Bone specific agents; BSA) and Medicare benefits schedule (DXA) was linked to survey data.

Participants/materials, setting, methods: Respondents with self-reported age of menopause were included. EM defined as above. T-test/chi-square used for comparisons at baseline ($p < 0.05$ indicates significance). Generalised estimating equations (GEE) for panel data explored longitudinal outcomes of osteoporosis, fractures, DXA rates, MHT use and BSA (in women with osteoporosis/fracture). Univariable regression was performed, and variables retained where $p < 0.2$, to form the multivariable model, and bootstrapping with 100 repetitions at 95% sampling of the original dataset to ensure robustness of results.

Main results and the role of chance: 8,603 women were included: 610 (7.1%) with EM. Mean (SD) baseline age was 47.6 (1.45) years in the entire cohort, and mean (SD) age of menopause was 38.2 (7.95) and 51.3 (3.04) years in women with EM and natural age menopause, respectively ($P < 0.001$). Overall, 421 (69.0%) women with EM had DXA screening, 305 (50%) had a fracture/osteoporosis, 474 ever used MHT (77.7%) and 142 (46.6%) used BSA.

Using the multivariable model, women with EM had increased risk of osteoporosis (Odds Ratio (OR) 1.80; 95%CI 1.43,2.26), fractures (OR 1.48; 1.18,1.85), MHT use (OR 6.98; 5.78,8.43) and BSA use (OR 1.69; 1.24,2.32).

In EM women, increasing age was associated with greater risk of osteoporosis / fracture (OR 1.09; 1.08,1.11), and MHT use did not significantly reduce this risk (OR 0.78; 0.55,1.11). In EM women, age (OR 1.32; 1.12,1.15), BMI (OR 0.94; 0.91,0.96), current smoking (OR 0.51; 0.35,0.74) and inner (OR 0.69; 0.52,0.91) or outer regional (OR 0.66; 0.46,0.95) residential location were associated with DXA screening. In EM women, increasing age (OR 1.15; 1.13,1.18) and lower BMI (OR 0.91; 0.86,0.95) were associated with BSA use.

Limitations, reasons for caution: Survey data were self-reported by participants, and fracture questions were not included in the 2001 survey. PBS data was only available from 2004, and hospital admissions data for all of Australia was only available from 2007.

Wider implications of the findings: Osteoporosis and fractures affect a significant number of women with EM. Focus must be made on improving screening and treatment of these women.

O-039 Fertilization: Mechanisms of pronuclear migration and genome unification

T. Cavazza[1]

[1]*University of Zurich, Department of Reproductive Endocrinology, Schlieren, Switzerland*

Most early human embryos contain aneuploid cells. Aneuploidy often arises during the early mitotic divisions of the embryo, but its origin remains elusive. Human zygotes that cluster their nucleoli at the pronuclear interface are thought to be more likely to develop into healthy euploid embryos.

I will present data showing how the parental genomes cluster with nucleoli in each pronucleus in human and bovine zygotes. Parental genome clustering is required for the reliable unification of the parental genomes after fertilization. During the migration of intact pronuclei, the parental genomes polarize toward each other in a process driven by centrosomes, dynein, microtubules, and nuclear pore complexes. The maternal and paternal chromosomes eventually cluster at the pronuclear interface, in close proximity to each other, yet separated. Parental genome clustering ensures the rapid unification of the parental genomes upon nuclear envelope breakdown. However, clustering often fails, leading to chromosome segregation errors and micronuclei that are incompatible with healthy embryonic development.

In summary, our data reveal why nucleolar clustering correlates with the formation of healthy euploid embryos. In addition, we used automated analysis of nucleolar trajectories and clustering. Our results support the use of nucleolar clustering as a parameter to identify zygotes with higher developmental potential.

Abstract citation ID: dead093.046
O-040 Clinical competence of oocytes with developmental abnormalities

S. Ziebe[1]

[1]*Copenhagen University Hospital, The Fertility Department, Copenhagen, Denmark*

For decades we have looked for marker of embryo competence. And while we have come a long way in terms of identifying markers related to embryonic competence, a lot of research is still focused on finding this simple measurable indicator predicting a positive outcome of the individual treatment. Many potential indicators have been evaluated. This includes the cumulus oocyte complex, zona pellucida, perivitelline space, polar bodies, vacuoles, refractile bodies, SER clusters, cytoplasmic granularity, and many others. For some of these there are data suggesting potential prediction of negative outcome (for review see Bartolacci et al. 2022). Embryo autonomy may result in cleavage and development despite the lack of competence to establish a pregnancy. And pregnancies may occur without the competence to go all the way to a live birth. In a study by Lundin et al. we looked into chromosomal constitution after rescuing immature (developmentally abnormal) human oocytes. And while 15% of the oocytes developed into an embryo only very few appeared chromosomally normal after cytogenetic analysis. The study concluded that the majority of hCG exposed oocytes that have not reached the MII stage at time of pick-up are defect and consequently that GV or MI oocytes should not be used in ART programs.

As reproductive specialists our main task is to assist our patients in achieving their dream of having a child. We are supposed to use all our combined expertise, knowhow, craftmanship, routine and experience to optimize the chance for the patients to have a baby.

However, in our ambition to help our patients we sometimes lose touch of the underlying biology of human reproduction. Oocytes from a stimulated ovary are not like those we buy in the supermarket of equal quality. The depressing fact is that only 5.0 % of the oocytes in a first cycle is biologically competent and in around 2/3 of all cycles, none of the oocytes have the potential to result in the birth of a child (Lemmen et al 2016). We also have very limited ability to determine competence of individual sperm cells – the strongest prognosticator being if they look and move like a "normal" sperm sample.

Are we getting a bit desperate when we start to look for normality in the abnormal as suggested in the title of this talk? Have we reached a point were patient expectations overrides our biological training and education resulting in low willingness to accept a negative outcome dictated by our biology? And is this reinforced by patient perceptions like "*we did not pay a lot of money for the oocytes not being fertilized/developed/implanted*".

Embryo competence evaluation is based on markers of what have happened rather than indicators of what will happen. At the end of the day, we as health care professionals as well as our patients needs to accept the fact that there is no such thing as "CLINICAL COMPETENCE OF OOCYTES WITH DEVELOPMENTAL ABNORMALITIES". And what will be the consequence of a marker indicating a lower implantation potential in an otherwise ok embryo? It might affect the ranking of the embryos from a particular cycle, but we would be willing transfer it anyway if needed. Embryo evaluation don't increase pregnancy chance per se. But it may decrease time to pregnancy by improved selection between the embryos available. Maybe it is time to re-focus our efforts and move from a binary normality approach identifying "developmental abnormalities" toward a more biological oriented approach mapping "developmental variation" in embryos and their impact on pregnancy potential and thus recognizing the multi-factorial nature of embryo maturation and ongoing developing competence.

[8]ESHRE Central Office, Strombeek-Bever, Belgium

Study question: Which are the trends shown in data collection XXIII of the European Society of Human Reproduction and Embryology (ESHRE) PGT Consortium compared with previous years?

Summary answer: Data collection XXIV, the year 2021, represents valuable data on PGT activity in (mainly) Europe and reports on the main trends observed, being the further expansion of blastocyst biopsy and NGS-based comprehensive testing technologies.

What is known already: The ESHRE PGT Consortium was set up in 1997 and from that time has been collecting data on PGT-M, PGT-SR and PGT-A. Since 1999, the PGT consortium has collected 105 000 embryo analyses and published 21 previous data collection sets in 17 reports. Since the year 2016 a prospective cycle-by-cycle data collection is in place.

Study design, size, duration: IVF cycle management and genetic analysis techniques are getting more complex and require more details to be reported. Therefore, ESHRE uses an online data collection system in which data are collected prospectively from oocyte retrieval to analysis, embryo transfer and pregnancy/live birth. Data are collected cycle by cycle on a voluntary basis.

Participants/materials, settings, method: For the 2021 data, individual centres (36) from 19 countries directly entered the analysis data (n = 3067) into the PGT database through software developed by ESHRE. Data were analysed at ESHRE Central Office and include all aspects of the PGT/PGT-A cycles.

Main results and the role of chance: The indications for PGT included inherited chromosomal abnormalities (n = 386 analyses), monogenic disorders (n = 1329 analyses), aneuploidy testing (n = 1147 analyses), HLA typing (alone or in combination with PGT-M (n = 4 analyses), mitochondrial disorders (5 analyses) or combinations of the above (n = 111 analyses). 85 analyses were reported without indication. In addition, 894 clinical pregnancies and 496 deliveries have been analysed in detail. The methods used for biopsy were polar body (1%), cleavage stage biopsy (16%) and blastocyst biopsy (83%), showing a continuous increase in blastocyst biopsy compared to 2020 and earlier years. The methodology used for diagnosis is what evolved most over the last years but seems to stay comparable with 2020. Data set XXIV (2021) shows around 4% of FISH, 31% of PCR and 62% of WGA. Within WGA 84% of the analyses were done using NGS, in 8% of the cases SNP arrays were used, PCR accounted for 2.5% of the analyses and in 1% array-CGH was used. In the remaining cases, combinations of the above were used. The overall clinical pregnancy rate of 29% per analysis shows an increase compared to 2020. The baby data show that it is difficult for most centres to have a detailed follow-up.

Limitations, reasons for caution: The findings apply to the 36 participating centres and may not represent worldwide trends in PGT. Data were collected prospectively, but details of the follow-up on PGT pregnancies and babies born were limited.

Wider implications of the findings: The ESHRE PGT Consortium continues its activities as an important forum for PGT practitioners to share data and exchange experiences. The information extracted from the data collection helps to monitor quality issues in PGT and survey the introduction and effectiveness of new PGT technologies and methods.

Abstract: Study question: In oocytes of advanced maternal age (AMA) women, what is the association of aneuploidy with embryo development and what are the mechanisms leading to aneuploidy?

Summary answer: We confirmed precocious separation of sister chromatids as the main cause of aneuploidy. Known chromosome segregation errors explained 90.4% of the observed abnormal chromosome copy numbers in polar bodies.

What is known already: Meiotic chromosomal aneuploidies in oocytes correlate with AMA (>35 years), and can affect over half of oocytes in this age group. This underlies the rationale for polar body (PB) biopsy as a form of early PGT-A, as performed in the 'ESHRE STudy into the Evaluation of oocyte Euploidy by Microarray analysis' (ESTEEM) randomised controlled trial (RCT). So far, chromosome analysis of oocytes and PBs has shown that precocious separation of sister chromatids (PSSC), meiosis II (MII) nondisjunction (ND) and reverse segregation (RS) are the main mechanisms leading to aneuploidy in oocytes.

Study design, size, duration: Data was sourced from the ESTEEM study, a multicentre RCT from seven European centres to assess the clinical utility of PGT-A on PBs using array comparative genomic hybridisation (aCGH) in patients of AMA (36-40 years). This included data on the chromosome complement in PB pairs, and on embryo morphology in a subset of embryos, up to day 6 post insemination (dpi), from both the intervention (PB biopsy for PGT-A) and from control (no biopsy) arms.

Participants/materials, setting, methods: ESTEEM recruited 396 AMA patients: 205 in the intervention group and 191 in the control group. Complete genetic data from 693 PB pairs were analysed. Additionally, the morphology from 1034 embryos generated from fertilized oocytes (2 pronuclei) in the PB biopsy group and 1082 in the control group were compared using age-adjusted multilevel mixed-effect ordinal logistic regression for each day of embryo scoring and summarized with adjusted odds ratios (aOR) and 95% confidence intervals (CI).

Main results and the role of chance: Overall, 461/693 PB pairs showed abnormal segregation in 1162/10810 chromosomes. The main observed abnormal segregations were compatible with PSSC in meiosis I (MI) (n = 568/1162; 48,9%), ND of chromatids in MII or RS (n = 417/1162; 35.9%) and less frequently ND in MI (n = 65/1162; 5.6%). For 112 chromosomes (112/1162; 9,6%), we observed a chromosome copy number in PB1 and PB2 that is not explained by any of the known mechanisms causing aneuploidy in oocytes.

We observed that embryos in the PGT-A arm of the RCT did not have a significantly different morphology between 2 and 6 dpi compared to the control group, indicating that polar body biopsy did not affect embryo quality.

Following age-adjusted multilevel mixed-effect ordinal logistic regression models performed for each embryo evaluation day (using the before-mentioned embryo scoring subcategories), aneuploidy was associated with a decrease in embryo quality on day 3 (aOR 0.62, 95% CI 0.43-0.90), day 4 (aOR 0.15, 95% CI 0.06-0.39) and day 5 (aOR 0.28, 95% CI 0.14-0.58).

Limitations, reason for caution: RS cannot be distinguished from normal segregation or MII ND using aCGH. The observed segregations were based on the detected copy number of PB1 and PB2 only and were not confirmed by the analysis of embryos. The embryo morphology assessment was static and single observer.

Wider implications of the findings: Our finding of frequent unexplained chromosome copy numbers in polar bodies indicates that our knowledge of the mechanisms causing aneuploidy in oocytes is incomplete. It challenges the

dogma that aneuploidy in oocytes is exclusively caused by missegregation of chromosomes during meiosis I and II.

Study funding/competing interest(s): Data was mined from a study funded by ESHRE. Illumina provided microarrays and other consumables necessary for aCGH testing of polar bodies. None of the authors have competing interests.

This work is dedicated to the memory of Professor Joep Geraedts.

In 1960, the first hormonal contraceptive agent, Enovid approved by the Food and Drug Administration in the United States. The pill contained mestranol 150 mcg and norethynodrel 10 mg. High dose pills containing >50 mcg of estrogen were discontinued in 1988 due to a higher risk of myocardial infraction and stroke secondary to thrombosis. Until recently, the only estrogens used in combination OCPs were mestranol and ethinyl estradiol (EE). Estetrol (E4) and 17-beta estradiol have been added to newer pill and intravaginal ring (IVR) formulations in order to reduce the risk of thrombosis. Progestins confer the primary contraceptive effect in combination agents and can be used without estrogens. First generation progestins include norethynodrel, ethynodiol diacetate, norethindrone and norethindrone acetate (estranes). Second generation progestins include norgestrel and levonorgestrel (gonanes). Third generation include gestoden, desogrestrel and norgestimate, which are less androgen versions of the second generation progestins. Fourth generation progestins have no androgenicity include drospirenone. The fourth generation progestin is a 17 carbon compound which separates it from the other progestins that are primarily 19 carbon derivatives of androgens. Segesterone acetate (SA) is a newer progestin that is less potent and has no androgenic properties. SA, combined with EE, is currently being used in an IVR. However, clinical trials are ongoing using SA with 17-beta estradiol in an IVR and another with EE as a contraceptive gel. Other new methods of hormonal contraception include progestins in a biodegradable implant, longer acting injectables that can last 6-12 months, transdermal patches that are imbedded with an array of microneedles where either the contraceptive agent is in a reservoir or in the needles themselves. Microchip technology is being developed by the Gates Foundation that would allow levonorgestrel to be released systemically at will over a 16-year period using a remote device. Multipurpose technologies are being developed utilizing contraceptive pills, injectables and IVRs containing hormonal agents as well as medications to prevent STI/HIV acquisition.

Many lifestyle factors have been identified as risk factors for male infertility. For example, an unbalanced diet leading to overweight, obesity, metabolic disorders, and micronutrient deficiencies can have consequences for male reproductive functions. Obese men present more often altered semen parameters and a reduced chance of pregnancy naturally or after medically assisted procreation. In some cases, weight loss can reverse the adverse effects of obesity. However, few interventional studies have demonstrated the effectiveness of a preconceptional intervention in men.

In contrast, more and more studies are highlighting the importance of a balanced diet and physical activity to improve fertility. A qualitatively adequate and balanced diet and appropriate daily intake of micronutrients are fundamental for male reproductive functions. Some teams have highlighted the benefits of the Mediterranean diet on sperm production, whereas the Western diet, including reconstituted meats, fried foods, and sweet foods and drinks, was associated with altered semen parameters. However, few interventional studies have confirmed the impact of men's diets on the chances of natural or medically assisted pregnancy and live birth, and their results are controversial.

Therefore, robust randomised controlled studies are needed. Practical advice and education can be recommended to men who wish to conceive to help them maintain or achieve the public health recommendations that encourage a balanced diet, such as the Mediterranean diet.

[5]University of Aberdeen, Aberdeen Centre for Women's Health Research, Aberdeen, United Kingdom
[6]Amsterdam Reproduction and Development Research institute- Amsterdam University Medical Centre- location AMC and VUmc, Department of Obstetrics and Gynecology, Amsterdam, The Netherlands

Study question: To compare the effectiveness of levonorgestrel-releasing intrauterine system (LNG-IUS 52mg) with hysteroscopic niche resection in the reduction of niche-related postmenstrual spotting.

Summary answer: In women with niche-related postmenstrual spotting, LNG-IUS did not more often reduce spotting days with 50% at 6th month than hysteroscopic niche resection.

What is known already: Both Levonorgestrel intrauterine system (LNG-IUS) and hysteroscopic niche resection are widely implemented to reduce niche-related postmenstrual spotting. The study aimed to compare the effectiveness of LNG-IUS 52mg with hysteroscopic niche resection in the reduction of niche-related postmenstrual spotting.

Study design, size, duration: A randomised, open-label, controlled trial conducted at one medical center in Shanghai, China. From September 2019 to January 2022, we randomised 208 women to LNG-IUS (N = 104) or hysteroscopic niche resection (N = 104).The primary outcome was reduction of postmenstrual spotting at 6th month after randomisation, defined as percentage of women with a reduction of at least 50% in spotting days from baseline. Efficacy and safety were assessed by an intention-to-treat analyses.

Participants/materials, setting, methods: Women with symptoms of postmenstrual spotting after CS, with a niche depth of at least 2 mm and residual myometrium of at least 2.2mm on Magnetic Resonance Imaging (MRI), and no intention to conceive within the next year were randomly assigned to treatment with LNG-IUS 52mg or a hysteroscopic niche resection.

Main results and the role of chance: At 6th month follow-up, a 50% reduction of spotting had occurred in 78.4% (80/102) women in the LNG-IUS group and 73.1% (76/104) women in the hysteroscopic niche resection group (RR = 1.07, [95%CI 0.92-1.25]; P = 0.370). Spotting reduced over time (P_{trend}=0.001), with a stronger reduction in the LNG-IUS group (P = 0.001), while there was also a significant interaction between time and treatment (P = 0.007). From nine months onwards, reduction of spotting occurred significantly more after LNG-IUS than hysteroscopic niche resection (9th month 89.2% vs. 72.1%, RR = 1.24, [95% CI 1.08-1.42]; 12th month 90.2% vs. 70.2%, RR = 1.29, [95% CI 1.12-1.48]).

Moreover, compared with the hysteroscopic niche resection group, the LNG-IUS group had significantly fewer postmenstrual spotting days and total bleeding days from six months onwards (all P < 0.001), and less pelvic pain from three months onwards (all P < 0.010).

Intervention-related complications were not reported in any of the groups. During follow-up, eleven (10.8%) women reported hormonal related side-effects and two (2.0%) women had spontaneous partial expulsion in the LNG-IUS group, while in the hysteroscopic niche resection group three unintended pregnancies were reported.

Limitations, reasons for caution: Due to the nature of the intervention, it was not possible to blind participants and gynaecologists for treatment allocation.The cut-off value chosen for our primary outcome and the moment of assessment for our primary endpoint can both be debated.

Wider implications of the findings: LNG-IUS provides an alternative treatment for women with niche-related gynaecological symptoms and no active desire to become pregnant.

P-757 The classification and management of adnexal masses identified during pregnancy

J. Barcroft[1], M. Pandrich[2], C. Landolfo[1], S. Del Forno[3], N. Parker[1], N. Cooper[1], M. Pikovsky[1], S. Murugesu[1], A. Novak[1], C. Kyriacou[1], M. Al Memar[1], J. Yazbek[2], D. Timmerman[4], S. Saso[1], T. Bourne[1]

[1]Imperial College London, Department of Metabolism- Digestion and Endocrinology, London, United Kingdom
[2]Imperial College Healthcare NHS Trust, Department of Obstetrics and Gynaecology, London, United Kingdom
[3]University of Bologna, Gynaecology and Human Reproduction Physiopathology, Bologna, Italy
[4]KU Leuven, Department of Development and Regeneration, Leuven, Belgium

Study question: How do we classify adnexal masses (ovarian cysts) identified during pregnancy and how should we manage them?

Summary answer: Adnexal masses (ovarian cysts) should be managed expectantly in pregnancy, given the low rate of complications and low prevalence of malignancy.

What is known already: Conservative management of adnexal masses (ovarian cysts) is preferable during pregnancy, due to the maternal and fetal risks associated with surgery. Accurate diagnosis is key to safe expectant management. Various ultrasound-based models exist to classify adnexal masses; however, none have been validated for use in pregnancy. Adnexal mass morphology can change during pregnancy due to decidualisation, which is often difficult to distinguish from underlying neoplastic processes. We aim to evaluate:(1) the performance of current methods of adnexal mass classification in pregnancy, (2) understand the natural course of adnexal masses in pregnancy, particularly the presence of decidualisation and incidence of complications.

Study design, size, duration: Retrospective analysis of prospectively collected data between January 2017- November 2022. To classify adnexal masses (ovarian cysts), we evaluated: Expert subjective assessment (SA), IOTA Simple Rules (SR) and the IOTA Assessment of Different Neoplasias of the Adnexa (ADNEX) model. The end point was either the histological examination of tissue removed at surgery or the subjective classification of adnexal masses at the postnatal scan in women managed conservatively.

Participants/materials, setting, methods: Women with an adnexal mass identified on gynaecological ultrasound in pregnancy at a tertiary London University Hospital were included. Relevant clinical data was extracted, including age, gestation and cyst-related complications. Adnexal masses were classified at the first antenatal and postnatal ultrasound examination according to SA, SR and the ADNEX model (10% risk of malignancy cut off) and correlated to histology for adnexal masses managed surgically. IOTA simple descriptors were used to classify benign adnexal masses.

Main results and the role of chance: 254 women (median age 33-years old, range:18-49) with an adnexal mass/cyst were included at a median gestation of 12 weeks, (range:4-36). 13 (5.1%) conceived through assisted reproductive techniques. Spontaneous resolution occurred in 24.5% of cases, and 21 were lost to follow up (8.3%). According to Simple Descriptors,

38.6% were simple, 22.0% were endometriomas and 19.7% were dermoid cysts.

Antenatally, SA outperformed ADNEX, based on specificity (94.6 vs.92.2%) and sensitivity (60 vs.55.6%) respectively. SA and ADNEX had a negative predictive value(NPV) of 96.1% and 98.3% respectively. Postnatally, SA had a higher sensitivity than ADNEX (75 vs.50%), but a lower specificity (94.1 vs.96.9%). SA and ADNEX had a NPV of 94.1% and 97.5% respectively.

Three (1.3%) underwent acute surgery during pregnancy: one ovarian torsion (9/40), and two cyst ruptures (11/40, 30/40). Presumed decidualisation occurred in 29.5% of endometriomas. Three (1.3%) underwent cyst removal during caesarean section, two for suspicion of BOTs (one had suspected decidualisation) and one for patient preference. On histology, the suspected decidualised mass was a serous BOT, and the suspected BOT was a struma ovarii.

In the postnatal period (12 weeks), four underwent surgery for suspicion of BOTs, two were confirmed BOTs and two were benign cystadenomas on histology.

Limitations, reasons for caution: The dataset as expected contains a relatively small number of malignancies (prevalence 3.9%) and so any analysis of test performance to discriminate between benign and malignant disease must be interpreted with caution. A larger prospective multicentre study is needed to do this.

Wider implications of the findings: Our data suggest that a number of cysts in pregnancy will resolve, a few will be associated with acute complications and the risk of malignancy is very low. Accordingly, the study supports an expectant management approach for adnexal masses (ovarian cysts) detected in pregnancy.

Trial registration number: Not applicable

P-755 Timeless importance of the embryo transfer technique: a real-life retrospective study comparing direct versus afterload catheters

F. Cirillo[1], V. Immediata[1], T. Carletti[1], C. Ronchetti[1], E. Morenghi[2], E. Albani[1], A. Baggiani[1], P.E. Levi-Setti[1]

[1]Humanitas Research Hospital- IRCCS, Department of Gynaecology- Division of Gynaecology and Reproductive Medicine- Fertility Center, Rozzano Milan, Italy
[2]Humanitas Research Hospital- IRCCS, Department of Biomedical Sciences-Humanitas University, Rozzano Milan, Italy

Study question: Can the embryo transfer (ET) technique influence clinical pregnancy rate (CPR)?

Summary answer: Our study demonstrated that CPR is significantly affected by the ET technique. In particular, with the afterload technique both CPR and easy transfer rates increased.

What is known already: Despite it having widely demonstrated that the occurrence of difficult ETs reduces the success of assisted reproductive technology (ART) cycles and that afterload technique has showed a decrease in the number of difficult transfers compared to the direct one, few data are available assessing pregnancy outcomes in the two different techniques. The present study represents the progression of a published prospective randomized controlled trial (RCT) performed in the same setting on a smaller population comparing direct and afterload techniques on the difficult transfer rate, but not designed to demonstrate differences in terms of CPR.

Study design, size, duration: Single center retrospective cohort analysis of 8,189 fresh and frozen single blastocyst transfers performed between January 2016 and December 2021 in a tertiary University affiliated fertility center. Of the total, 2,000 ETs were performed with the direct technique and 6,189 with the afterload one. All fresh single day-5 and single day-5 and day-6 frozen blastocyst transfers performed during the study timeframe were included.

Participants/materials, setting, methods: Direct technique was the only one used from January 2016 to September 2017. In the clinical trial recruitment period, the choice was given by randomization. From April 2019, only the afterload technique was used: the operator never had chance to choose the technique. Preimplantation genetic testing cycles, gamete donation and day-7 blastocyst transfers were excluded. CPR was the primary outcome, while difficult transfer rate the secondary one. Univariate and multivariate logistic regression have been performed.

Main results and the role of chance: During the period, 8,189 single blastocyst transfers were performed. Afterload ET showed a percentage of difficult transfers which was almost one third compared to that of the direct ET, being respectively 9.06% and 26.85% (OR 0.27, 95% CI 0.24-0.31p <0.001). Overall, the CPR between the two groups was significantly different: 44.69% in afterload ET and 41.65% in direct ET (OR 1.13, 95% CI 1.02-1.25, $p = 0.017$). As for the interaction between the two techniques and difficult transfer on CPR, only the direct difficult ET resulted in a significantly lower CPR with an OR of 0.62 (95%CI 0.49-0.77, $p < 0.001$). Lastly, among the 15 operators that performed the ETs, a range of difficult transfers from 3.8% to 45.4 % in the direct group and 0.8% to 20.5% in the afterload group was found ($p < 0.001$).

Limitations, reasons for caution: The main limitations of the study are the difference in sample sizes between the two groups, the wide range of time considered, and the 15 operators included. A further possible reason is the high prevalence of difficult transfer, probably due to the broad definition we used.

Wider implications of the findings: The study points out how in embryo transfers the use of the afterload technique instead of the direct one significantly improves clinical pregnancy rate and easy transfer rate. Since there is a limited knowledge on the embryo transfer technique impact, our findings aim to increase the effectiveness of embryo transfers.

Trial registration number: NCT05364528.

P-748 Fertility and anatomical outcome following hysteroscopic adhesiolysis of intrauterine adhesions classified according to symptoms, imaging findings and hysteroscopic appearance of the uterine cavity

B. Urman[1], K. Yakin[1], S. Ertas[2], E. Alper[2], E. Aksakal[3], S.G. Vitale[4]

[1]Koc University School of Medicine, Obstetrics and Gynaecology Department, Istanbul, Turkey
[2]American Hospital, Women's Health Center, Istanbul, Turkey
[3]American Hospital, Obstetrics and Gynecology Department, Bodrum, Turkey
[4]Universita degli studi di Cagliari, Obstetrics and Gynecology Department, Cagliari, Italy

Study question: To classify patients with dense intrauterine adhesions based on clinical characteristics as well as, ultrasound, hysterosalpingography (HSG) and hysteroscopy findings into different prognostic groups.

Summary answer: We have defined a prognostic model to classify patients with dense intrauterine adhesions which could easily be implemented in patient counseling and management.

What is known already: Intrauterine adhesions are a major cause of hypoamenorrhea and failure to conceive. A universally agreed classification to categorize intrauterine adhesions is paramount to provide individualized counseling and care. Previous efforts for categorization suffer from limitations such as variable assessment of anatomical outcomes, application of different techniques, pooling of results of different operators and lack of long-term follow-up. Many experts have voiced a call for a prognosis-oriented classification system. An ideal classification model should consider clinical characteristics, findings from imaging techniques (including ultrasound and HSG) together with hysteroscopic appearance of the uterine cavity and demonstrate a high predictive value.

Study design, size, duration: This is a retrospective analysis of 281 patients treated for intrauterine adhesions by a single operator (B.U.) between 2010 and 2021. Lysis of adhesions was affected in 479 office hysteroscopy procedures using the Versapoint bipolar cutting electrode under transabdominal ultrasound guidance. 227 patients were followed for at least 15 months after the last surgical procedure. Patients were classified into five

categories (Class I to V) according to their symptoms, ultrasound, HSG and hysteroscopy findings.

Participants/materials, setting, methods: Clinical data and operative findings were reviewed from patient files and video recordings. The number of hysteroscopic interventions needed to restore the cavity and the reproductive outcome in women who were desirous for pregnancy were recorded. Predictive power of the model was assessed using the live birth rate as the primary and rate of cavity restoration and number of interventions as the second outcome parameters. Groups were compared using ANOVA, ROC and regression analyses.

Main results and the role of chance: Adhesions were classified as class I in 43 (15.3%), class II in 72 (25.6%), class III in 57 (20.3%), class IV in 82 (29.2%) and class V in 27 (9.6%) patients. They were due to previous curettages of pregnancies (79,7%) or retained products of gestation (3.9%), prior uterine surgery (6.8%), prior hysteroscopy of inappropriate technique (6.8%) and tuberculosis (2.8%). The cavity was septate in 12 and unicornuate in 2 patients.

The mean age of the study group was 29.8 ± 3.7 (20-40). Age was not related with the severity of adhesions ($p = 0.335$). While the majority of patients with curettage-related adhesions were classified as Class II, uterine surgery, iatrogenic and tuberculosis related adhesions were higher in severity. The number of hysteroscopic adhesiolysis procedures (from 1.0 ± 02. to 2.3 ± 0.5) needed for optimal restoration of the cavity was directly related and the rate of full restoration (from 100% - 18.5%) was indirectly related with the severity of adhesions according to the proposed classification ($p = 0.0001$ for both). The live birth rates were 54.3%, 45%, 31.7%, 21% and 12.5% for patients in Class I to V, respectively ($p = 0.0001$). The proposed classification was fairly predictive (AUC: 0.654, 95%CI: 0.582-0.727) for live birth.

Limitations, reasons for caution: This is a retrospective analysis of consecutive patients with intrauterine adhesions in routine practice. The follow-up for reproductive outcome is limited. The study is hospital-based and single-center. Thus, the predictive value of the proposed classification needs to be validated in an external data set preferably in a prospective series.

Wider implications of the findings: In patients with intrauterine adhesions, a classification system based on patient symptoms, imaging findings and hysteroscopic appearance of the uterine cavity reliably predicts the postoperative outcome in terms of the extent of anatomical restoration of the uterine cavity and pregnancy and live birth rates.

O-050 The impact of embryo biopsy on obstetric and neonatal outcomes

S. Sites[1]

[1]*University of Massachusetts-Chan School of Medicine- Baystate, Obstetrics and Gynecology, East Longmeadow, U.S.A.*

Background: Preimplantation genetic testing of embryos (PGT) was performed first in 1990 to prevent the transmission of X-linked disease. Since then, the technique has improved to include couples who are both carriers of the same autosomal recessive disorder, to those with balanced translocations having recurrent pregnancy loss, and to women with advanced maternal age who are at higher risk for having aneuploid embryos. Originally, PGT involved biopsy of the polar body or of one blastomere of a cleavage stage embryo for diagnosis. The contemporary practice of PGT involves the culture of embryos to the blastocyst stage (5-7 days after fertilization), with biopsy of several trophectoderm cells that would become the placenta, transport of biopsy tissue off-site for genetic analysis, and cryopreservation of blastocysts until biopsy results are available. A single euploid embryo is then transferred into the uterus as a frozen embryo transfer.

Objective: We sought to determine if removal of these cells for preimplantation genetic testing was associated with adverse obstetrical or neonatal outcomes after frozen-thawed single embryo transfer compared to frozen-thawed single embryo transfer without biopsy. Further, we review other studies of contemporary practice of PGT to draw conclusions about the safety of the practice.

Study design: We linked assisted reproductive technology surveillance data from the Society for Assisted Reproductive Technology Clinic Outcome Reporting System to birth certificates and maternal and neonatal hospitalization discharge diagnoses in Massachusetts, USA, from 2014-2017, considering singleton births after frozen-thawed single embryo transfer. We compared outcomes of cycles having embryo biopsy ($n = 585$) to those having no biopsy ($n = 2,191$), adjusting for mother's age, race, education, parity, body mass index, birth year, insurance, and all infertility diagnoses (Sites CK et al, Am J Obstet Gynecol 2021;225:285.e1-7).

Results: With no biopsy used as the reference, we found no differences between no biopsy and biopsy groups with respect to preeclampsia, pregnancy-induced hypertension, placental disorders (placental abruption, placenta previa, placenta accreta, placenta increta, and placenta percreta), preterm birth, low birthweight, cesarean delivery, gestational diabetes mellitus, or maternal or infant length of stay after delivery. Comparing our outcomes to 4 other studies of contemporary PGT practice of frozen-thawed embryo transfers (Zhang WY Fertil Steril 2019, Li M Am J Obstet Gynecol 2020, Makhijani R Hum Reprod 2021, He H Fertil Steril 2019), our data are consistent with no effect of biopsy on low birth weight, pregnancy-induced hypertension, gestational diabetes, placenta previa, and placenta accreta. A slight decrease in preterm delivery (RR 1.10, CI 1.02-1.18), slight reduction in cesarean section (RR 0.90, CI 0.82-0.99), and increase in intrauterine growth restriction (RR 1.21, CI 1.06-1.38) are reported with biopsy in a systematic review (Hou W, Fertil Steril 2021). The increase in risk for intrauterine growth restriction with biopsy was influenced by one study (Li M Am J Obstet Gynecol 2020).

Conclusion: Embryo biopsy of trophectoderm cells for PGT in contemporary practice appears to be safe generally with respect to maternal and neonatal outcomes. There is no clear increase in diagnoses related to placentation (preeclampsia, pregnancy-induced hypertension, placental disorders, preterm birth, low birthweight), cesarean delivery, gestational diabetes

mellitus, or maternal or infant length of stay after delivery. Further study of a possible increase in intrauterine growth restriction with biopsy is indicated.

O-051 Refreezing and rebiopsy – are these worth it?

W. Verpoest[1]

[1]*UZ Brussel, Brussels IVF Fertility Centre, Jette- Brussels, Belgium*

Preimplantation genetic testing of embryos offers the opportunity to avoid the transmission of hereditary disorders to the offspring by selecting out embryos affected by a single gene mutation or mutations (PGT-M), structural rearrangements of chromosomes (PGT-SR), aneuploidy (PGT-A) as well as polygenic risk (PGT-P). Over the last two decades, laboratory techniques have seen tremendous developments including extended embryo culture to blastocyst stage, trophectoderm biopsy and vitrification. The latter technique is highly efficient and allows multiple freezing and warming cycles when performed in proficient laboratories. At the same time whole genome analysis techniques provide the opportunity to analyse embryonic DNA in great detail for multiple indications simultaneously.

The PGT process is sensitive to both biological and technical issues which sometimes lead to a failed PGT result. Failure of PGT diagnosis is reported to occur in between 2-12% of PGT cycles depending on the methodology used. The main causes of inconclusive diagnosis are DNA amplification failure and non-concurrent results. Independent variables that influence inconclusive results are day of embryo biopsy, number of cells taken at biopsy and the quality of the IVF laboratory. In order to seize every opportunity in reaching a diagnosis and optimize reproductive outcome for the patient, rebiopsy and retesting (double biopsy and double cryopreservation) can be performed. In situations where embryos need to be biopsied for PGT for reasons of newly found genetic indications or the clinical need for PGT-A, and after an initial cryopreservation, single biopsy and double cryopreservation may be performed with potential effect on subsequent reproductive outcome.

A limited number of studies have addressed both the feasibility as well as the success rate of rebiopsy and refreezing. Most studies conclude that the technique is efficient in terms of diagnostic efficiency and reproductive outcome, when performed in expert laboratories. A few studies have addressed the health of the children after multiple biopsy and multiple freezing and have not shown increased risks. Larger studies are needed to establish the true clinical and health-economic value of rebiopsy and refreezing. The speaker will give an overview of existing evidence in literature and assess whether it is safe and worthwile to go the extra mile and consider refreezing and rebiopsy for PGT.

O-052 Morphometric and morphokinetic differences in the sperm- and oocyte- originated pronuclei of male and female human zygotes: a time-lapse study

L.S. Orevich[1], **Y. Liu**[1], **K. Watson**[1], **K. Ong**[2], **I. Korman**[2], **R. Turner**[3], **D. Shaker**[4]

[1]*Monash IVF Gold Coast, Embryology, Southport, Australia*
[2]*Monash IVF Gold Coast, Clinical, Southport, Australia*
[3]*Monash IVF Auchenflower, Clinical, Auchenflower, Australia*
[4]*Monash IVF Rockhampton, Clinical, Rockhampton, Australia*

Study question: Do morphometric and morphokinetic profiles of pronuclei (PN) following intracytoplasmic sperm injection (ICSI) vary between male and female human zygotes?

Summary answer: Male and female zygotes displayed different PN morphometrics and morphokinetics. Additionally, variations were identified between sperm-originated (SPN) and oocyte-originated (OPN) pronuclei.

What is known already: Previous studies have investigated the use of PN-associated parameters via static observations as indicators of zygote viability, including size equality or juxtaposition. However, recent clinical application of time-lapse videography (TLV) provides a novel opportunity to assess these pronuclear events with greater accuracy and precision of morphometric and morphokinetic measurement. A number of recent TLV studies have also investigated potential live birth prediction by such PN associated measures, however whether or not there are sex associated differences in such measures which could in turn confound live birth prediction is unknown.

Study design, size, duration: This retrospective cohort study included 94 consecutive autologous single day 5 transfer cycles (either fresh or frozen) performed between January 2019 and March 2020. Only ICSI cycles (maternal age <40 years) leading to a singleton live birth (43 males and 51 females) were included for analysis. All oocytes were placed in the EmbryoScope incubator for culture immediately post sperm injection with all annotation performed retrospectively by one embryologist (L-SO).

Participants/materials, setting, methods: Timings included 2nd polar body extrusion (tPb2), SPN(tSPNa)/OPN(tOPNa) appearance (differentiated by proximity to Pb2) and PN fading (tPNF). Morphometrics were evaluated at 8 (stage 1), 4 (stage 2) and 0 hour before PNF (stage 3), measuring PN area (um^2), PN juxtaposition, and nucleolus precursor body (NPB) arrangement. Means ± standard deviation were compared using student t test or logistic regression as odds ratio (OR) and 95% confidence interval (CI), and proportional data by chi-squared analysis.

Main results and the role of chance: Logistic regression indicated that male zygotes had longer time intervals of tPb2_tSPNa than female zygotes (4.8 ± 1.5 vs 4.2 ± 1.0 h, OR = 1.442, 95% CI 1.009-2.061, p = 0.044), but not tPb2_tOPNa (4.7 ± 1.8 vs 4.5 ± 1.3 h, OR = 1.224, 95% CI 0.868-1.728, p = 0.250) and tPb2_tPNF (19.9 ± 2.8 vs 19.1 ± 2.3 h, OR = 1.136, 95% CI 0.957-1.347, p = 0.144). SPN increased in size from stage 1 through 2 to 3 (435.3 ± 70.2, 506.7 ± 77.3, and 556.3 ± 86.4 um^2, p = 0.000) and OPN did similarly (399.0 ± 59.4, 464.3 ± 65.2, and 513.8 ± 63.5 um^2, p = 0.000), with SPN being significantly larger than OPN at each stage (p < 0.05 respectively). However, relative size difference between SPN and OPN was similar between male and female zygotes at 3 stages (33.6 ± 61.7 vs 38.6 ± 50.8 um^2, p = 0.664; 38.5 ± 53.1 vs 45.7 ± 71.9 um^2, p = 0.585; 38.4 ± 77.4 vs 45.8 ± 63.9 um^2, p = 0.615; respectively). More male than female zygotes reached central PN juxtaposition at stage 1 (77% vs 51%, p = 0.010), stage 2 (98% vs 86%, p = 0.048) and stage 3 (98% vs 86%, p = 0.048). Furthermore, more OPN showed aligned NPBs than in SPN at stage 1 (45% vs 29%, p = 0.023), but similar proportions at stage 2 (64% vs 50%, p = 0.056) and stage 3 (76% vs 72%, p = 0.618). There were no sex associated differences detected in NPB alignment in either SPN or OPN (p > 0.05 respectively).

Limitations, reasons for caution: The retrospective design does not allow for control of unknown confounders. Sample size is considered relatively small. PN area measurement may not truly represent volume as PN may not be perfectly spherical. Findings were based on women <40 years old so may not apply to older population.

Wider implications of the finding: These findings augment and extend previous studies investigating PN parameters via static observations. The reported variations between male and female embryos may confound live birth prediction when using pronuclei morphometrics and morphokinetics. Larger scaled studies are warranted to verify these findings.

O-053 Link between cannabis use and fertility: effects on gamete competence and early embryonic development

L. Favetta[1]

[1]*University of Guelph, Reproductive Health and Biotechnologies Lab- Department of Biomedical Sciences, Guelph, Canada*

Worldwide human fertility has been facing a significant decline over recent years. Therefore, attention has been focused on identifying environmental and lifestyle risk factors that may be contributing to impact human reproductive function. The use of alcohol, tobacco and certain medications have undergone substantial assessment into their effects on fertility. As physicians aim to offer the most appropriate recommendations to their patients, it is of utmost importance to understand the side effects of readily available substances and their mechanisms of action. Cannabis falls into this group of substances used regularly by women and men of reproductive age, with its consumption steadily rising with the onset of legalization in Canada in 2018 also amongst pregnant women. At present, the Society of Obstetricians and Gynecologists of Canada recommends that women of reproductive age, especially if considering pregnancy, discontinue cannabis use. There is, however, inconclusive evidence that links cannabis and fertility.

This presentation will outline the most recent data from our laboratory on the effects of Delta-9 tetrahydrocannabinol (THC), the main psychoactive component of cannabis, on oocytes competency and sperm fertilization capability. In fact chronic exposure to cannabis also adversely affects the male reproductive system, inducing oligospermia, morphologically abnormal sperm, and impaired sperm motility in rodents. Using a bovine model as translational model for humans, we identified effects of THC on oocyte developmental parameters, gene expression as well on sperm parameters, such as motility, morphology, capacitation and mitochondrial potential. The general hypothesis at the basis of this research program aims to elucidate **the effects of THC at clinically relevant doses on gene and epigenetic modifications in sperm, oocytes and embryos, ultimately affecting fertility and pregnancy outcome.** We showed a significantly reduced ability of THC-treated oocytes to undergo nuclear maturation, ultimately leading to decreased oocyte fertilization capability and poor embryonic development. We showed that THC acts as a partial agonist at the Cannabinoid receptors 1 and 2 (CB1 and CB2), as THC effects were reverted by the addition of antagonists. The significant decrease in maturation and cleavage rate of oocytes exposed to the higher doses of THC, representative of high recreational use of Cannabis, allows us to speculate that THC might act as a selection factor for only the highest quality oocytes, that overcome the THC effects. The more immature oocytes may be negatively affected by THC by being pushed towards meiotic resumption, leading to early maturation, prior to gaining developmental competence. Levels of connexin gap-junction proteins were used as indicator of oocyte competency, as they highly correlate to oocyte fertilization potential and embryo quality. Our results demonstrated a significant decrease in *connexin 37* (CX37) and *connexin 43* (CX43) mRNA levels measured by digital droplet PCR (ddPCR), in oocytes only in the low dose THC group, representative of the therapeutic use of Cannabis. More recently we have also shown how THC affects methylation in granulosa cells, via disrupting methylation and de-methylation enzymes, ultimately determining oocyte competency and, therefore, fertility. THC exerts parallel effects on the male gametes as well, increasing capacitation of *in vitro* treated sperm, affecting their mitochondrial potential and disrupting the expression of key microRNAs in sperm that are linked to early embryonic development, therefore affecting pre-implantation development and, ultimately, pregnancy outcome.

Our results suggest an overall detrimental effect of THC on the competency and fertilization potential of both female and male gametes, negatively influencing fertility and the likelihood of a viable pregnancy, especially of importance when undergoing artificial reproductive technologies procedures.

O-054 Live Births following Laparoscopic Caesarean Scar Niche Repair in patients with Secondary Infertility: A Self-Controlled Case Series and Literature Review.

M. Deivanayagam[1], **O. Tsonis**[1], **K. Kunde**[2], **Y. Kopeika**[1]

[1]*Guys' & St Thomas' Hospital, Assisted Conception Unit, London, United Kingdom*
[2]*Guys' & St Thomas' Hospital, Gynaecology, London, United Kingdom*

Study question: Does laparoscopic repair of caesarean scar niches as a treatment for secondary infertility improve live birth rates?

Summary answer: In our self-controlled case series, the laparoscopic repair of caesarean section niches in patients with secondary infertility has improved pregnancy and live birth rates.

What is known already: A niche is an iatrogenic myometrial defect due to abnormal tissue healing at a previous caesarean section scar site. Patients with a niche present with symptoms of vaginal discharge, abnormal uterine bleeding, chronic pelvic pain, dyspareunia and secondary infertility. As a niche is secondary to caesarean sections, rising caesarean section rates will lead to an increase in the rate of niche presentation and diagnosis.

Study design, size, duration: A retrospective review was performed of all women undergoing a hysteroscopy assisted laparoscopic niche repair between 2016 and 2023 at Guy's and St Thomas' Hospital in London. The primary outcome measure was live births. A literature review was performed to interrogate the currently available evidence on live birth rate following niche repair.

Ultrasound images of the niche prior to and post repair, as well as intraoperative laparoscopic and hysteroscopic images and videos, are also presented.

Participants/materials, setting, methods: The cases were identified from the Assisted Conception Unit database. Only women who presented with secondary infertility with a diagnosis and repair of a niche were reported.

Niche diagnosis was made in patients presenting with abnormal discharge, bleeding and fluid in the uterine cavity. Any incidental myometrial defect found on transvaginal ultrasound was also a diagnostic characteristic.

Main results and the role of chance: There are some reports in the literature on pregnancy outcome following niche repair. A scarcity of studies reporting specifically on live birth rates following repair, suggests this case series as unique.

Eleven patients underwent caesarean section niche repair by two surgeons at our unit. The mean age at repair of the patients was 36. All patients had two or more years of subfertility on presentation, with a proportion having several failed in-vitro fertilisation (IVF) cycles prior to repair.

The pregnancy rate, clinical pregnancy rate and live birth rate were 73% (8/11), 64% (7/11) and 45% (5/11) respectively. One patient had an early miscarriage at age 48 following repair and has not conceived again since. One patient underwent a second repair and is awaiting further investigations. Two patients have not yet conceived following repair, one of which had sickle cell disease, age factor and endometriosis.

Our findings suggest a positive correlation between surgical repair of the niche and live births. However, this could be due to a strict selection criteria in a small sample size. In the two patients that did not have live births following repair, other factors of subfertility such as age, male factor and comorbidities could also play a role.

Limitations, reasons for caution: The small sample size can lead to selection bias and impairs the external validity of our findings. The likelihood of random error is high. Lack of a control group prevents any comparisons.

Furthermore, all repairs were performed by the two surgeons which introduces operator bias. Outcome assessors were not blinded.

Wider implications of the findings: Subfertility secondary to niches is likely to be a growing challenge as caesarean section rates continue to increase. Our study suggests that surgical repair may improve live birth rates. We present our findings to augment the current international data on live birth rates following niche repair.

O-055 Efficacy of Laparoscopic Abdominal Cerclage in Women With Prior 2nd Trimester Losses/Preterm Birth: Perinatal Outcomes of Case Series

E. Pabuccu[1], R. Pabuccu[2], G. Israfilova[3], A. Valadova[4]

[1]*Ufuk University School of Medicine, Obstetrics and Gynecology, Ankara, Turkey*
[2]*Ufuk University School of Medicine, Department of Obstetrics and Gynecology, .Ankara, Turkey*
[3]*Centrum Clinic Women's Health and IVF Center, Obstetrics and Gynecology, Ankara- Turkey, Azerbaijan*
[4]*Private Cagsu Hospital, Obstetrics and Gynecology, Düzce, Turkey*

Study question: What is the efficacy of laparoscopic abdominal cerclage (LAC) that placed during periconceptional period in singletons with prior 2nd trimester pregnancy losses/preterm deliveries (PTDs)?

Summary answer: LAC seems to prolong pregnancy duration and enhance perinatal outcomes in singletons prior 2nd trimester losses/PTDs.

What is known already: Cervical insufficiency (CI) is defined as the inability of the uterine cervix to retain a pregnancy till term without the signs and symptoms of clinical contractions ,with an incidence up to 1% (Berghella, 2011). Cervical cerclage (CC) has been proposed as an effective treatment for CI in terms of successfully prolonging the pregnancy period and improving the perinatal prognosis. The common clinical approach is transvaginal cervical cerclage (TVC), which is a feasible and relatively easy technique. However, some group of women may experience late abortions and/or PTD and LAC has been proposed to enhance pregnancy outcomes.

Study design, size, duration: Case series consisting of singletons with at least 2 prior PTDs and managed with LAC was reviewed between January 2019-November 2022. After placement of LAC, reproductive and perinatal outcomes of women were reviewed for 2 years.

Participants/materials, setting, methods: All women with at least 2 prior 2nd trimester losses and/or PTDs were offered to LAC procedure during the period. After having informed consents, total of 28 LAC procedures were performed. All surgeries were performed by a single experienced laparoscopist in the same center. Non-absorbable mersilene tape was placed during preconceptional period. Reproductive outcomes including spontaneous and assisted conception cycles and perinatal outcomes were reported.

Main results and the role of chance: A total of 28 LAC proceudres were performed during the period. Mean age of women was 34 ± 2 and mean numbers of previous 2nd trimester losses/PTDs was 2.8 ± 0.8, of which all of them were <24 weeks. Total of 8 women have had gynecologic surgery in their history. Less than 12 months interval, 19 out of 28 women got pregnent; 13/28 conceived spontaneously and 6/28 conceived with after IVF treatment.

For the perinatal outcomes; there were no single case of 2nd trimester losses/PTDs <24 weeks in the entire cohort.

15 women delivered >34 weeks and remaining 4 delivered at term (>37 weeks).

During the gestation, no additional medication was provided to pregnants such as progesterone treatment.

The mean gestational age was 35 4/7 weeks.

There were no remarkable adverse events during the pregnancy. All newborns were healthy without remarkable issues, only 2 infants required intensive care for less than 2 weeks.

Limitations, reasons for caution: Small sample size, lack of a control group and randomization and heterogenious patient population.

Wider implications of the findings: LAC appears to have favorable pregnancy outcomes in singletons with prior pregnacy losses and/or PTDs. To precisely conclude, randomized controlled trials are needed with different intervention arms in the same population.

Trial registration number: non applicable

Study question: Are there a morphological features measured in coronal plane obtained by tridimensional transvaginal sonography (3D-TVS), associated with euploid blastocyst implantation?

Summary answer: Mean laeral angle (mLA) below 143 degrees was associated with lower clinical pregnancy rate among 47 euploid blastocyst transfers.

What is known already: The ESHRE/ESGE 2013 consensus on uterine malformation clustered in Class U1 (namely Dysmorphic uterus): T-shaped uterus (class U1a), uterus infantilis (Class U1b) and Class U1c including other minor abnormalities. Diagnostic criteria are still under major debate, however a few studies report an association between dysmorphic uterus and impaired fertility outcomes. In the literature, no evidence has been published on a selected population of euploid blastocyst transfers. Moreover, sonographic predictors of successful transfer in patients with dysmorphic uterus undergoing ART are not available.

Study design, size, duration: Cohort study involving 122 infertile couples undergoing ICSI with NGS-based PGT-A on trophectoderm biopsies between July-2022 and December-2023. A 3D-TVS was acquired in the luteal phase before starting ovarian stimulation. The primary outcome was to assess whether uterine morphological features associate with clinical pregnancy rate, defined as an ultrasonographic evidence of a gestational sac with fetal heartbeat per transfer. To date, 47 patients underwent vitrified-warmed single euploid blastocyst transfer.

Participants/materials, setting, methods: Uterine morphology was assessed in a coronal plane. Following measurements, we registered: (1) the distance between the two internal tubal ostia, (2) the width of the uterine cavity at corpus-isthmic level, (3) the lateral angle between the corpus-isthmic cavity, (4) the lateral indentation. The optimal cut-off values of mLA was evaluated with ROC curve; $p < 0.05$ was considered statistically significant. SPSS version 25.0 was used for statistics.

Main results and the role of chance: Median age was 38 (IR:26-43). The main cause of infertility was tubal/ovulatory in 22 cases (46%), severe male factor in 18 (39%) and idiopathic in 18 (39%). Thirteen women (28%) experienced a previous miscarriage, and half of them were submitted to a uterine cavity revision. The mLA ranged from 126 to 180 degrees (median:156 degrees), whereas mean indentation ranged from 0 to 7.2 mm (median: 3.0 mm). The patients were categorized in 2 groups by the optimal cutoff

value of mLA calculated based on ROC curve analysis. Dysmorphic uterus was defined in case of mLA (mean between right and left lateral angle) below 143 degrees (sensitivity 90%, specificity 54%; AUC=0.67). mLA levels were higher than this threshold in 37 women (80%). Relative risk to have a clinical pregnancy was 0.35 (95%CI 0.15-0.83) in dysmorphic uterus. Two women (25%) got pregnant in dysmorphic uterus group compared to 18 (72%) in normal uterus (p:0.026). After adjusting blastocyst quality and day of transfer, mLA association with a clinical pregnancy remained significant (RR 7.38, 95%CI 1.09-50.18 p = 0.04, Post hoc power: 65.3%).

Limitations, reasons for caution: Preliminary results. A larger sample is required to confirm these data.

Wider implications of the findings: The strength of the study is the definition of the impact of a dysmorphic uterus in IVF cycles with PGT-A. If confirmed in larger multicenter datasets, these data may select patients who could benefit from hysteroscopic metroplasty.

Trial registration number: not applicable

O-057 Prevalence of T-shaped uterus among women undergoing fertility treatments based on ESHRE/ESGE and Congenital Uterine Malformation by Experts (CUME) criteria.

A. Bilgory[1], Y. Atzmon[1], N. Aslih[1], Y. Shibli[1], Abu Raya[1], M. Sharqawi[1], M. Shavit[1], E. Shalom-Paz[1]

[1]The Ruth and Bruce Rappaport School of Medicine- Technion- Haifa- Israel., Hillel Yaffe Medical Center- IVF unit., Hadera, Israel

Study question: What is the prevalence of a T-shaped uterus among women undergoing fertility treatments based on ESHRE/ESGE (Grimbizis et al.,2013) and CUME (Ludwin et al.,2020)?

Summary answer: The prevalence of T-shaped uterus was 4.1% according to the ESHRE/ESGE, and according to the CUME, 1.1% T-shaped uterus and 0.9% borderline T-shaped uterus.

What is known already: The definition of a T-shaped uterus by the ESHRE/ESGE consensus (Grimbizis et al., 2013) was based on three-dimensional ultrasound (3D-US) images, defining it as a narrow uterine cavity caused by thickened lateral walls with a ratio of two-thirds uterine body and one-third cervix. This definition is subjective and therefore makes giving an objective diagnosis difficult. The CUME group (Ludwin et al., 2020) described practical diagnostic criteria for a T-shaped uterus according to 3D-US images. As there is no consensus regarding the definition, the overall prevalence according to different studies varied from 0.2 to 10.0%.

Study design, size, duration: A retrospective cohort study with prospective analysis of 3D-US images was conducted. All women who were admitted to our unit for fertility treatments and underwent 3D-US between 12/2017-12/2021 were included. Women were grouped according to infertility type. All 3D-US images of uteri suspected to be T-shaped according to ESHRE/ESGE were assessed according to the CUME criteria, based on the following three measurements: lateral indentation angle $\leq$130°, lateral indentation depth $\geq$7 mm, and T-angle $\leq$40°.

Participants/materials, setting, methods: The study was conducted in a single university-affiliated hospital. Women who underwent fertility treatments due to various indications were included. The exclusion criteria were women undergoing fertility preservation, egg donation and oocyte recipients. All 3D-US were performed by well-trained ultrasound technicians. We first screened all images and calculated the prevalence of T-shaped uteri in our population based on the ESHRE/ESGE consensus. Next, we performed the three measurements according to the CUME criteria.

Main results and the role of chance: Altogether 451 women were admitted to our fertility unit. Nine cases were excluded due to unsatisfactory 3D-US images because of technical difficulties. Finally, 442 women were included in the study and divided into in the following groups: anovulation 10.6% (n = 47), mechanical factor 11.1% (n = 49), male factor 38.7% (n = 171), and unexplained infertility 39.6% (n = 175).

The prevalence of T-shaped uterus according to the ESHRE/ESGE was 4.1% (n = 18). Among them, 3.2% (n = 3) were from the female factor groups (anovulation + mechanical), 4.1% (n = 7) from the male factor group, and 4.6% (n = 8) from the unexplained infertility group.

Afterwards, the 3D-US images were analyzed according to the CUME criteria. T-shaped uterus was defined when all three criteria were met, and borderline T-shaped uterus was defined when two out of three criteria were met. According to CUME criteria, the prevalence of T-shaped uterus was only 1.1% (n = 5), three being from the male factor group and two from the unexplained infertility group. No T-shaped uteri were found in the female factor groups. Additionally, 0.9% (n = 4) were considered borderline T-shaped.

Limitations, reasons for caution: The ESHRE/ESGE consensus is subjective and may lead to either under- or over-diagnosis. On the other hand, the CUME criteria are objective and well-defined, but due to their strictness, dysmorphic uteri with very narrow uterine cavities and thickened lateral walls may not be diagnosed as T-shaped uteri.

Wider implications of the findings: Diagnosis and management of women with T-shaped uteri are very controversial topics. Therefore, making the diagnosis more precise and objective can help us to screen for the most significant cases and tailor the management accordingly. The similar prevalence among different infertility groups reflects the incidental nature of this diagnosis.

O-058 Metabolism, histone modification and early embryo development

J. Li[1]

[1]Center for Reproductive- Women and Childen' s Hospital of Chongqing Medical University, Chongqing Key Laboratory of Human Embryo Engineering, Chongqing, China

Cellular metabolism provides fundamental components for chromatin dynamics and epigenetics. However, metabolic features, and their impact on epigenetic remodeling during mammalian pre-implantation development, remain poorly understood. In this study, we established the metabolic landscape of mouse pre-implantation embryos from zygote to blastocyst, and quantified their absolute carbohydrate metabolites. We found that amino acid/carbohydrate/lipid metabolism increased during pre-implantation development, whereas nucleotide metabolism increased at the 4- and 8-cell stages. We further demonstrated that oxidized nicotinamide adenine dinucleotide (NAD^+) is indispensable for mouse pre-implantation development. Mechanistically, NAD^+ avoids excessive minor zygotic gene activation (ZGA) by cooperating with deacylase SIRT1 to remove zygotic H3K27ac. In human, NAD^+ supplement can promote the removal of zygotic H3K27ac and benefit preimplantation development. Our findings demonstrate that precise and timely regulation of minor ZGA is controlled by metabolic dynamics, and enhance our understanding of the metabolism of mammalian early embryos.

O-059 ntermetabolites of cholesterol synthesis in granulosa cell and oocyte aging

C. Liu[1], D. Lijun[1], S. Haixiang[1]

[1]Nanjing Drum Tower hospital, Center for Reproductive Medicine and Obstetrics and Gynecology, Nanjing, China

With the development of society, there has been a significant delay in female fertility and an increasing desire for childbearing among females of advanced

maternal age in recent decades. Nevertheless, women over 35 years old have more risk of infertility and miscarriage compared to young women, due to decreased oocyte quality. These changes are mainly caused by meiotic defects, especially aneuploidy. Therefore, exploring the mechanisms of aging-related meiotic defects and aneuploidy in oocytes is of great significant for improving the pregnancy outcomes of aged women.

Oocytes are enveloped by granulosa cells (GCs) to form follicles, which constitute the reproductive units in ovaries. GCs form a metabolic community with oocytes for oocyte growth and maturation. Numerous studies have reported that metabolic coupling between GCs and oocytes could affect the process of oocyte meiosis resumption, spindle assembly, and chromatin arrangement. Maternal aging is related to disruption of oocyte-GC interactions that leads to disorders of the oocyte meiotic process. Therefore, abnormal metabolic coupling between GCs and oocytes is an important reason for decreased quality in aged oocytes.

To further clarify the metabolic coupling changes between GCs and oocytes during ovarian aging, we systematically characterized the dynamic changes in the overall transcriptomic landscapes of oocytes and GCs from young and aged mice throughout oocyte meiosis (during the growing oocyte [GO], full-grown oocyte [FGO], metaphase I [MI] oocyte [MIO], and metaphase II [MII] oocyte [MIIO] phases). Data revealed that the mevalonate (MVA) pathway, an essential metabolic pathway that uses acetyl-CoA to produce cholesterol and isoprenoids, was specifically highly expressed in GCs with the resumption of oocyte meiosis, and the expression of MVA pathway in GCs decreased with age. Atorvastatin-mediated inhibition of MVA metabolism in GCs decreased the first polar body extrusion (PBE) rate, and increased oocyte meiotic defects and aneuploidy in young cumulus-oocyte complexes (COCs). Further studies showed that the effect of the MVA pathway on oocyte meiosis was mainly regulated by protein isoprenoylation mediated by the inter-metabolites of cholesterol synthesis. Importantly, upregulation of the MVA pathway in aged GCs could ameliorate the depletion of ovarian reserve, decrease oocyte meiotic defects, and improve oocyte quality.

In conclusion, metabolite in granulosa cell is an important factor determining the oocyte quality; MVA pathway in GCs is a critical regulator of meiotic maturation and euploidy in oocytes, and age-associated MVA pathway abnormalities contribute to oocyte meiotic defects and aneuploidy; Supplementation of inter-metabolites of cholesterol synthesis is a new therapeutic target for clinical intervention to improve oocyte quality.

P-313 Dysregulation of endometrial stromal serotonin homeostasis impairs decidualization in patients with recurrent implantation failure via phosphatidylcholine metabolism

X. Sheng[1], J. Tian[1], G. Yan[1], H. Sun[1]

[1]*Nanjing University Medical School, Nanjing Drum Tower Hospital, Nanjing-Jiangsu, China*

Study question: Does abnormal serotonin homeostasis contribute to impaired endometrial decidualization in patients with recurrent implantation failure (RIF)?

Summary answer: Abnormal serotonin homeostasis in patients with RIF, which is accompanied by decreased expression of monoamine oxidase (MAO), affects decidualization of endometrial stromal cells.

What is known already: Previous studies have found that the expression of MAO, which metabolizes serotonin, is reduced in the endometrium of patients with RIF, and serotonin can induce disruption of implantation in rats. However, whether abnormal serotonin homeostasis leads to impaired decidualization in patients with RIF and the mechanism remains unclear.

Study design, size, duration: Endometrial samples from 31 patients with RIF and 31 fertile patients were used to investigate the expression levels of MAOA, MAOB, and serotonin. We isolated human endometrial stromal cells to investigate the role of MAOA, MAOB and serotonin in inducing decidualization in vitro and further explored the mechanism using RNA-seq and LC/MS analyses.

Participants/materials, setting, methods: The levels of serotonin in the endometrium of patients with RIF were detected by ELISA and immunohistofluorescence, and the key genes of abnormal serotonin metabolism were analyzed combined with single-cell sequencing data. The effects of MAO on the decidualization of stromal cells were investigated using human endometrial stromal cells in vitro induced decidualization model and mouse artificially induced decidualization model. The potential mechanisms of MAO regulating decidualization were explored by RNA-seq and LC/MS analysis.

Main results and the role of chance: We found that women with RIF have abnormal serotonin metabolism in the endometrium and attenuated MAO in endometrial stromal cells. Endometrial decidualization was accompanied by increased MAO in vivo and in vitro. Attenuated MAO caused increased local serotonin content in the endometrium, impairing stromal cell decidualization. RNA-seq and LC/MS analyses showed that abnormal lipid metabolism, especially phosphatidylcholine metabolism, was involved in MAO-deficiency induced defective decidualization. Furthermore, decidualization defects were rescued by phosphatidylcholine supplementation.

Limitations, reasons for caution: This study found that impaired serotonin metabolic homeostasis and abnormally reduced MAO expression were one of the reasons for repeated implantation failure. However, the source and other potential function of serotonin in the endometrium remain to be further explored.

Wider implications of the findings: This study shows new insights into the mechanisms of serotonin homeostasis in human endometrial decidualization and provides new biomarkers or targets for the treatment of patients with RIF.

P-340 Endometrial microbiome - is every dysbiosis an inflammation?

E. Morawiec[1], A. Bednarska- Czerwinska[2], M. Czerwinski[2], A. Pudelko[1], A. Strychalska[1], M. Borowiec[1]

[1]*Gyncentrum Clinic, Genetic Laboratory, Katowice, Poland*
[2]*Gyncentrum Clinic, Gyncentrum Fertility Clinic, Katowice, Poland*

Abstract: Study question: The endometrial microbiome, in addition to other parameters of inflammation (CD138 presence, NK bright fraction presence), may be a complementary marker of ongoing local inflammation.

Summary answer: Presented results of the microbiome in comparison with the CD 138 marker may indicate inflammation in the endometrium, which is caused by dysbiosis.

What is known already: The study of the microbiome and the assessment of its impact on female reproductive system on embryo implantation, pregnancy maintenance and the success of the in vitro fertilization (IVF) procedure is an increasingly popular research topic. The protective role of *Lactobacillus* (other than *L.iners*) is known, and probably its low number may be related to the impossibility of embryo implantation. Dysfunctional mycobiome may be the cause of chronic inflammation of the endometrium, including

endometriosis and recurrent implantation failures. Importantly, the dysbiotic profile of the endometrial microflora often does not cause any clinical symptoms.

Study design, size, duration: The clinical study included 182 women in child-bearing age, who were patients of the Gyncentrum Clinic (Poland), and who were qualified for the IVF procedure. In this group of patients, 201 samples combined were tested, obtaining 19 negative results due to the low quality of swabs, and the small amount of microbiota impossible to efficiently isolate. In the study, samples were analysed from January to December 2022 collection.

Participants/materials, setting, methods: To analyze the assumed parameters, patients treated at the Gyncentrum Clinic underwent a routine hysteroscopy procedure, during which endometrial swabs (determination of the molecular microbiome using the Next Generation Sequencing NGS method) and tissue fragments (determination of CD138 immunohistochemically and NK fractions by flow cytometry) were collected. Nucleic acids were isolated from the swabs for the preparation of libraries, based on the Illumina-16S Metagenomic Sequencing Library Preparation.

Main results and the role of chance: The microbiome study and other inflammation parameters in the group of our patients allowed us to observe some trends. Due to the microbiological endometrium profile, the patients were divided into 3 groups: 1) normal microflora (domination of *Lactobacillus* other than *L.iners* and/or *Bifidobacterium*;n =135), 2) moderate dysbiosis (presence of *Lactobacillus* and/or *Bifidobacterium* and/or *L. iners*-max. 50 % of all sample- and also other potentially harmful species e.g. *Enterobacteriaceae* group, *Streptococcus* group, *Veilonella*;n =28); 3) dysbiosis (with/without low number of *Lactobacillus* and *Bifidobacterium*, strong dominance of harmful species listed above or *L.iners* dominance;n =19). We observed that in the group of endometrial dysbiosis patients, an increased CD138 index ($\geqslant$1/10 high power fields HPF) is more often noted - in the group of dysbiotic patients with CD138 = 0/10 HPF 7.21 %, in the group of dysbiotic patients with increased CD 138 15.49 %. We didn`t notice any trends comparing the results of CD138 to the NK bright fraction (CD56 + +/CD16-) tested in endometrial specimens, or the relationship of this fraction to the microbiome. Observed trend indicates a certain relationship in the presence of abnormal microflora and inflammation expressed by CD138, but it requires confirmation on a larger study group and obtain information about the success of pregnancy.

Limitations, reasons for caution: The conducted research require broader analysis on a larger group of patients. It is necessary to obtain full information about the success of pregnancy in all analyzed patients. Identification of taxa using the NGS method is not the same as the identification of microorganisms living in the studied microenvironment.

Wider implications of the findings: Presented results should be treated as a starting point for further analyses, important in the context of research based on infertility, focusing on relationships between the microbiome and the IVF effectiveness. It seems interesting to extend the molecular study of the microbiome to its other elements - viruses, fungi, protozoa.

P-342 Uterine contractile patterns in adenomyosis patients normalize under hormonal contraception use: the WAVES study

C. Klaassen[1], C. Rees[1], Y. Huang[2], S. Thomas[1], A. de Boer[1], B. Zizolfi[3], V. di Foreste[3], A. di Spiezio Sardo[3], N. Christoforidis[4], H. van Vliet[1,5], M. Mischi[2], B. Schoot[1,5]

[4]*Embryolab Fertility Clinic, IVF Unit, Thessaloniki, Greece*
[5]*University Hospital Ghent, Department of Reproductive Medicine, Ghent, Belgium*

Abstract: Study question: Comparison of uterine contractility (UC) in adenomyosis patients (AP) with and without hormonal contraception (HC) compared to controls with HC, measured by transvaginal ultrasound (TVUS).

Summary answer: AP with HC show better contraction coordination compared to untreated AP. AP with HC show comparable UC compared to controls with HC.

What is known already: Adenomyosis is a disease of the uterus that can cause dysmenorrhoea, menorrhagia, dyspareunia and subfertility. These symptoms could be explained by the different contraction patterns in women with adenomyosis compared to healthy controls. Therapeutic use of hormonal contraception reduces the symptoms experienced by women with adenomyosis. This could be explained by the normalization of contraction patterns, which has not yet been objectively quantified due to the absence of a suitable measurement tool. A novel speckle-tracking and strain analysis by 2D TVUS recordings has recently been used to assess differences in contraction coordination, contraction frequency, velocity and direction in healthy women.

Study design, size, duration: This study is part of an ongoing multi-centre prospective observational cohort study investigating UC on TVUS. Our study includes the TVUS recordings of 23 women with adenomyosis without hormonal contraception treatment, 15 women with adenomyosis undergoing hormonal contraception treatment, and 17 women with healthy uteri undergoing hormonal contraception treatment. Patients were included in 3 centres from 2017 to 2023 (Catharina Hospital Eindhoven, Fertility Clinic Thessaloniki and University Federico Napels).

Participants/materials, setting, methods: 23 women with sonographic suspicion of adenomyosis without HC, 15 women with adenomyosis undergoing HC treatment and 17 women with healthy uteri with HC were included. HC included oral combined HC, progesterone only pill and hormonal IUD. UC frequency, amplitude, velocity and coordination were assessed by applying a dedicated speckle-tracking and strain analysis to 2-4-minute TVUS recordings in midsagittal section. AP with HC were compared to AP without contraception and to healthy controls with HC.

Main results and the role of chance: Age, BMI, parity and uterus volume were significantly higher in the women with adenomyosis compared to the healthy controls ($p < 0.05$). The adenomyosis group with contraception showed more contraction coordination compared to the adenomyosis group without hormonal contraception treatment (0.23 $\pm$0.10 vs. 0.29 $\pm$0.11, $p = 0.041$). There was a tendency towards higher contraction frequency (1.53 $\pm$0.21 vs. 1.42, $p = 0.153$) and lower amplitude (0.56 $\pm$0.04 vs. 0.65 $\pm$0.04, $p = 0.159$) in the adenomyosis group with hormonal contraception treatment compared to the adenomyosis group without hormonal contraception treatment. There were no significant differences in uterine contractility between the adenomyosis group with hormonal contraception treatment compared to the healthy group with hormonal contraception treatment.

Limitations, reasons for caution: No sub-analysis was done to assess effects of additional adenomyosis and contraception characteristics due to this being an ongoing study. Women with extensive adenomyosis were not included due to impossibility to perform analysis of ultrasound recordings. AP were older, had higher BMI and larger uterus volumes than healthy controls.

Wider implications of the findings: The normalization of UC under therapeutic use of HC compared to untreated AP and the lack of differences in UC between AP and healthy controls with HC, confirms the therapeutic effect on adenomyotic symptoms. This presents a new therapeutic efficacy marker for adenomyosis.

[5]*Baylor College of Medicine, Adjunct Clinical Professor, Houston, U.S.A*
[6]*Harvard University, Beth Israel Deaconess Medical Center, Boston, U.S.A*
[7]*University of Valencia, Obstetrics & Gynecology, Valencia, Spain*

Study question: Does pET following ERA increase pregnancy (PR), ongoing pregnancy per transfer (OGPR) and live birth rates (LBR) in patients with ≥ 1 previous failed transfer?

Summary answer: In this group of patients, pET guided by ERA obtained a significantly higher PR, OGPR and LBR versus standard embryo transfer.

What is known already: pET consists of synchronizing embryo transfer with the optimal endometrial receptivity status of the patient by the transcriptomics identification of her personalized window of implantation (WOI). Controversial results have been published regarding the clinical usefulness of this precision medicine diagnosis in a range of clinical indications. Here we present data from patients with ≥ 1 previous failed transfer undergoing pET guided by ERA.

Study design, size, duration: Multicenter retrospective study involving 526 patients with at least one previous failed embryo transfer (ET) between 2017 and 2021. These patients were divided into two groups: cases (pET guided by ERA) (n = 385), or controls (standard blind ET) (n = 141). Clinical outcomes compared were PR, OGPR and LBR for each group.

Participants/materials, setting, methods: Age, body mass index (BMI), previous failed attempts, proportion of embryos with PGT-A and transferred embryo quality were compared between the two groups. ERA test was performed in HRT cycles and subsequent embryo transfer was carried out replicating the same conditions and following the recommendation given for pET. Standard ET was also performed in HRT cycles. Wilcoxon rank sum test was applied to quantitative comparations. Chi-square test was done for categorical variables.

Main results and the role of chance: In this retrospective analysis, age and number of previous failed ET was higher in the ERA group ($p < 0.05$). Clinical results in terms of PR, OGPR and LBR were significantly higher when pET guided by ERA was performed when compared to the non-ERA group.

	pET guided by ERA	Standard embryo transfer	p-value
Number of patients	385	141	-
Age (mean ± SD)	36.21 ± 4.94	34.54 ± 3.40	0.0007*
BMI (mean ± SD)	23.10 ± 3.18	23.07 ± 3.38	0.67
Previous failed attempts (mean ± SD)	2.51 ± 1.73	1.89 ± 1.42	0.0000026*
Embryo Quality ICM (%)			0.59
Optimal (A+B)	87.5%	85.6%	
Suboptimal (C+D)	12.5%	14.4%	
Embryo Quality TE (%)			0.6
Optimal (A+B)	72%	74.43%	
Suboptimal (C+D)	28%	25.57%	
Embryos with PGTA (%)	200/385 (51.95%)	70/141 (49.65%)	0.64
PR (%)	227/385 (58.96)	64/141 (45.39)	0.007*

(continued)

Continued

	pET guided by ERA	Standard embryo transfer	p-value
OGPR (%)	168/385 (43.64)	47/141 (33.33)	0.042*
LBR (%)	161/378 (42.59)	45/139 (32.37)	0.045*

*Significant different ($p < 0.05$).

Limitations, reasons for caution: This is a retrospective study, having limitations of its nature.

Wider implications of the findings: These results show that pET guided by ERA in patients with ≥ 1 failed transfers increased significantly PR, OGPR and LBR versus standard blind ET.

O-060 Single-cell DNA sequencing reveals that current bulk DNA sequencing methods lead to an underestimation of chromosomal mosaicism in human blastocysts

E.A. Chavli[1], S. Klaasen[2], D. Van Opstal[3], J. Laven[1], G. Kops[2], E. Baart[1]

[1]*Erasmus MC, Division of Reproductive Medicine- Department of Obstetrics and Gynecology, Rotterdam, The Netherlands*
[2]*Hubrecht Institute-KNAW and University Medical Centre Utrecht, Hubrecht Institute-KNAW and University Medical Centre Utrecht, Utrecht, The Netherlands*
[3]*Erasmus MC, Department of Clinical Genetics, Rotterdam, The Netherlands*

Study question: What is the incidence of chromosomal mosaicism in trophectoderm and inner cell mass from good quality human blastocysts after NGS-based single-cell molecular karyotyping?

Summary answer: Single-cell analysis showed that almost all human blastocysts are mosaic, involving low level mosaicism and/or abnormal cells resulting from reciprocal error events.

What is known already: Chromosome segregation in early human embryos is considered to be error prone. While meiotic errors affect all cells within embryos, mitotic errors lead to chromosomal mosaicism, the presence of cytogenetically different cells within an embryo. The reported incidence of mosaicism in blastocysts after bulk DNA sequencing of multicellular trophectoderm (TE) biopsies performed for preimplantation genetic testing for aneuploidy (PGT-A) varies between 2-19%. However, bulk DNA analysis can only assess net average chromosome gains or losses with a detection limit of 20-30%, and it makes distinguishing true mosaicism from technical artefact problematic.

Study design, size, duration: Observational study in human good quality surplus embryos which were donated for research purposes (CCMO, NL82597.000.22). The embryos were thawed and cultured until the blastocyst stage. From the blastocysts with at least a morphology grade 3BB, the ICM was dissociated from the TE. From 55 embryos, both samples were successfully disaggregated into single cells and manually placed in 384 well plates. For the cytogenetic analysis, a validated method for single-cell molecular karyotyping was used (scKaryo-seq).

Participants/materials, setting, methods: Embryos with at least two cytogenetically different cells were considered mosaic. To investigate if bulk DNA sequencing would have detected this mosaicism, we performed an *in-silico* reanalysis on our single-cell data. For each embryo, TE cells with the same mitotic abnormality were quantified. Next, we determined the number of mosaic embryos in which these abnormalities were present in at least 20% of TE cells, as a cut-off for what PGT-A methods are expected to detect.

Main results and the role of chance: On average 42% of the total number of cells that could be isolated per embryo were successfully karyotyped, giving a total of 1057 karyotyped cells (522 normal, 535 abnormal) from 55 embryos. Six embryos (11%) were normal, four (7%) were uniformly abnormal and 45 (82%) were mosaic. From these, 14 (26%) embryos were aneuploid mosaic with cytogenetically different abnormal cells and 31 (56%) were diploid-aneuploid mosaic with normal and abnormal cells. Here cytogenetically different abnormal cells were also frequently observed, with products of reciprocal events detected in 20 embryos.

The *in-silico* reanalysis was performed on 38 embryos with a mosaic TE. It predicted that only 11% of the mitotic abnormalities observed in TE cells through scKaryo-seq would have been detected by bulk DNA sequencing. In 19 out of 38 embryos at least one mitotic abnormality affected more than 20% of the TE cells, meaning that only 50% of the embryos would have been recognized as mosaic with bulk DNA analysis.

Bulk DNA sequencing methods used for PGT-A lead to an underestimation of mosaicism, since low-level mosaicism that affects a few cells within an embryo and products of reciprocal events without a net gain or loss remain undetected.

Limitations, reasons for caution: Isolation and cytogenetic analysis of viable single cells at the blastocyst stage is technically challenging and only 42% of the cells per embryo could be successfully karyotyped. Furthermore, it is unknown to what extent in vitro culture conditions and the freezing-thawing process influenced our findings.

Wider implications of the findings: These single cell observations support the notion that mosaicism is a common biological phenomenon in human blastocysts. Any selective mechanism eliminating embryos or cells with chromosomal abnormalities is still not fully active at this stage. The underestimation of mosaicism by bulk DNA analysis has potential implications for current PGT-A practices

Study question: How does the small non-coding RNA (sncRNA) expression profile of the human embryo change from day three (E3) to seven (E7) of preimplantation development?

Summary answer: From E3 to E7, micro-RNA expression becomes more dynamic, targeting genes important for lineage segregation.

What is known already: The drivers of lineage specification [SP1] in the human embryo remain unknown. SncRNAs regulate gene expression in most biological systems studied to date, with critical roles in cell development, differentiation, and disease. The most well-studied class of sncRNA, microRNAs (miRNAs), are required for embryo development to the peri-implantation stage in animal models, and their expression regulates embryonic stem cell differentiation in vitro.

Study design, size, duration: Eighty-seven E3-E5 embryos donated for research to the CReATe Fertility Centre (Veritas IRB#16580) between 2002 and 2021 were thawed and cultured to E3-E7. A total of 1279 cells were profiled for sncRNAs. Of these, 463 had known gender and 189 cells were co-sequenced for their mRNA complement.

Participants/materials, setting, methods: Good-quality embryos by morphology were enzymatically and mechanically dissociated into single cells and subjected to small and large RNA sequencing, as outlined in Petropoulos et al. 2016 and Hagemann-Jensen et al. 2018. Gene expression was analyzed with the 'Seurat' package. MiRNA targeting and pathway analysis was performed with Mienturnet.

Main results and the role of chance: We identified the complete complement of small RNAs present in the human preimplantation embryo, with piRNAs being the most abundant in E3 and miRNAs increasing in diversity and abundance to E7. Uniform Manifold Approximation and Projection (UMAP) analysis revealed progression with developmental stage and lineage. Split-cell co-sequencing identified canonical transcriptional markers of preimplantation development, allowing the classification of the small RNA profiles of 16-cell, early blast, inner cell mass (ICM), mural TE, and polar TE populations. Enriched miRNAs in the E5 ICM included miR-302b-5p and miR-302c-3p, which have known functions in stem cell programming. Conversely, TE cells were enriched for miR-519b-3p, miR-519c-3p, and miR-516a-5p, all members of the imprinted primate-specific microRNA gene cluster (C19MC), which is required for placenta formation. Targeting analysis identified miRNA-gene networks involving the Hedgehog, Hippo, and FoxO signalling pathways, all of which are developmentally significant.

Limitations, reasons for caution: This study was performed on embryos from a single center – embryo handling and culture conditions may influence sncRNA expression. Furthermore, the ability of these embryos to implant was unknown, therefore we likely profiled some non-viable embryos.

Wider implications of the findings: The epigenomic changes which drive lineage segregation are poorly understood, and there are vast differences in embryonic development between conventional model systems and humans. We report the first sncRNA profile of single cells between human E3 and E7, providing a resource for further exploration of their role in preimplantation development.

Trial registration number: not applicable

Study question: Can microRNA expression in blastocoel fluid (BF) predict embryo implantation potential?

Summary answer: Up-regulation of miR-106, miR-373, miR-301, miR-320 and miR-525-3p represents the molecular signature characterizing the embryos with high implantation capability.

What is known already: The discovery of DNA within the BF and in spent embryo culture media, has caused increased interest in the non-invasive pre-implantation testing application for monogenic disorders and aneuploidies. Aneuploid embryos have a lower implantation potential, however, chromosomal abnormalities represent only a tiny percentage of the causes of implantation failure. MiRNAs can control all cellular pathways and are involved in pluripotency, self-renewal, and stemness, and their altered regulation affects different human diseases.

Study design, size, duration: From September 2018 to March 2022, 112 BFsampleswere collected from human embryos on the fifth day of development, before the blastocyst cryopreservation. The samples were classified according to blastocyst grade and the data on implantation outcome and term births were collected for the transferred embryos. We compared the expression profiles of 89 miRNAs, previously identified in BF, between 33 BF from implanted embryos and 30 from non-implanted ones, regardless of blastocyst grade.

Participants/materials, setting, methods: By custom-designed TaqMan Low-Density Array card (TLDA), we analyzed the expression of 89 miRNAs in 4 different BF samples simultaneously. Differentially expressed (DE) miRNAs were identified by Volcano plot and Significance Analysis of Microarrays (SAM) tests. Bioinformatic analysis was performed to identify the biological role of the DE miRNAs. To evaluate miRNA's ability for predicting implantation, Pearson's correlation analyses, classical univariate Receiver Operator Characteristic (ROC) curve analysis, and the optimal cut-off value determination were performed.

Main results and the role of chance: We found five miRNAs, miR-106, miR-373, miR-301, miR-320 and miR-525-3pup-regulated in BF from implanted blastocysts. The identified miRNAs perform an important role during the first phases of embryo development suggesting that their up-regulation may reflect embryo health. Moreover, four of the five miRNAs showed significant correlation coefficients in both implanted and non-implanted blastocysts, indicating that their expression changes in the same way in the single sample and reflects the potentiality of the embryo to implant. Finally, ROC curve analysis confirmed that our miRNAs could be considered potential biomarkers for implantation.

Limitations, reasons for caution: Successful implantation requires a close dialogue between the embryo and the endometrium, mediated by different proteins and miRNAs produced by both the embryo and maternal tissues. Determining the quality of the embryo and its implantation potential is not sufficient to predict successful pregnancy outcomes.

Wider implications of the findings: This study represents the first report correlating miRNA profiles in BFand implantation and suggests that miRNA signature could become an accurate tool to evaluate embryo quality. It could be associated or replaced with the PGT-A to choose the most competent embryo and improve the outcome of assisted reproduction cycles.

Trial registration number: The study has been approved by theEthical Committee of Azienda Ospedaliero Universitaria Policlinico "G.Rodolico -San Marco" Catania.

O-063 Accurate mitochondrial DNA quantification clarifies the clinical value of measuring mtDNA in trophectoderm biopsy specimens

K. Spath[1], N. Kubikova[2], H. Abdalla[3], S. Batha[3], J. Ben Nagi[4], S. Cawood[4], K. Glynn[3], P. Serhal[4], D. Wells[1]

[3]The Lister Fertility Clinic, Fertility & Reproductive Health, London, United Kingdom
[4]Centre for Reproductive and Genetic Health, CRGH Portland, London, United Kingdom

Study question: Can accurate mitochondrial DNA (mtDNA) quantification of trophectoderm (TE) biopsy specimens provide insights into the biology and viability of blastocyst-stage human embryos?

Summary answer: mtDNA quantity in TE cells is correlated with embryo morphology and shows alterations associated with aneuploidy. However, measurement does not significantly improve embryo viability assessment.

What is known already: Mitochondria are essential organelles, responsible for producing ATP. Changes in the amount of mtDNA in blastocysts biopsy specimens have been reported in association with embryo implantation potential, leading to proposals that mtDNA quantification might serve as a useful biomarker of embryo viability. However, results from clinical studies to explore this possibility have yielded contradictory data, due in part to deficiencies of the molecular methods used for mtDNA measurement. We sought to clarify what quantification of mtDNA can tell us about embryo biology and viability by developing and applying a method that we believe to be the most accurate ever devised.

Study design, size, duration: This study involved the analysis of samples collected during the course of routine preimplantation genetic testing for aneuploidy (PGT-A). The IVF treatments and embryo biopsies were undertaken at two different clinics, while chromosomal analyses were carried out at a single reference laboratory. Mitochondrial data was subsequently analysed in a university setting. The embryos analysed were derived from a broad population of patients referred for PGT-A (average age 38.7 years; range 25-47).

Participants/materials, setting, methods: 651 blastocysts from 133 couples underwent trophectoderm biopsy on day-5 or day-6. The specimens were analysed using a highly validated real-time PCR method, which was used to quantify three distinct sites in the mtDNA and 198 loci in the nuclear genome. The measurement of multiple independent loci provided outstanding sensitivity and accuracy. The nuclear loci were used to normalise the mtDNA data, adjusting for differences in the number of cells in the biopsy specimens.

Main results and the role of chance: The method developed displayed extraordinary sensitivity and accuracy when quantifying mtDNA. Lower mtDNA quantities were associated with day-6 biopsy ($p < 0.0001$), extent of blastocyst expansion ($p < 0.0001$), and superior TE morphology, although the latter was not statistically significant ($p = 0.09$). mtDNA levels were higher in aneuploid embryos ($p < 0.0001$), independent on patient age. However, the difference was not sufficient to be considered diagnostic. There was no correlation between mtDNA level and the chances of blastocyst implantation in this dataset. Lower mtDNA levels, previously reported to be associated with higher probabilities of embryo implantation, were most often observed in embryos of excellent morphological grade and likely reflect the increased TE cell numbers of such embryos. Little if any mtDNA replication occurs during preimplantation development and consequently the mtDNA content is divided amongst an ever-growing number of cells, meaning less mtDNA per cell. In this context, mtDNA quantification of blastocyst biopsy specimens provides a highly sensitive measure of TE cellularity, but probably provides little additional benefit for embryo selection beyond conventional morphological grading. However, the fact that higher mtDNA quantities were observed in aneuploid embryos, may indicate that subtle differences in TE cellularity exist in abnormal embryos, which are not fully captured by traditional morphological assessment.

Limitations, reasons for caution: Previous studies suggested that some blastocysts have greatly elevated mtDNA levels and that such embryos are not viable. In this study, only 5% of embryos were considered outliers in terms of mtDNA quantity. Unfortunately, none of these embryos were transferred, so the potential of these embryos could not be assessed.

Wider implications of the findings: The quantification of mtDNA in trophectoderm biopsies has sometimes been used for the prioritisation of embryos for transfer. While our results confirm existence of biologically interesting associations between mtDNA and aneuploidy, and a relationship with certain aspects of embryo morphology, measurement of mtDNA seems unlikely to significantly improve embryo selection.

O-064 Genome-wide analysis of meiotic recombination reveals a subset of oocytes with reduced frequency of recombination and increased risk of aneuploidy.

Z. Gunes[1], D. Wells[2]

[1]University of Oxford, Nuffield Department of Women's and Reproductive Health, Oxford, United Kingdom
[2]Juno Genetics, Clinical Genetics, Oxford, United Kingdom

Study question: Are there differences in recombination rates between male and female embryos, and is the frequency of recombination associated with the risk of aneuploidy?

Summary answer: There is more recombination in female meiosis than in males. Aneuploidy is associated with fewer recombination events. Genome-wide reduction in recombination predisposes oocytes to aneuploidy.

What is known already: Aneuploidy is believed to be the primary explanation for embryo implantation failure and miscarriage and is, therefore, of great relevance to IVF. Despite the high frequency and clinical importance of aneuploidy, the mechanisms causing a gamete to become chromosomally abnormal are only partially understood. One factor known to influence the risk of aneuploidy is meiotic recombination. An absence of recombination or atypical positioning of chiasmata predisposes to chromosomal malsegregation. Most data on the subject of meiotic recombination and aneuploidy comes from miscarriages and aneuploid births, but this provides an incomplete view since most aneuploidies are lethal at earlier developmental stages.

Study design, size, duration: ~300,000 polymorphisms scattered across the genome were genotyped in DNA from 125 couples and 543 blastocysts that they produced. The inheritance of individual alleles was tracked from parents to embryos, allowing the parental origin of each chromosome to be determined. This strategy also permitted the detection of abnormal numbers of chromosomes, allowed deduction of which meiotic division aneuploidy had arisen in, and revealed the sites of meiotic recombination on each chromosome in the embryos analysed.

Participants/materials, setting, methods: Embryo analysis involved trophectoderm biopsy, followed by multiple displacement amplification. Parental DNA and amplified embryo samples were then tested using a microarray. 22,133 individual recombination events on 14,561 chromatids were evaluated. The relationship between aneuploidy and recombination frequency was considered. The average distance between recombination events was calculated by dividing the size of each autosome (in Mega bases – Mb) by the number of detected recombination events. An unpaired t-test was conducted for statistical analysis.

Main results and the role of chance: A quarter of all embryos were found to carry one or more chromosome abnormalities (altogether, 221 chromosome abnormalities were detected). Of these, 82% had a maternal (oocyte) origin, while 18% were paternal. Chromosomes 16 and 22 were the most frequently affected by aneuploidy, together accounting for 33% of all maternal chromosome abnormalities. Analysis of recombination events in maternally and paternally inherited chromosomes confirmed that female meiosis is associated with a significantly higher frequency of recombination (41.4 ±7.7 recombination events compared with 24.4±4 in chromosomes of paternal origin). Chromosomes 21 and 22 showed the lowest number of recombination events, consistent with their small size (average of 0.6 and 0.7 recombination sites per chromosome, respectively). As expected, a complete failure of recombination occurred more frequently for chromosomes with lower numbers of recombination events. Interestingly, embryos with aneuploidies of maternal origin showed evidence that the oocytes that produced them had lower recombination rates in general (not restricted to the affected chromosomes) than those producing euploid embryos (P = 0.01). Across the genome, average distances between recombination events were ~10% lower for euploid embryos compared with aneuploid embryos (72.4 +/-14 Mb versus 81+-18 Mb) (P = 0.0004).

Limitations, reasons for caution: It is possible that the pattern and frequency of recombination sites that exist in sperm and oocytes might show some differences from the blastocysts tested during this study, considering that more than half of all oocytes either fail to fertilise or produce embryos that arrest before the blastocyst stage.

Wider implications of the findings: As expected, a higher aneuploidy rate and more recombination events were seen in female meiosis compared with male meiosis. Interestingly, aneuploidy was associated with lower levels of recombination across the whole genome, not only for the affected chromosomes, suggesting that unusually low recombination activity predisposes some oocytes to chromosome malsegregation.

O-065 A multi-center randomized controlled trial of intraovarian injection of platelet rich plasma for women with poor ovarian response

N. Herlihy[1], Y. Cakiroglu[2], C. Whitehead[1], A. Reig[1], A. Klimczak[1], R. Scott[1], B. Tiras[2], E. Seli[1]

[1]IVIRMA New Jersey, Reproductive Endocrinology and Infertility, Basking Ridge, U.S.A.
[2]Acibadem Mehmet Ali Aydinlar University, Obstetrics and Gynecology, Istanbul, Turkey

Study question: Does intraovarian injection of autologous platelet-rich plasma (PRP) improve oocyte yield in young patients with poor ovarian response (POR)?

Summary answer: Intra-ovarian PRP injection did not result in increased number of oocytes retrieved or improvement of any other relevant measured outcomes.

What is known already: POR is one of the major hurdles to overcome in patients undergoing controlled ovarian hyperstimulation (COH) for in vitro fertilization (IVF). Several methods have recently emerged to attempt follicular reactivation in these patients with a poor prognosis. One of them, the intra-ovarian injection of autologous PRP, demonstrated promising results in retrospective and prospective cohort studies.

Study design, size, duration: This was a multi-center, randomized controlled trial (RCT) to evaluate the efficacy of PRP in improving IVF outcomes in women with POR. Patients who met inclusion criteria (<38 years, two or more prior cycles with < 3 oocytes retrieved, and without single gene disorders, prior ovarian surgery, endometriomas, BMI >35, or severe male factor infertility) were randomized to either receive an autologous intra-ovarian PRP injection (PRP group) or no intervention (control group) prior to COH.

Participants/materials, setting, methods: A total of 83 patients were randomized to PRP group (n = 41) or control group (n = 42). After treatment, patients underwent COH, oocyte retrieval, intracytoplasmic sperm injection (ICSI), preimplantation genetic testing for aneuploidy (PGT-A), and single frozen euploid embryo transfer. Number of MII oocytes obtained was the primary outcome. Secondary outcomes included ovarian reserve tests (antral follicle count [AFC] and anti-Mullerian hormone [AMH]), blastocyst and euploid blastocyst yields, and sustained implantation.

Main results and the role of chance: No significant differences were observed in number of MII oocytes retrieved (3.1 ± 3.3 vs 2.8 ± 2.4 in PRP vs control, respectively; p = 0.9), blastocysts (1.3 ± 2.1 vs 1.0 ± 1.3, p = 0.8), or euploid blastocysts (0.9 ± 1.6 vs 0.8 ± 1.1; p = 0.5) per cycle. Similarly, no differences were observed in the likelihood of obtaining at least one euploid blastocyst (37 vs 45%, p = 0.4; relative risk [RR], 95% confidence interval [CI] 0.9, 0.6-1.2) or the rate of sustained implantation (29 vs 31%, p = 0.9; RR 1.0, 0.7-1.3). Pre- and post-treatment AFC in both groups (PRP: from 5.2 ± 3.2 to 7.9 ± 4.5, p < 0.0001; control: from 5.6 ± 3.3 to 6.8 ± 4.8, p = 0.02) were statistically significantly different, whereas AMH was

different in the PRP group only (PRP: 0.73 ± 0.46 to 0.99 ± 0.98, p = 0.02; control: 0.70 ± 0.59 to 0.73 ± 0.57, p = 0.59).

Limitations, reasons for caution: Oocyte retrieval took place the cycle immediately following treatment; therefore, we could not evaluate long-term effects of PRP on ovarian reserve or response. Lack of a placebo group would limit interpretability had a difference between groups been observed. The effect of PRP on patients >38 years old was not studied.

Wider implications of the findings: Intra-ovarian PRP injection did not improve reproductive outcomes by any relevant measure. Our findings do not support wide utilization of PRP to improve IVF outcomes in women with POR.

[8]*University Hospital- University of Basel, Reproductive Medicine and Gynecological Endocrinology RME, Basel, Switzerland*
[9]*Skive Regional Hospital and Faculty of Health- Aarhus University, The Fertility Clinic, Skive, Denmark*

Study question: Does administration of 2 months of transdermal testosterone prior to ovarian stimulation for IVF/ICSI increase clinical pregnancy rates in Bologna criteria poor ovarian responders?

Summary answer: Pre-treatment with 5.5mg testosterone for 2 months prior to ovarian stimulation for IVF/ICSI does not increase clinical pregnancy rates as compared with placebo.

What is known already: The role of androgens in the treatment of infertile women has been extensively investigated over the last 20 years. Early animal studies and small human studies supported a potentially beneficial role of androgen pretreatment for the management of poor ovarian responders. Still, available evidence regarding androgen administration remains inconclusive, and clinical guidelines do not support their use in infertile women, mainly due to the lack of robust evidence regarding efficacy, the small sample sizes, the lack of data regarding safety, and the lack of uniform dose and duration of testosterone pretreatment for poor ovarian responders.

Study design, size, duration: T-TRANSPORT is the first multicenter multinational superiority phase III, double-blind placebo-controlled randomized trial aiming to detect differences in clinical pregnancy rates between testosterone transdermal gel or placebo for the treatment of poor responders. A sample size of 400 women was calculated, with an interim analysis prespecified to be performed after 70% of recruitment, to determine continuation, sample size re-calculation, or early termination for futility, based on the conditional power reached (≥80%, 40-80% and <20%, respectively).

Participants/materials, setting, methods: T-TRANSPORT included women 18-43 years old from 10 centers and 4 European countries (Spain, Belgium, Denmark and Switzerland) randomized between 2015-2022. Women with poor ovarian response according to the Bologna criteria were randomly assigned 1:1 (stratified by center and age group (<36, 36-39 and ≥40 years old)) to receive either 5.5mg of transdermal testosterone or placebo for ~60 days prior to initiation of ovarian stimulation for IVF/ICSI.

Main results and the role of chance: Overall, 316 poor responders were included and 290 patients were randomized. Based on the prespecified interim analysis, recruitment stopped when 70% of the patients have completed their treatment and blinded data were analyzed. Patients were categorized as group A and Group B until the decision of the DSMB board to break the randomization code is taken.

Ovarian stimulation outcomes did not differ between groups, with a (mean ± SD) number of oocytes retrieved 3.42 ± 2.25 vs. 3.69 ± 2.72, number of MII oocytes 2.75 ± 2.06 vs. 2.83 ± 1.91 and number of embryos 1.46 ± 1.22 vs. 1.90 ± 1.92, for the comparison of Group A vs. Group B, respectively.

Clinical pregnancy rates were comparable between groups, Group A: 17.42% vs. Group B 16.30%, RR (95%CI):1.07(0.64-1.79). Analysis of the results per-age strata also failed to demonstrate significant differences between groups in women <36 (Group A:24% vs. Group B: 17.9%), 36-39 (A: 21.4% vs. B:20%) and ≥40 years old (A:10% vs. B:12.3%)

Finally, no severe adverse events were observed in any of the groups that led to treatment discontinuation. Comparison of androgenic adverse events showed differences for hirsutism A:7.10% vs. B:14.07% and acne A:16.13% vs. B:21.48%, whereas very few cases of alopecia A:1.29% vs. B:2.22% and voice deepening (A:1.29% vs. B:0%) were reported.

Limitations, reasons for caution: All patients, per protocol, underwent D3 embryo transfer.

In addition, the study duration exceeded 7 years, owing to a temporary halt during the COVID-19 pandemic.

Finally, the results presented here are blinded data which will be unblinded by the time of presentation based on the interim analysis performed.

Wider implications of the findings: Testosterone pre-treatment prior to IVF/ICSI does not increase clinical pregnancy rates in poor ovarian responders.

Planned posthoc analyses within the T-TRANSPORT trial aim to investigate whether testosterone may affect ovarian reserve markers, follicular fluid biomarkers, cumulus cells gene expression, and libido in women with poor ovarian response.

Study funding: Yes.

Funding source: Funding by commercial/corporate company(ies). The study received Unrestricted grants by Ferring Pharmaceuticals, BESINS international and Roche Diagnostics. Testosterone and placebo gel were provided by BESINS INTERNATIONAL.

Trial registration number: NCT02418572

[4]*ART Fertility Clinics, Statistics Department, New Delhi, India*
[5]*ART Fertility Clinics, Statistical Department, Abu Dhabi, United Arab Emirates*
[6]*ART Fertility Clinics, IVF Laboratory Department, Abu Dhabi, United Arab Emirates*

Study question: Does the measurement of AMH isoforms in low ovarian reserve patients improve the prediction of the number of oocytes after ovarian stimulation (OS)?

Summary answer: AMH assays measuring a broader range of AMH isoforms combined with antral follicle count (AFC) improve the prediction of oocytes collected after OS.

What is known already: Granulosa cells secrete AMH as a non-active prohormone (proAMH). After cleavage, it forms a complex (AMHN,C) which activates the receptor (AMHR2). Circulating AMH is a mixture of isoforms (proAMH, AMHN,C and other sub-fragments) after proteolysis, targeted by the monoclonal antibodies included in the AMH assays commonly used in clinical practice, potentially affecting the quantification of the hormone. Novel AMH assays include antibodies directed towards a broader range of the

molecule. They may provide more accurate and reliable results, especially important in poor responders, as results may involve clinical decisions on whether or not to proceed with OS.

Study design, size, duration: Prospective observational study measuring AMH isoforms using five different AMH assays, including 72 women with low ovarian reserve performing OS for IVF/ICSI at a tertiary referral fertility center, from February 2019 to December 2021. Low ovarian reserve was defined as AMH serum levels <1.1ng/ml (Elecsys, Roche), following Bologna criteria. All patients performed OS for IVF/ICSI with antagonist protocol.

Participants/materials, setting, methods: On day 2/3 of cycle, prior to initiating the OS, AFC, serum FSH, LH, estradiol, progesterone and AMH levels were measured using Elecsys assay (Roche). Extra serum samples were frozen at -20C for subsequent analysis, using four different AMH assays (AnshLabs, Texas): AL-196 (PCOCheck ELISA), AL-124 (PicoAMH ELISA), AL-105 (US-AMH ELISA) and AL-133 (Total Mature-AMH ELISA). Ethical approval was obtained (Research Ethics Committee-REFA033c) and informed consent was signed by all participants.

Main results and the role of chance: Patient characteristics were [Median(IQR)]: age:39(36-42)years, BMI:28.51(26.1-30.1) Kg/m2, AFC:5.5(4-7), FSH:8.23(6.4-12.5) mIU/mL, LH 6.54(4.51-8.91) mIU/mL, Estradiol: 41.18(28.47-56.44)pg/mL, AMH-Elecsys: 0.64(0.29-0.81)ng/mL, AL-196:0.64(0.39-0.99)ng/mL, AL-124:0.79(0.49-1.24ng/mL, AL-105: 0.89(0.57-1.39)ng/mL, AL-133:1.06(0.63-1.59)ng/mL. Stimulation outcomes were: follicle number on the day of trigger (Fdot):5(3-7), cumulus-oocyte-complexes (COC's):3(2-4.5) and metaphase II oocytes (MII):3(1-4).

Spearman correlation was performed between AMH assays, AFC and OS outcomes. Elecsys revealed a good correlation with the other AMH assays ($rs = 0.60$-0.63, $p<0.001$), however, it was higher among ELISA assays ($rs = 0.954$-0.993, $p<0.001$). All AMH assays showed a significant positive correlation with AFC, Fdot, COC's and MII. However, AL-196 showed the highest correlation ($rs = 0.524$, $rs = 0.615$, $rs = 0.594$, $rs = 0.595$, respectively; $p<0.001$). Different models combining one AMH assay plus AFC were created to predict COC's and MII: AFC+AL-196 revealed the best prediction (Adjusted R2=0.474[$p < 0.001$] and 0.485[$p < 0.001$], respectively) when compared to the same AMH assay alone. AUROC analysis was performed to investigate which model predicted better <=3COC's after OS. Although all models demonstrated fair values, AUROC was better for AFC+AL-196 model (AUROC:0.796), yet no significant differences were seen when compared to AUROC for AFC+AMH-Elecsys ($p = 0.39$). AFC and AMH were good predictors for COC's collected [RR(95%CI):1.49(1.11-2.04),$p<0.01$; RR(95%CI):1.26(1.13-1.49),$p<0.001$, respectively). AFC+AMH-Elecsys predicted COC's better than AFC alone (R2=0.47 vs 0.29, respectively;Performance-Score:42.56% vs 13.21%, respectively). AFC+AL-196 had the highest performance (R2=0.599;Performance-Score:90.12%).

Limitations, reasons for caution: Although clinical assessment was performed in the same centre following the same methodology, inter-observer variability for AFC is a limitation. Besides, fresh AMH serum samples were analysed using Elecsys assay, whereas frozen serum samples were shipped to Ansh Lab (Texas) for batched analysis.

Wider implications of the findings: For patients with serum AMH<1.1ng/mL, a wide range of oocytes might be expected after OS. Novel AMH assays, targeting a wider broad of the molecule, together with AFC, can be used for these patients to obtain a better prediction for clinical outcomes and anticipate very poor response.

Trial registration number: Not applicable

Abstract citation ID: dead093.082

O-068 Transdermal testosterone gel (TTG) pre-treatment duration in improving ivf outcome in patients with poor prognosis (poseidon group 3 and 4): A randomised controlled trial.

K.D. Nayar[1], G. Kaur[1], S. Sanan[1], S. Aggarwal[1], G. Kant[1], D. Nayar[1]

[1]Akanksha IVF Centre- Mata Chanan Devi Hospital, Reproductive Medicine, New Delhi, India

Study question: To compare the most effective duration of pre-treatment with transdermal testosterone gel in improving IVF outcomes using GnRH antagonist protocol in poor prognosis patients.

Summary answer: Pre-treatment with testosterone gel for 28 days had higher clinical pregnancy rate, more mature oocytes in lesser days and lower total dose of gonadotropins.

What is known already: Poor prognosis patients undergoing IVF exhibits subnormal ovarian response resulting in higher IVF cycle cancellation and lower clinical pregnancy. Amongst various adjuvants regimens use of androgen supplementation improves clinical pregnancy and probability of live birth in such patients. Androgen stimulates early stages of follicular growth, increase the number of primary, pre-antral and antral follicles. It increases FSH receptor expression in granulosa cells, in turn leading to better oocyte yield and pregnancy rate. We aim to compare the most effective duration of pre-treatment with transdermal testosterone gel in improving IVF outcomes using GnRH antagonist protocol in poor prognosis patients.

Study design, size, duration: A prospective, randomised controlled trial was carried out from 1st September 2021 to 31st August 2022 at a tertiary infertility centre in India. 100 poor prognosis patients POSEIDON group 3 and 4 (age 21-40 years, AFC <5 and AMH ≤1.2 ng/ml) were enrolled. They were randomized into 4 groups of 25 each by computer based program.

Participants/materials, setting, methods: Group 1, control received no pretreatment, Group 2, Group 3 and Group 4 received 1% TTG one actuation (12.5mg testosterone daily) for 2, 3 and 4 weeks respectively before start of ovarian stimulation. Patients received a starting dose of HP HMG dose 300 IU and dose was adjusted. Inj. Cetrorelix 0.25 mg started when lead follicle was 14 mm and Oocyte retrievals were performed 35 hours after 250 mcg r-HCG trigger.

Main results and the role of chance: All groups were comparable with regards to baseline FSH, AFC and AMH levels. Only one cycle was cancelled in control group because of lack of response to gonadotropins till day 5 of stimulation. Requirement of total days (9.68 Vz 8.95 days) and total dose of gonadotropins was significantly lower in group 4 as compared to control group 1. This showed that cases with pre-treatment of transdermal testosterone gel for longer duration, required less amount of gonadotropin (2826 IU Gp 1 Vz 2329 IU Gp 4) treatment ($p < 0.01$) and also the mean number of mature oocytes retrieved (0.80 Gp 1 Vz 3.38 Gp 4) were significantly higher ($p < 0.01$). Day 3 fresh embryo transfers were performed for all. Incidence of clinical pregnancy rate was 4.2%, 8%, 12% in group 1, 2, and 3 respectively which increased to 20% in group 4 (p-0.33). Miscarriage rate was 4.2% , 4%, 12% and 4% in group 1 ,2, 3 and 4 respectively (p-0.71). Ongoing pregnancy rate was 4% in group 1, while it was 7.7 %, 10.6 % and 19.2% in group 2,3 and 4 respectively (p-0.33).

Limitations, reasons for caution: The study was done at a single centre with small sample size, replication with more subjects and in different centers is needed. The long term effects of testosterone pretreatment requires further studies.

Wider implications of the findings: Pre-treatment with testosterone gel in poor prognosis patients improves response to gonadotrophin, reducing amount and days to complete stimulation and results in higher number of mature oocytes and improved clinical pregnancy rates. Transdermal testosterone treatment is advantageous as it is not first metabolized in the liver, convenient to the patient.

O-069 Double vs. single stimulation in young poor prognosis patients followed by a fresh embryo transfer: a randomized controlled trial.

A. Racca[1], I. Rodriguez[1], S. Garcia[1], N.P. Polyzos[1]

[1]Dexeus University Hospital- Barcelona- Spain, Department of Reproductive Medicine, Barcelona, Spain

Study question: Does double stimulation, followed by a fresh ET (DUO-STIM fresh) improve outcomes as compared with a single stimulation in young poor prognosis patients?

Summary answer: Compared to single stimulation, DUO-STIM fresh leads to significantly higher number of good quality embryos, without hindering fresh embryo transfer outcomes.

What is known already: Dual Stimulation (ovarian stimulation both in the follicular and luteal phase of the same cycle) is an innovative strategy to retrieve higher number of oocytes in a shorter time frame, thus it is particularly appealing for poor ovarian responders. Three current limitations of Dual-Stimulation are: (1) it is unclear whether outcomes of the second (luteal) wave results from the second stimulation, or a carry-over effect from previous follicular stimulation; (2) the desynchronization between endometrium and ovaries and, (3) lack of robust evidence. No previous studies explored Dual Stimulation starting from the luteal phase, and with a fresh embryo transfer (DUOSTIM-fresh).

Study design, size, duration: This study is a prospective, randomized, controlled, single-center, superiority clinical trial comparing two different ovarian stimulation protocols: a double stimulation cycle vs. a single stimulation cycle followed by fresh ET. The primary outcome was the number of good quality embryos obtained, while secondary outcomes included results from fresh embryo transfer (clinical pregnancy, miscarriage). A total of 120 women were enrolled in this study between October 2020 and October 2022, with a 1:1allocation.

Participants/materials, setting, methods: Only young (<40 years old) poor-prognosis (AMH<1.2 ng/mL) patients were recruited in the Fertility Clinic within a tertiary University Hospital. In the investigational group, DUOSTIM-fresh, the 1st stimulation was initiated in the luteal phase followed by a 2nd stimulation 5 days post first OPU, initiated in the follicular phase and a fresh ET of the best embryo generated (1st or 2nd cycle). The control group performed a follicular phase single stimulation cycle with fresh ET.

Main results and the role of chance: Overall, 107 patients were randomized, 53 in the investigational (DUO-STIM fresh) and 54 in the control arm (single stim).

DUO-STIM fresh resulted in a significantly higher number of good quality embryos as compared to single stim (difference of mean 0.81, 95% CI 0.12-1.49). The mean percentage of embryo transfer was comparable (62.3 and 51.9, respectively for double vs single stimulation). No significant differences were found for fresh embryo transfer outcomes (ongoing pregnancy rates: 24.5 and 22.2, respectively for DUO-STIM fresh vs conventional IVF).

Of interest comparisons between different stimulation cycles (A: luteal phase DUOSTIM-fresh, B: follicular phase DUOSTIM-fresh and C: single stim didn't demonstrate any significant difference in terms of ovarian response with the mean (SD) number of mature oocytes being (A: 3.3 (2.9) B: 3.4 (3.4) C: 3.5 (2.9), respectively).

Limitations, reasons for caution: Study sample size was calculated to detect differences on the mean number of good-quality embryos. Therefore, results for secondary outcomes (embryo transfer rates and clinical pregnancy rates) should be interpreted with caution as exploratory findings that warrant future investigations.

Wider implications of the findings: Although DUOSTIM-fresh results in higher number of blastocysts as compared with a single stimulation in young poor-prognosis patients, the decision of performing dual stim should be evaluated with caution considering that whether this may improve embryo transfers rate and pregnancy outcomes is still unclear. Results on Cumulative-Live-Birth-Rate are warranted.

O-070 Paternal age is associated with mitochondrial vulnerability to sperm cryopreservation

D. Turchi[1], M. Orini[2], P. Piomboni[2], A. Luddi[2], P.V. Novara[1], A.M. Luciano[3], S. Maruccia[1], M. Mignini Renzini[1], M. Dal Canto[1], J. Buratini[1]

[1]Biogenesi Reproductive Medicine Center, Istituti Clinici Zucchi, Monza, Italy
[2]University of Siena, Department of Molecular and Developmental Medicine, Siena, Italy
[3]University of Milan, Reproductive and Developmental Biology Laboratory-Department of Veterinary Medicine and Animal Sciences, Milan, Italy

Study question: Is paternal age associated with lower mitochondrial activity in fresh and cryopreserved semen?

Summary answer: Paternal age does not appear to severely compromise sperm mitochondrial activity in fresh semen but determines higher mitochondrial vulnerability to sperm cryopreservation.

What is known already: The impact of paternal age on male fertility has not been fully clarified although growing evidence suggests age-related loss of sperm quality. Mitochondrial activity has been recognized as a reliable marker of sperm functionality, reflecting motility, vitality and fertilization competence. Sperm cryopreservation has been largely utilized in fertility preservation and ART schemes, despite its potential harm on cell membranes including those of the mitochondria. The influence of advanced paternal age (APA) on sperm vulnerability to cryopreservation-induced cell damage is still not known.

Study design, size, duration: Twenty three normospermic patients, 11 of which $\leq$ 35 (non-APA) and 12 $\geq$ 42 years old (APA), provided semen samples by masturbation after 1-5 days of abstinence, between April and August of 2022. A 250µl semen aliquot was frozen. Sperm concentration, motility, vitality, morphology and mitochondrial functionality were compared in fresh semen from non-APA vs. APA patients, while motility and mitochondrial functionality were compared in thawed semen from both groups with the two-tailed Student t-test.

Participants/materials, setting, methods: Fresh and thawed semen samples were provided by patients under evaluation for couple infertility treatment in our fertility center. Semen was cryopreserved with CryoSperm (Origio) and analyzed after rapid thawing and washing/dilution in Sperm Preparation Medium (Origio). Sperm vitality was assessed with VitalScreen (FertiPro) and mitochondrial functionality was evaluated with MitoTracker Red CMXRos (Cell Signalling Technology), through the percentage of stained cells and fluorescence intensity measured in 75 spermatozoa per patient with the ImageJ software.

Main results and the role of chance: Mean ages for non-APA and APA patients were 32.6 and 45.3 years, respectively. Age groups did not differ for any of the parameters assessed in fresh semen (volume: 2.3 ± 1.1 vs. 2.6 ± 1.2mL; concentration: 58 ± 32 vs. 47 ± 20 x$10^{6/mL}$; rapid progressive motility 5 ± 5 vs. 5 ± 8%; slow progressive motility 40 ± 10 vs. 36 ± 10%; non-progressive motility 10 ± 5 vs. 10 ± 3%; immotile: 44 ± 9 vs. 49 ± 13%; normal morphology: 6 ± 3 vs. 5 ± 1%; vitality: 71 ± 8 vs. 66 ± 15%, for non-APA and APA, respectively). However, non-APA patients presented a higher percentage of spermatozoa with rapid progressive motility (5 ± 7 vs. 0%; p = 0.04) and a lower percentage of immotile spermatozoa (76 ± 12 vs. 88 ± 9%; p = 0.02) after thawing. Regarding mitochondrial functionality, no differences were observed in fresh semen from different age groups [93 ± 11 vs. 92 ± 7% stained cells; 3.33 ± 1.57 vs. 3.35 ± 1.49 (fluorescence arbitrary units), for non-APA and APA, respectively). In cryopreserved semen, however, although age groups did not differ for the percentage of stained

spermatozoa (92 ± 10 vs. 90 ± 5%), fluorescence intensity was higher in spermatozoa from non-APA patients (2.53 ± 1.63 vs. 1.76 ± 0.54; $p < 0.01$).

Limitations, reasons for caution: Our study is limited by the potential interference of confounding factors not equally distributed in age groups. The conclusions from this study must be confirmed in other patient populations with different race/genetics and habits.

Wider implications of the findings: Our study sheds light on the impact of paternal age on sperm quality, a topic highly relevant to reproductive medicine still not fully understood. We provide evidence that APA is associated with higher vulnerability of mitochondria to the stress induced by cryopreservation and its metabolic consequences.

O-071 Paternal body mass index affects early embryo development but does not impact clinical outcomes: a timelapse study of 7,656 embryos in oocyte donation cycles

A. Quintana-Vehi[1], M.J. Zamora[1], A. Pujol[2], F. Zambelli[3], I. Miguel-Escalada[4], A. Rodriguez[5], M. Popovic[3]

[1]Clinica EUGIN, Clinical embryology, Barcelona, Spain
[2]CIRH, Clinical Embryology, Barcelona, Spain
[3]EUGIN Group, Research and Development, Barcelona, Spain
[4]Clinica EUGIN, Research and Development, Barcelona, Spain
[5]EUGIN Group, Corporate Medical, Barcelona, Spain

Study question: Does paternal body mass index (BMI) affect preimplantation development and clinical outcomes in oocyte donation cycles?

Summary answer: High paternal BMI was associated with delays in early development and poorer embryo quality on day 3, but this did not adversely affect pregnancy outcomes.

What is known already: Maternal obesity is known to negatively affect preimplantation development and clinical outcomes. While oocyte competence plays a major role in early embryogenesis, male obesity has been linked to poorer semen parameters and epigenetic alterations in sperm. Such characteristics may inherently compromise preimplantation development and ultimately impair reproductive success. Only a few reports have assessed the effects of male BMI on the progression of cell divisions and embryo morphokinetic patterns. However, current findings remain contradictory, while the effects of male obesity on fertility continue to be understudied.

Study design, size, duration: This retrospective study included 7,656 embryos from 1,342 oocyte donation ICSI cycles, performed between April 2018 and December 2021 across two fertility centres. Sperm originated from the partner (n = 1087) or donor (n = 255) and was either fresh (n = 460) or frozen (n = 835). Only the first fresh (n = 1,140) or frozen (n = 202) embryo transfer (ET) was considered. Our database included 1,089 single and 238 double ETs performed at either the cleavage (n = 424) or blastocyst stage (n = 903) of development.

Participants/materials, setting, methods: Males were stratified according to BMI, based on WHO guidelines, defined as: normal weight (BMI<24.9, n = 677); pre-obese, (BMI=25.0–29.9, n = 533); and obese (BMI>30, n = 132). Patients with severe male factor and preimplantation genetic testing cycles were excluded. Univariate analyses and logistic regression were used to evaluate associations between BMI, embryo morphokinetics and clinical outcomes. Analyses were adjusted for various confounders pertaining to patient demographics, sperm and cycle parameters. A p-value of < 0.05 was considered significant.

Main results and the role of chance: Overall, obese men displayed poorer sperm motility and underwent more day 2-4 embryo transfers and freeze-all cycles, compared to pre-obese and normal weight men ($p < 0,05$). Fertilization rates were not affected by male BMI (77.0% ± 18.9 normal weight; 77.4% ± 18.1 pre-obese; 75.3% ± 19.9 obese; $p = 0.62$), also in our adjusted analysis. Several morphokinetic parameters were delayed in embryos from pre-obese and obese patients, including pronuclei fading (tPNf, $p = 0.0064$) and division timings from the 2 to 5-cell stage (t2-t3-t4-t5, $p < 0,05$). Successively, the number of good quality cleavage embryos decreased significantly with higher BMI (normal weight, 62%; pre-obese, 59%; obese, 50.8%; $p = 0.02$). In contrast, developmental events past the 5-cell stage, including time to 8-cells (t8), blastulation (tSB) and expanded blastocyst (tB) were comparable amongst the groups ($p > 0.05$). Similarly, we observed no effect of male BMI on blastocyst quality (normal weight, 70.2%; pre-obese, 73.4%; obese, 75.5%; $p = 0.06$). Despite early developmental delays, we observed no significant effects on biochemical pregnancy (normal weight, 64.7%; pre-obese 64.1%; obese, 58.7%; $p = 0.45$), ongoing pregnancy (normal weight, 60.0%; pre-obese, 58.8%; obese, 52.9%; $p = 0.35$) and live birth rate (normal weight, 41.9%; pre-obese, 42.0%; obese, 34.9%; $p = 0.27$). Our adjusted analysis corroborated these findings.

Limitations, reasons for caution: The main limitation of this study is its retrospective design, which may not account for all confounders. Moreover, lifestyle factors, such as smoking or alcohol consumption were not considered. As such, results cannot be generalized to all patient populations.

Wider implications of the findings: Obese males show lower motile sperm counts and delayed cleavage development. While these changes impaired day 3 embryo quality, they did not affect blastocyst development and quality. That translates into comparable clinical outcomes, suggesting that specific counselling is not required in obese patients.

O-072 Lack of meaningful impact of male body mass index (BMI) on reproductive outcomes measured by cumulative live birth rates (CLBR) in 80830 IVF-ICSI treatments

L. Mossetti[1], I. Hervás Herrero[1], M. Gil Julia[2], A. Navarro Gómez-Lechón[2], R.M. Pacheco Rendón[2], R. Rivera Egea[3], N. Garrido Puchalt[2]

[1]IVIRMA Rome, IVF Laboratory, Rome, Italy
[2]IVI Foundation- Health Research Institute La Fe- Av. Fernando Abril Martorell- n° 106- Torre A- Planta 1ª- 46026- Valencia- Spain., Male infertility, Valencia, Spain
[3]IVIRMA Valencia, Andrology Laboratory and Sperm Bank, Valencia, Spain

Study question: Does men's BMI influence the reproductive success measured as CLBR per embryo transfer(ET), embryos replaced(EmbR) and oocytes utilized, if female BMI is controlled?

Summary answer: Male's BMI do not affect reproductive outcomes, although obese males seem to need slightly more ET to reach the first live birth.

What is known already: Obesity is a systemic, chronic and multifactorial disease present worldwide, involving all ages, ethnicities and social classes, and associated with hormonal alterations that may lead to a decrease in seminal quality and reproductive outcomes. The exact mechanisms involved, between excess body fat and reproductive disturbances, if any, are complex and unknown. This leads us to investigate the effect of BMI on reproductive outcomes to carry out a better counseling of couples who go to a clinic for assisted reproduction treatment. The recent improvement of measuring reproductive success by cumulative rates has never been applied to many risk factors, as obesity.

Study design, size, duration: This retrospective observational multicentric study has evaluated the results from 80830 IVF-ICSI treatments, 298422 oocytes and 215357 embryos transferred performed in Spanish IVIRMA fertility clinics between January 2008 and December 2020 by couples using their own sperm sample and oocytes.

Participants/materials, setting, methods: Couples attending IVI clinics. Male BMI was categorized in: underweight (<18.5 kg/m^2) (U), normal weight (18.5-24.99 kg/m^2) (N), overweight (25-29.99 kg/m^2) (OV) and obese (≥ 30 kg/m^2) (OB) patients, and CLBR were calculated using Kaplan Meier methods, by Cox regression to control women's BMI and age, and male's age. Reproductive success was calculated by CLBR perET, EmbR and utilized oocytes until the first LB. Data were expressed as % with corresponding 95% confidence intervals.

Main results and the role of chance: After 3 ETs, CLBR per ET, were, for groups U,N,OV and OB, respectively, 47.4%(44.3-50.3), 48.1%(47.4-48.9), 47.8%(46.2-49.4) and 47.1%(44.1-49.9), increasing after 5 ETs to 64.6(59.7-69.0), 65.1%(63.9-66.2), 62.8%,(60.2-65.3) and 59.2%(54.5-63.4).

There were statistically significant differences between Obesity and Normal weight groups ($p = 0.03$), hazard ratio [HR]: -0.01 on the Cox regression adjusted by female's age and BMI, and male's age.

Considering EmbR, after 3, CLBR were 38.8%(36.2-41.26), 35.7%(35.1-36.3), 35.2%(34.0-36.4) and 33.7%(31.5-35.9), and after 6 EmbR, 62.7%(58.5-66.5), 59.8%, (58.9-60.7), 59.8%(57.7-61.8) and 58.0%(54.1-61.5), for U, N, OV, and OB respectively, with no significant differences among groups, also confirmed by the comparable results adjusted Cox regression.

Concerning CLBR per oocyte used, with 8 oocytes, results were 38.3%(35.2-41.3), 34.7%(33.9-35.4), 32.0%(30.6-33.4) and 29.9%(27.4-32.3), and after 12 oocytes used, 54.0%(50.6-57.3), 53.5%(52.7-54.3), 49.9%(48.3-51.5) and 46.8%(43.9-49.6), for the above mentioned ordered IMC groups.

Considering 16 oocytes used, results on U, N, OV and OB males were also comparable: 69.6%(65.9-72.8), 66.7%(65.9-67.5), 62.6%(60.8-64.3) and 62.1%(58.8-65.2), respectively, also confirmed by Cox regression adjusted estimates.

Limitations, reasons for caution: The retrospective nature of this study leads to biases derived from the clinical practice and the presence of missing/incomplete or imprecise data, together with the possibility of not having controlled by all possible confounding factors.

Wider implications of the findings: Different male's BMI, when controlled by main confounders, show comparable results in the number of oocytes needed, EmbR to get the first child, and, although we confirmed a minor influence on ET needed, the message is that male's weight seems not affecting reproductive outcomes in IVF/ICSI treatments.

O-073 Delta-9-THC acts on the calcium channel CatSper and alters human sperm function

L. Wehrli[1], F. Zufferey[2], M. Rossier[2], S. Nef[1], R. Rahban[1]

[1]*University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland*
[2]*Hospital of Valais, Service of Clinical Chemistry & Toxicology- Central Institute of Hospitals, Sion, Switzerland*

Study question: Do the main psychoactive phytocannabinoid delta-9-tetrahydrocannabinol (THC) and its non-psychoactive analog cannabidiol (CBD) affect human sperm function?

Summary answer: THC reduces the ligand-dependent activation of sperm-specific Ca^{2+} channel CatSper and affects human sperm functions *in vitro*.

What is known already: Marijuana (*Cannabis sativa*) is one of the most commonly used recreational drugs worldwide. Although the impact of phytocannabinoids on reproductive health has been investigated, there is no evidence of a direct effect of THC on CatSper function.

Study design, size, duration: We studied the effects of the main psychoactive phytocannabinoid, THC, its non-psychoactive analog, CBD, as well as their major metabolites on Ca^{2+} influx via CatSper in human spermatozoa. THC and CBD were selected to further evaluate their action on progesterone-, prostaglandin-, and pH-induced activation of human CatSper. The effects of THC and CBD on hyperactivation, progressive motility in viscous media, and acrosomal exocytosis were also assessed.

Participants/materials, setting, methods: The impact of phytocannabinoids on CatSper activity was investigated on sperm samples from healthy volunteers using kinetic Ca^{2+} fluorimetry. Motility assessment was performed using Computer-Assisted Sperm Analysis (CASA). Sperm penetration into viscous media was assessed using a modified Kremer test. Acrosomal exocytosis was evaluated by flow cytometry using *Pisum sativum* agglutinin-stained spermatozoa.

Main results and the role of chance: Both THC and CBD suppress natural ligand-induced calcium influx via CatSper. In particular, THC inhibits progesterone-induced Ca^{2+} influx via CatSper at pharmacologically relevant concentrations in a non-competitive manner and reduces the pH-induced activation of CatSper. In addition, THC impaired sperm hyperactivation and penetration into viscous media and induced spontaneous acrosomal exocytosis *in vitro*.

Limitations, reasons for caution: This is an *in vitro* study. Future studies are needed to test the physiological relevance *in vivo* and whether THC can disrupt human sperm function.

Wider implications of the findings: The action of THC on CatSper in human sperm might impair the fertilization process. Healthcare providers, especially fertility clinicians, should be aware of the potentially negative effects of cannabis consumption on sperm physiology

O-074 THC reduces sperm mitochondrial membrane potential, but does not affect the acrosome reaction or in-vitro embryo developmental rates.

A. Kuzma-Hunt[1], O. Davis[1], R. Sabry[1], V. Troung[1], J. Khokhar[2], L. Favetta[1]

[1]*University of Guelph, Department of Biomedical Sciences, Guelph, Canada*
[2]*Western University, Department of Anatomy and Cell Biology, London, Canada*

Study question: Does THC alter sperm function and early embryo development following in vitro fertilization with THC-exposed sperm?

Summary answer: THC reduces sperm mitochondrial membrane potential (MMP), mainly through cannabinoid receptor agonism, but does not alter the acrosome reaction or rates of embryo development.

What is known already: Cannabis is the most commonly used recreational drug among males of reproductive age. THC is the main psychoactive component of cannabis and can cross the blood-testis barrier, disrupting the endocannabinoid system (ECS) in sperm. However, the mechanisms by which THC affect sperm function and early embryo development are unclear. In sperm, endogenous cannabinoids influence the acrosome reaction and MMP, which are critical for motility, viability and, ultimately, fertilization. To date, no studies have investigated how sperm exposed to physiologically relevant doses of THC may impact in-vitro early embryo development, and cannabis use recommendations remain unclear for patients undergoing IVF procedures.

Study design, size, duration: Bovine sperm and cumulus oocyte complexes (COCs) were used as a translational model for humans. Cryo-thawed sperm was separated using a Percoll gradient and incubated for 6-hours in one of five treatment groups: control, vehicle (0.01% ethanol), low-THC (0.032μM), mid-THC (0.32μM), and high-THC (4.8μM) – concentrations equivalent to THC plasma levels following therapeutic and mid-high recreational use, respectively (Whan et al., 2006). A minimum of 30,000 sperm and 60 COCs were analyzed per group.

Participants/materials, setting, methods: Sperm were treated for 6-hours prior to all experiments. Flow cytometry using sperm ($1\text{-}2x10^6$) stained with propidium iodide (PI) and FITC-conjugated peanut agglutinin (FITC-PNA) or JC-1 was used to measure either the acrosomal reaction or MMP, respectively. COCs were aspirated from slaughterhouse ovaries and matured in-vitro for 24-hours. IVF was performed with THC-treated sperm ($1x10^6$/mL/drop) for 10-hours. Presumptive zygotes were cultured in-vitro for 8-days. Cleavage and blastocyst rates were measured 48-hours and 8-days post-fertilization, respectively.

Main results and the role of chance: Measuring PI and FITC-PNA fluorescence showed the percent of sperm that were acrosome-reacted and either alive or necrotic. There were no significant differences in acrosome-reacted sperm among groups ($n = 9$). Measuring JC-1 fluorescence showed the percentage of sperm with high MMP. Results indicate a significant reduction in sperm with high MMP (37%) following high THC (4.8μM) exposure ($p = 0.002418$, $n = 4$). No significant differences in MMP were observed among other groups. To elicit the mechanism by which THC was reducing

sperm MMP, we repeated experiments using only JC-1-stained sperm exposed to high THC treated with SR141716 and SR144528, which are CB-1 and -2 antagonists, respectively. Additional groups included: SR141716 (4.8.μM), SR144528 (4.8μM), THC + SR141716 and THC + SR144528. Results indicate a significant reduction in sperm with high MMP (38%) in the THC group (4.8μM) compared to control (51%) ($p = 0.0417$, $n = 6$), vehicle (54%) ($p = 0.0069$, $n = 6$), and SR141716 (65%) ($p < 0.0001$, $n = 6$). There were no significant differences in sperm with high MMP in THC + SR141716 or THC + SR144528 groups, indicating that THC is acting agonistically, primarily at CB1 receptors. Following IVF with THC-treated sperm, there were no significant differences in cleavage or blastocyst rates among treatment groups.

Limitations, reasons for caution: The use of bovine instead of human cells could be considered a limitation. However, as studying effects of THC-treated sperm on IVF outcomes would not be possible using human samples, it is actually an advantage. The similarity between bovine and human gametes makes bovine an ideal translational model for humans

Wider implications of the findings: As cannabis use and THC concentrations increase, this research addresses the growing concern of how cannabis impacts fertility and, ultimately, pregnancy outcome. Understanding how THC affects sperm function and embryo development will provide physicians with science-based recommendations concerning cannabis use for patients trying to conceive, pregnant, or undergoing fertility treatments.

[10]Registry of Mosaic Embryo Transfers (IRMET)

Study question: Which are the results obtained by the International Registry of Mosaic Embryo Transfers?

Summary answer: An update of clinical outcomes and post-natal results of mosaic embryos with low and high-level of mosaicism is provided.

What is known already: Chromosomal mosaic embryos are characterized by the presence of chromosomally different cell lines within the same embryo. While the transfer of these embryos is now offered as an option for women who undergo in vitro fertilization (IVF), several concerns remain. For instance, the limited data on pregnancy outcome and the possibility that intra-biopsy mosaicism in the TE is a poor predictor of the ploidy status of the ICM. Therefore, some argue that mosaicism should be not reported until a clear classification of such embryos in relation to their reproductive potential has been defined.

Study design, size, duration: We collected the clinical outcomes of 2045 mosaic embryos transferred in women who undergoing IVF between May 2019-May 2022. All embryos were cultured to blastocyst stage; trophectoderm (TE) biopsy was performed on Day-5 of development or Day6/7 for slow-growing embryos. The clinical outcomes obtained after the transfer of mosaic embryos with the different chromosomal constitutions were compared. Prenatal and post-natal outcome was collected for available cases.

Participants/materials, setting, methods: Preimplantation genetic testing for aneuploidies (PGT-A) was performed using high-resolution next-generation sequencing (NGS) methodology. TE biopsies were classified as mosaic if they had 20%-80% abnormal cells. For statistical analysis, mosaic embryos were divided into groups based on mosaic levels and chromosomal constitution detected in TE: single mosaic aneuploidy (monosomy/trisomy; SM), double mosaic chromosomes (monosomy/trisomy or combination, DM), complex mosaic aneuploidy (>2 different aneuploidies; CM) and mosaic segmental aneuploidy (single and double deletion/insertion >5Mb, MS).

Main results and the role of chance: Embryos classified as 'low-mosaic' by NGS-based PGT-A have a higher likelihood of achieving implantation compared to 'high-mosaic' embryos (48% vs. 39.%; $p < 0.05$), as well as ongoing pregnancy/live birth (40% vs. 29%; $p < 0.05$). Chromosomal composition of mosaicism abnormalities dictates the success rate of mosaic embryo transfers, with low and high segmental mosaics being preferable over low- and high-mosaics involving whole chromosomes. For 550/670 pregnancies, parental tests and post-natal data were available. The majority (99.75%) of the babies were largely healthy by routine physical inspection by neonatologists (no gross abnormalities in babies from mosaic embryos, $n = 495$). Prenatal testing performed on pregnancies from mosaic embryo transfers were generally normal. The mosaicism detected at the embryonic stage by PGT-A was reflected in prenatal testing in only 5 out of 550 pregnancies (0.9%) in which the mosaicism identified with PGT-A at the blastocyst stage was reflected in gestation by prenatal chromosomal testing as true fetal mosaicism.

Limitations, reasons for caution: Additional clinical data must be obtained to evaluate the contribution of each different chromosome before this approach can be evaluated as an additional tool to choose mosaic embryos for transfer.

Wider implications of the findings: The International Registry of Mosaic Embryo transfers continues to grow in sample size, in turn increasing the power of analysis. The findings of the mosaic embryo transfer registry can help educate the management and selection of embryos in the clinic.

[5]9.baby, GeneraLife IVF, Bologna, Italy
[6]Clinica Valle Giulia, GeneraLife IVF, Roma, Italy

Study question: Do segmental aneuploid (SA) embryos display unique morpho-kinetic patterns at early developmental stages?

Summary answer: The first three cell division cycles of embryos carrying segmental aneuploidies are significantly slower than euploid and whole-chromosome aneuploid (WCA) embryos.

What is known already: Segmental aneuploidies in blastocyst-stage human embryos prevalently originate (i.e., 70% of cases) from mitotic errors. Their clinical management is challenging because it is impossible to establish their meiotic/mitotic origin from PGT-A analysis of a single trophectoderm biopsy. Morpho-kinetic analysis based on Time-lapse microscopy (TLM) has been proposed as a valuable tool for systematic embryo evaluation, although it is unclear whether this approach alone can predict chromosomal abnormalities. This study aims to pinpoint morphokinetic patterns associated with the occurrence of segmental aneuploidies and/or mitotic errors, possibly improving DNA-based diagnostic interpretation and their clinical management.

Study design, size, duration: This is a retrospective multicenter study including a total of 7,693 embryos from 2,370 IVF cycles and 2,127 couples, cultured between 2016 and 2021 in 4 European IVF centers. Embryos with no more than 4 chromosomal alterations were considered in the analysis, resulting in 3,288 euploids, 3,155 WCA, 715 SA, and 535 complex aneuploids (CA). Overall, the dataset contained 3,742 distinct euploid-SA embryo sibling pairs.

Participants/materials, setting, methods: Standard morpho-kinetic features were annotated using various TLM systems. Blastocysts were subjected to comprehensive chromosomal screening via PGT-A. Morpho-kinetic timings across different embryo groups were compared using Kolmogorov-Smirnov (KS) test and binomial test, and associations with cleavage features were assessed via two-sided Fisher Exact (FS) test. Multi-center and center-specific logistic regression models were calibrated using a subset of data (70%), and their predictive performance was evaluated on independent test data using Area-Under-ROC curve (AUROC) metrics.

Main results and the role of chance: SA embryos cleaved at significantly slower rate than their euploid siblings in the first 3 cell cycles, from the appearance of the second blastomere t2 (average delay delta=0.49h, KS $p = 0.006$, fraction of pairs in which SA was delayed compared to euploid sibling $F = 54.2\%$, binomial $p = 0.002$) up to t8 (delta=2.16h, KS $p = 4e\text{-}4$, $F = 57.9\%$, binomial $p = 1e\text{-}8$). The developmental delay was partially compensated at full blastocyst stage tB (delta=1.71h, KS = 0.0008, $F = 57.5\%$, binomial $p = 5e\text{-}8$). SA timings also differed from WCA ones: SA embryos were significantly slower than their WCA siblings during early cell cycles, with maximum delay reached at t8 (delta=1.67h, KS $p = 0.009$, $F = 55.4\%$, binomial $p = 0.003$), but they fully caught-up at tB, with no significant difference observed. These morpho-kinetic patterns were consistently observed in each center separately, but with different effect sizes. The presence of segmental aneuploidies was significantly associated with multinucleation (OR = 1.99, FS test $p = 0.05$) and morula cell exclusion (OR = 2.69, $p = 0.006$). A logistic model based on morpho-kinetic data and cleavage features from a single center dataset and regressed against embryo aneuploidy class (euploid vs. SA embryos) displayed adequate predictive performance on independent data from the same center (AUROC=0.70), although predictivity diminished when tested on data from other centers (AUROC=0.52-0.55).

Limitations, reasons for caution: We cannot rule out inter-center variability in the annotation procedures of morpho-kinetic parameters. Standardized and automated annotation would increase the performance of predictive models and their transferability. Further work is needed to assess

whether the morpho-kinetic signal is driven by mitotic errors and if an association with clinical outcomes exists.

Wider implications of the findings: These findings might help uncovering biological events contributing to preimplantation mosaicism. Moreover, the developed predictive framework might help improving decision-making in PGT-A cycles, providing interpretation for segmental aneuploidies and possibly helping in the evaluation of embryos showing intermediate copy number values for whole chromosomes that are suggestive of mosaicism.

Study question: Following quantitative NGS for PGT-A, do current thresholds for mosaicism calling give a true reflection of the presumed mitotic origin of mosaic errors?

Summary answer: A large proportion of embryo mosaicism diagnosed following quantitative NGS-based PGT-A does not correlate with a true and expected mitotic origin, showing instead meiotic signatures.

What is known already: Mosaicism is a true biological phenomenon that can affect ongoing embryo development. However, the reproductive potential of mosaic embryos in assisted reproduction varies greatly across publications and is not fully understood. While the transfer of mosaic embryos could result in healthy live births, embryos containing meiotic errors almost never result in healthy live births. Since the clinical implications of meiotic and mitotic errors are very different, it is critical to accurately differentiate between the two. However, diagnosing mosaicism using current NGS-based PGT-A is not always accurate due to technical and biological limitations which may misclassify mosaic embryos.

Study design, size, duration: Follow-up analysis was carried out on 159 embryos previously categorised as mosaic by NGS-based PGT-A. To identify the origin of mosaic calls, SNP genotyping and karyomapping were performed on the same amplified DNA used for the clinical NGS analysis. Trophectoderm biopsy samples were obtained from embryos on days 5,6 or 7 of development from a single IVF centre between 2018-2022. For all PGT-A tested embryos, the reported mosaicism rate at the IVF centre was 12%.

Participants/materials, setting, methods: Samples were analysed using PGTai from CooperSurgical with a 30-80% CNV mosaicism range. Patients with mosaic embryos consented to karyomapping follow-up using sibling embryo reference DNA. The origin of mosaic events was defined by SNP inheritance patterns for the affected chromosome. Meiotic errors were defined by the presence of both haplotypes from one parent for trisomy, and the absence of a parental haplotype for monosomy. Mitotic errors were inferred following a result of biparental inheritance.

Main results and the role of chance: A total of 154 diploid embryos identified as mosaic by NGS-based PGT-A were re-analysed by SNP-genotyping. Of these, 30.5% (n = 47) displayed at least one error of meiotic origin following SNP genotyping.

Among the 154 embryos, 189 mosaic chromosomal abnormalities were identified. After SNP-genotyping, 30.7% of chromosomal abnormalities (n = 58) showed evidence of meiotic signatures: 52 whole-chromosome (24 gains, 28 losses), and 6 segmental errors (5 gains and 1 loss). Of 73 segmental errors detected in total, only 8.2% of them (n = 6) were identified to be of meiotic origin.

Following PGT-A, 7.8% of embryos (n = 12/154) displayed ≥3 chromosomal abnormalities in the mosaic range. Of these embryos, 58.3% (n = 7/12) displayed one or more meiotic aneuploidies. Overall, embryos showing multiple mosaic events were significantly more likely to have a least one error of meiotic origin than embryos containing one abnormality (McNemar's test p-value= 1.171e-14).

Among mosaic calls above 50% CNV, 56.7% (n = 55/97) showed evidence of meiotic origin. In contrast, but importantly, in the low-moderate mosaicism range <50% CNV, 3.3% of errors (3/92) also displayed meiotic signatures, including two whole chromosome errors (chr21 gain at 32% CNV and chr13 loss at 46% CNV), and one segmental error (dup(6)(pter-p12.1) at 33% CNV).

Limitations, reasons for caution: Since karyomapping relies on recombination events to identify meiotic trisomy, the true origin of intermediate copy-number changes cannot always be identified. Therefore, errors without recombination may be missed, potentially underestimating meiotic gains, especially segmentals. The absence of a parental haplotype cannot entirely rule-out a mitotic error from a biopsy sample.

Wider implications of the findings: Quantitative NGS methodologies are unable to accurately distinguish the origin of mosaic errors in PGT-A samples. Since the clinical impact of meiotic and mitotic errors differs greatly, this limitation could explain mosaic embryos' reduced viability. Reliable identification of meiotic aneuploidies in presumed mosaic embryos is likely to improve clinical outcomes.

O-079 Perinatal and postnatal outcomes up to the third year of life after the transfer of mosaic embryos compared with euploid embryos

R. Morales Sabater[1], B. Lledo[1], J.A. Ortiz[1], L. Arenas[1], A. Bernabeu[2], J.C. Castillo[2], R. Bernabeu[2]

[1]*Instituto Bernabeu, Genetics and Molecular Biology, Alicante, Spain*
[2]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Are perinatal and postnatal outcomes different following the transfer of blastocysts diagnosed as low-grade mosaic compared to euploid embryos?

Summary answer: Our study did not show any significant difference between children conceived after transferring low-grade mosaic versus euploid embryos regarding perinatal outcomes and physical health.

What is known already: A considerable percentage of embryos are classified as mosaic in IVF-cycles with preimplantation genetic testing for aneuploidy (PGTA). Although societies, such as Preimplantation Genetic Diagnosis International Society (PGDIS), have proposed recommendations for the transfer of these embryos, there is no worldwide consensus on the classification, especially in terms of the level of mosaicism, and their clinical management. There are studies on clinical outcomes in terms of implantation and pregnancy, and some of them have reported the birth of healthy children. However, studies evaluating perinatal outcomes and, physical health and development during childhood are limited.

Study design, size, duration: This retrospective cohort study includes 172 children born after the transfer of a single embryo analysed with PGT-A using next-generation sequencing (NGS), between October-2017 and August-2022. Children were divided into two groups, according to whether they were classified as euploid (n = 115) or mosaic embryo (n = 57) after PGT-A. All mosaic embryos carried a level of mosaicism below 50%. Data related to the level of mosaicism, number of chromosomes involved or type of alteration were reviewed.

Participants/materials, setting, methods: This study analyses clinical parameters/outcomes during gestation, birth and postnatal period, including prenatal test, pregnancy and delivery complications, type of delivery, breastfeeding, incubator/neonatology stay, congenital anomalies, maternal and gestational age, birth weight, height and head circumference, Apgar-score and health problems or chronic diseases until today. The oocyte/sperm age and their origin were also analysed. The differences between groups were evaluated by R (4.2.0). In children from mosaic embryos, postnatal karyotyping was offered to the parents.

Main results and the role of chance: According to mosaicism characteristics, 61.4% of embryos had 25-39% of mosaicism and 38.6% had 40-50%,

82.5% had one chromosome affected and 17.5% two chromosomes. No significant differences were observed between the euploid and mosaic groups in pregnancy and delivery complications, type of delivery and gestational age (39.22 ± 1.92 weeks in euploid group vs 39.00 ± 1.78 in mosaic), however maternal age was higher in mosaic group (40.07 ± 3.32y vs 38.27 ± 3.06y, $p < 0.001$). Regarding newborn parameters, no differences were reported in birth weight, height and head circumference in euploid group compared to mosaic group (3222 ± 581 vs 3227 ± 530g, 49.92 ± 2.67 vs 50.13 ± 2.65cm, 34.50 ± 1.87 vs 34.50 ± 1.86cm; $p > 0.05$), neither in the Apgar-score (8.58 ± 2.48 vs 8.96 ± 1.79, $p > 0.05$) nor in the incubator/neonatology stay. With regard to congenital anomalies, their incidence was similar in both groups (8.7%, euploid vs 7.0%, mosaic) and in all cases were minor anomalies. No health problems/chronic diseases were recorded in either group, with the average age of the child at present being 3.48 ± 0.81y in euploid group and 2.92 ± 1.32y in mosaic. Prenatal testing was higher in the mosaic group, being carried out in 49.1% of pregnancies (23 non-invasive test and 4 amniocentesis) with normal result. Moreover, postnatal karyotype was performed in 6 children from mosaic group with normal result.

Limitations, reasons for caution: This study was limited by the sample size. Further larger studies are needed to ensure that the health outcome of children conceived after low-grade mosaic embryo transfer is comparable with children conceived after euploid embryo transfer.

Wider implications of the findings: Data following the transfer of blastocysts diagnosed as mosaic remain limited, especially in terms of neonatal/early-childhood outcomes. Our study suggests that the transfer of low-grade mosaic embryos lead to healthy children and provides further perinatal and postnatal clinical data. The normal prenatal/postnatal karyotype in the analyzed cases provides further reassurance.

[9]KU Leuven, Department of Public Health and Primary Care, Leuven, Belgium

Study question: To investigate the validity of the association between the development of female specific malignancies, including ovarian, endometrial, breast and cervical cancer following fertility treatment.

Summary answer: There is a statistically significant increase in the incidence of ovarian cancer and borderline ovarian tumours associated with fertility treatment.

What is known already: Approximately 1.3 million IVF cycles have been performed since 1991. The association between fertility treatment (FT) and female-specific cancers however, remains contentious, largely due to the conflicting outcomes published in various meta-analyses.

Study design, size, duration: A thorough literature search of the Cochrane Database of Systematic Review, EMBASE, Google Scholar and Pubmed was carried out to identify relevant systematic reviews and meta-analyses, from inception up until April 2022.

Participants/materials, setting, methods: The inclusion criteria included original studies stating the incidence of cancer in FT and control groups (non-FT). The principal outcome of interest was the incidence of cancer (breast, endometrial, cervical, and ovarian) in FT and non-FT groups. The effect estimates, Hazard Ratios and Odds Ratios (OR) were extracted, or calculated de novo. The strength of evidence and extent of potential biases were summarised.

Main results and the role of chance: In total, 3129 publications were identified, and 11 meta-analytical reviews were included. This umbrella review synthesised 324 meta-analyses, including data from over 20 million patients. The incidence of ovarian cancer (OR 1·21;95% CI 1·00-1·45) and BOTs (OR 1.87;95%CI 1·18-2.97) was higher in the FT compared to non-FT group. The meta-analyses related to ovarian cancer was statistically significant ($p < 0.05$), using a random-effects model. There was no significant association demonstrated between FT and the incidence of cervical, breast or endometrial cancer.

Limitations, reasons for caution: Although it has been demonstrated that exposure to fertility treatment does significantly increase the risk of ovarian cancer and BOTs, further studies are required in order to draw accurate conclusions.

Wider implications of the findings: Understanding the potential long-term sequelae of FT is fundamental to guide counselling and enable individuals to make informed decisions about their reproductive future. Clinicians should engage in appropriate patient selection, with those deemed to be at a higher risk, selected for more personalised fertility treatment and careful preventative follow-up.

[4]IVIRMA London- Research Health Institute La Fe, Reproductive Medicine Research Group, Valencia, Spain

Study question: What is the impact of fertility preservation (FP) procedures and cancer treatment on relapse, survival, ovarian damage and pregnancy outcomes in oncological patients?

Summary answer: FP technique (including ovarian stimulation for oocyte vitrification) does not affect relapse or survival rates even in hormone dependant tumours.

What is known already: FP has become a crucial part of oncological evaluation of young women facing cancer given the high survival rates achieved. Oocyte vitrification (OV) and ovarian cortex cryopreservation (OCC) are the main techniques offered to these patients at the moment. However, information on the true incidence of premature ovarian insufficiency (POI), return rates to use the cryopreserved material and the natural pregnancy rates achieved in these patients is still limited. Moreover although there is some data about the safety of these techniques the impact of FP on disease survival is yet to be definitely assessed.

Study design, size, duration: Prospective cohort study. 695 patients enrolled since 2001 until 2016. Patients referred to FP unit in a public hospital setting (Hospital Peset Valencia 2001-2006 and University Hospital La Fe 2007-2016). After evaluation 556 patients received a FP technique (OV, OCC or embryo vitrification) and 139 patients did not receive any due to medical reasons or patient's choice. Minimum follow-up 5 years after enrolment

Participants/materials, setting, methods: Baseline characteristics including type of cancer and previous chemotherapy at diagnosis and prior to FP technique were recorded followed by risk of chemotherapy treatment received, relapse, survival, POI and poor ovarian reserve (POR) occurrence and pregnancy outcomes. Primary outcome was median survival time after FP in months. Secondary outcomes included relapse rate, POI and POR incidence, usage FP rate, clinical pregnancy and live birth (LB) rates naturally and after FP use.

Main results and the role of chance: There were no differences in survival comparing patients undergoing FP versus no FP (median 89.67 vs 92.81 months, $p = 0.3$). However, patients that used their cryopreserved material survived more than those who did not (97.3 vs 89.5, $p = 0.012$). When assessing survival rates comparing patients that had approval to get pregnant versus those who did not we found a higher survival in the former (98.84 vs 84.79 months, $p < 0.001$). Breast cancer patients with hormone dependent tumors undergoing ovarian stimulation for OV vs OCC had no differences in survival (95.62 vs 87.38 months, $p = 0.37$). POI incidence was 20.29% ($N = 141$). POI patients were significantly older (32.28 vs 29.63, $p < 0.001$) and had received high-risk chemotherapy more frequently (31.74% vs 2.27%, $p < 0.001$). Ovarian damage incidence (including also POR) was 48.06% ($N = 334$). Eighty-six patients (15.47%) used their cryopreserved material. Among the patients with pregnancy wish ($N = 266$) there were 84 spontaneous live births (31.58%). Patients that conceived naturally were significantly younger (30.71 vs 33.46, $p < 0.001$) and the chemotherapy received was more frequently low-risk (43.20% vs 23.52%, $p = 0.018$). There were 37 LB after use of FP (37/86, 43.02%). Patients with a higher ovarian reserve percentile had a higher chance of achieving a natural LBR (OR 1.016, 1.005-1.027, $p = 0.004$)

Limitations, reasons for caution: The higher survival found in patients using their cryopreserved material is mediated by the prognosis of the disease itself that limits the chance of pregnancy to those with a stable disease.

Wider implications of the findings: FP does not have a negative impact on survival even if ovarian stimulation is used. Almost half of the patients had ovarian damage (POI or POR) as a result of treatment; this is higher than previously reported. Among the patients with fertility wish around one third achieved a LB naturally.

Study question: What are the fertility outcomes of women who tried to conceive after breast cancer treatment and FP?

Summary answer: Three to-ten years after FP for breast cancer, less than half of patients tried to conceive but 39% of them had a child, mainly spontaneously.

What is known already: Breast cancer is the most common cancer in women of childbearing age. Because of the gonadal toxicity of treatments and temporary contraindication to pregnancy, fertility after cancer treatment is often impaired. Different FP techniques can be offered. Although it is well established that pregnancy in breast cancer survivors is safe, little is known on the incidence of pregnancies after breast cancer treatments in women having undergone FP, the way those patients conceived and outcomes.

Study design, size, duration: This is a retrospective observational, bicentric cohort study. All patients having undergone FP before breast cancer treatment (oocyte and/or embryo vitrification after controlled ovarian stimulation (COS) or *in vitro* maturation and/or ovarian tissue cryopreservation) between January 1, 2013 and July 31, 2019 were included (n = 844). Patients for whom data on post-cancer pregnancy attempt was missing (n = 195) were excluded from the analysis of pregnancies.The cut-off date was March 1, 2022.

Participants/materials, setting, methods: For women who got pregnant, the time to conception was calculated between the 1st FP consultation (CS1) and the day of the estimated conception. For those who did not conceived, we considered the time between the CS1 and the cut-off date or the date of patient's death. Cumulative incidences of pregnancy and live birth were calculated. A logistic regression Cox model was performed to study the predictive factors of pregnancy and live birth.

Main results and the role of chance: Among the 649 patients with available data on post-cancer pregnancy attempt, 255 (39.3%) tried to conceive. Overall, 135 (52.9%) of them achieved a pregnancy, mainly spontaneously (79.3%), and 99 (38.8%) reported a live birth. At the CS1, 76.3% of women were in couple and 42.3% already had at least a child. The mean age at CS1 was 32 ± 4.2 years. Invasive ductal carcinoma was the diagnosis in 95.8% of women and 45.7% had COS for FP. In our cohort, 48 months after CS1, the cumulative incidence of pregnancy was 33.1% (CI95% [27.6-37.9]). After adjustment on age, parity, type of chemotherapy and hormonotherapy, only multiparity at diagnosis and absence of chemotherapy were found to be positive predictive factors of pregnancy after cancer. Only multiparity was found to be negatively associated with live birth (RR0.47 [0.33-0.67]). Of the 793 patients who vitrified oocytes/embryos, 68 reused them (26.6% of the patients who tried to conceive) and obtained 8 live births. Women using their cryopreserved biological material were older at CS1, had lower ovarian reserve parameters and had vitrified embryos. Ovarian reserve parameters and number of cryopreserved oocytes were higher while age at CS1 was lower in patients reporting a live birth after oocyte/embryo thawing.

Limitations, reasons for caution: Due to the retrospective nature of the study, some data is missing. Even if the median follow-up is more than 4 years, a longer follow-up is necessary

Wider implications of the findings: Although pregnancy rates after breast cancer are reduced, most of conceptions are achieved spontaneously. Our findings provide useful information to advise women on the different techniques of FP, their efficacy and safety.

O-085 Patients support through a mobile application improves ART outcomes across all age groups

H. Raanani[1], R. Israel[2], D. Averbach[2]

[1]*Tel Hashomer, OBGYN, Ramat Gan, Israel*
[2]*not applicable, not applicable, Tel Aviv, Israel*

Study question: Assess the effectiveness of fertility treatment companion mobile application, which provides tracking, adherence tools, education and community support, in improving ART outcomes

Summary answer: Results showed that patients use of mobile application during treatment had significantly improved ART outcomes compared to the CDC average, across all age groups

What is known already: Growing numbers of adults use digital health tools to diagnose and manage their health conditions. Direct-to-consumer, interactive, diagnostic apps with information and personalization capabilities beyond those of static search engines are rapidly growing in use (M. Millenson et al. 2018).

A very limited amount of research has been conducted on mobile application's ability to impact ART outcomes (I. Robertson, etc. 2021). Existing studies include small control groups and limited data.

To date, though sparse, most research has focused on mobile applications' and internet-based technologies' ability to mitigate the psychological effects of infertility (Meyers & Domar, 2021).Study design, size, duration:

Retrospective analysis conducted using Embie mobile application's database (EMU) between Jan 1, 2021 and Dec 31, 2022. Study group included 6449 cycles by 5067 users self-reported in real-time.

EMU stimulation cycle cancelation rates and pregnancy outcomes, at week 20 of pregnancy, were compared to CDC 2020 preliminary report of LBR and stimulation cycle cancellation rates, divided into 4 age groups; <35, 35-37, 38-40 and >40.

EMU population included 53% U.S., 47% out of U.S.

Participants/materials, setting, methods: Participants are fertility clinic patients globally who voluntarily downloaded the mobile application via the App or Play stores.

The application provides ART cycle protocol tracking and monitoring, eggs retrieved, embryo, transfer and pregnancy results, etc, along with educational articles and community support.

Self-reported data is entered in real-time by the user. We cleared, merged and analyzed using python, then compared the CDC report by age group. Chi square significance performed comparing two proportions (with continuity correction).

Main results and the role of chance: 4426 EMU of stimulation cycles analyzed 2319, 903, 683, 521 by age respectively.

EMU stimulation cancelation rates 2.76%, 3.54%, 6.00%, 7.49% respectively.

2073 EMU transfer cycles analyzed 1078, 431, 336, 228 by age respectively.

Ongoing EMU pregnancy at 20 weeks was observed in 618, 252, 170, 75 respectively.

Ongoing EMU pregnancy rates at 20 weeks 57.33%, 58.47%, 50.60%, 32.89% respectively.

Delta CDC/EMU stimulation cycle cancellation rate 5% vs 2.76%, 7.20 vs 3.54%, 10.10% vs 6.00%, 14.20% vs 7.49% respectively.

Delta CDC LBR per transfer data vs EMU ongoing pregnancy 49.80% vs 57.33%, 45.50% vs 58.47%, 40.40%vs 50.60%, 23.90% vs 32.89% respectively.

Delta CDC LBR per transfer data to EMU U.S. users' only ongoing pregnancy 49.80% vs 62.86%, 45.50% vs 65.77%, 40.40% vs 58.17%, 23.90% vs 43.62% respectively.

Statistically significant analysis by chi square score showed all delta measurements to be significant ($p < 0.0001$).

Limitations, reasons for caution: Self-reported data may not be as reliable as data collected in a clinical setting. However, the use of a large cohort reduces the impact of a single error. Additionally, LBR were compared to ongoing pregnancy at 20 weeks, which can influence the outcomes at a low rate.

Wider implications of the findings: Our results suggest that fertility treatment mobile applications can significantly improve ART outcomes and patient's experience. Clinics should consider adopting such tools as an adjunct to care.

The ability to collect and analyze big data globally in real-time will impact future ART research, medical understanding and improvement of patient's fertility treatment.

O-086 Co-development of Orchid mobile application for supporting fertility intentions and reproductive choices

C. Stewart[1], B. Grace[1], J. Hall[1]

[1]*University College London, Sexual and Reproductive Health, London, United Kingdom*

Study question: What does co-development bring to the design of a mobile application (app) for supporting fertility intentions and reproductive choices?

Summary answer: Co-development of the app for supporting fertility intentions and reproductive choices informed the design and content, from expressed preferences, ensuring acceptability by the end user.

What is known already: We sought to develop a digital tool to support people of reproductive age to understand their pregnancy preferences and fertility intentions; helping them to prepare for pregnancy, improving pregnancy outcomes, preventing unplanned pregnancies and reducing inequalities in maternal health. Orchid encourages the person to consider that they have a choice about their fertility intentions and to reflect on their personal reproductive goals and how this may fit with other life goals. We aimed to co-develop a mobile app via a person-centred approach, which draws on behaviour change theory.

Study design, size, duration: The app development was conducted via University College London. Co-development was conducted online over five rounds (four online surveys and one online group discussion) from November 2022 – February 2023. Round 1 – Content mapping, Round 2 – App layout, Round 3 – Online group discussion of content and layout, Round 4 – App design, and Round 5 - Functioning pilot app.

Participants/materials, setting, methods: Participants were invited via a database of potential research participants and were purposefully selected to ensure diversity and inclusion. The co-development group was made up of 10 women from across the UK; aged 19-44 years with a range of relationship status' (married, divorced, cohabiting and single), ethnicities (White n = 8, Asian n = 1, Mixed n = 1) and family sizes.

Main results and the role of chance: We gained feedback from our co-development group through online surveys, made up of a combination of structured and open text questions. We also held an online group session which allowed us to have an in-depth discussion about the content and look of the app. As a result of the co-development feedback, we redesigned key elements of the app; altering the language used throughout, including the wording of the pregnancy prediction, adding extra information about the reproductive preference groups and including a wider range of resources. The overall look of the app also changed considerably, with feedback from the co-development group helping to make decisions regarding the colour scheme, the number of screens, the layout and presentation of information. Final user testing was also conducted by the co-development group to verify functionality of the app.

We performed multiple iterations of co-development – with a survey at every development stage – and used the feedback to inform our decisions throughout the development process to ensure acceptability to the end user.

Limitations, reasons for caution: There was a limited number of participants involved in this, the first stage of developing a Minimum Viable Product (MVP) of the app. A larger group of even more diverse individuals will be needed for the next stage, which will likely increase the complexity of the co-development process.

Wider implications of the findings: We co-developed an MVP app with a sample population, representative of our end-user. Participants were involved in every stage of the development process and provided a positive evaluation of the product. People must be viewed less as consumers and more as contributing partners in their care.

[12]Univfy Inc., Provider Solution, Los Altos, U.S.A.

Study question: Does the use of patient-centric, ML-prognostics counselling report (Univfy® PreIVF Report) affect assisted reproductive technology (ART) conversion (first ART cycle usage) and LB rate (LBR)?

Summary answer: The use of patient-centric, ML-prognostics counselling report (Univfy® PreIVF Report) by fertility specialists is associated with higher ART conversion and LBR among new patients.

What is known already: ART is a highly effective and safe treatment for clinical infertility. However, ART remains vastly underutilised resulting in missed opportunities to help more people build families. Commonly used age-based trends often do not address patients' perceived risks including their own ART success probability and ART cost burden as related to their personalised LB probabilities. We previously reported the use of artificial intelligence (AI)/ML to generate patient-centric counselling reports based on ART success prediction models developed and validated for each fertility centre to address their local patient populations in ways that are personalised, relevant and actionable.

Study design, size, duration: Retrospective cohort analysis. Eight fertility centres from 22 locations across 9 states (US) and Ontario, Canada contributed to the research design, compilation of outcomes data, and interpretation of results. Five centres provided ART utilisation and outcomes data for 15,289 new patients seen in each centre's study period when the Univfy® PreIVF Report was available and data were submitted for aggregated research analysis. Each centre provided 4-6 years of data within the period 2016-2022.

Participants/materials, setting, methods: The effect of Univfy or No-Univfy Group on ART conversion was analyzed by Chi square tests using aggregated data and separately for each centre's data, for 3 timed analyses, 180-Day, 360-Day and "Ever" (no restriction) after new patient visit. Patients who received the Univfy® PreIVF Report prior to IUI or ART conversion, or had no such conversion after receiving it were placed into the Univfy Group. The No-Univfy Group comprises patients who did not receive a report.

Main results and the role of chance: Univfy report usage was associated with higher conversions to Direct-ART (by 2.6-, 2.4-, 1.9-folds) and Any-ART (by 2.9-, 3.0-, 2.4-folds) in the aggregated data when analyzed for 180-Day, 360-Day and Ever, respectively; p-value < 0.001. Direct-ART is ART conversion without prior IUI(s); Any-ART conversion includes ART conversion with or without prior IUI(s).

In the centre-specific analyses, the fold increase in Direct-ART and Any-ART conversions ranged from 1.8 to 4.5 and 2.2 to 4.7, respectively, in the 360-Day period; p-value <0.001. Univfy® PreIVF Report usage was associated with an increase in estimated LBR ranging from 2.1 to 1.3 folds for the Univfy Group compared to No-Univfy Group (360-Day analysis, $p < 0.001$) based on conservative versus liberal scenarios. Similar ART conversion and LBR results were observed for 180-Day and Ever analyses, $p < 0.001$.

We used conservative to liberal assumptions for IUI-LBR and NC-LBR because IUI and NC outcomes were not readily available. (Conservative: IUI-LBR 15%, natural conception (NC)-LBR 5%; Liberal: IUI-LBR 25%, NC-LBR 20%). Estimated LBR for ART used clinical ongoing pregnancies and documented live births as LBs and the following LBR assumptions: freeze-all with no transfers yet (50%); gestational carrier ART (45%); ART with unknown outcomes (0%).

Limitations, reasons for caution: This study was not prospective or randomised. The intended report usage was to support physicians when counselling patients. Although we observed comparable report and ART usage across predicted ART-LB probabilities, there is potential unintentional bias towards higher report or ART utilisation among patients with more favorable clinical characteristics.

Wider implications of the findings: These results represent our retrospective experience in diverse geographies in North America. We endeavor to collaborate with additional centres to test the reproducibility of AI/ML-driven, validated personalized IVF prognostics on improved overall live birth outcomes and ART access when counselling patients about treatment options.

O-088 Social Networks (SNs) in reproductive medicine: the experience of the 5 Young ESHRE Ambassadors 2022 (5YEA)

A. Anastasi[1], R. Einenkel[2], I. Gazzo[3], P. Makwana[4], T. Penna[5]

[1]Delta Hospital - AUSL pf Ferrara, Physiopathology of Human Reproduction and IVF, Ferrara, Italy
[2]University Hospital Bonn, Gynecologic Endocrinology and Reproductive Medicine, Bonn, Germany
[3]University of Genoa, department of Neurosciences- Rehabilitation- Ophthalmology-Genetics- Maternal and Child Health, Genoa, Italy
[4]Vasundhara Hospital Ltd, ART department, Jodhpur, India
[5]University of Turin, Department of Law, Turin, Italy

Study question: The 5YEA, experienced how SN can promote dissemination of evidence based scientific education and counter misinformation for both scientific community and general public.

Summary answer: An incorrect use of SNs can lead to the massive dissemination of incorrect information but if used correctly they can help scientists, patients and general-public.

What is known already: SNs have proved to be a very powerful weapon. SNs are applications available on the Internet, a global computer network that uses the Web as a service to navigate through documents. Their rise, in conjunction with the development of mobile phones, has affected all professional sectors, including the scientific community.

Social networks have multiple uses from facilitating scientists to communicate and make their research more accessible, to healthcare professionals generating interest and helping the general public be more aware about their health & wellbeing, all this while countering the the uncontrolled dissemination of misinformation.

Study design, size, duration: From ESHRE annual meeting 2022, the 5YEA shared scientific messages and personal considerations on research and topics presented at the meeting. Through the various SNs(mainly Twitter-Instagram-Facebook-LinkedIn) they have directed many participants to follow the topics from the comfort of their homes and, generating curiosity for people even outside the scientific community. Even today, the topics shared on SNs are followed by users both from the scientific world and from the whole social world.

Participants/materials, setting, methods: The 5YEA actively participated during the 5 days of the annual meeting. The sharing of their messages on the SN involved thousands of registered users across various platforms. The conspicuous increase in the number of users who have begun to follow them has allowed us to express the considerations of this abstract.

Main results and the role of chance: Scientific integrity, defined in particular by the methodological rigor and honesty of the researcher, is essential for the validation of his work by the scientific community. SNs, accessible to research professionals, on the one hand, and to the general public, on the other, have given specialists a voice to raise awareness of scientific integrity in these two populations. SNs are also a forum for discussing methodological weaknesses or distorted results of some studies. But they are also an educational tool to educate their readers about scientific fraud.

SNs has increased the massive diffusion of fake news. Raising scientists' awareness of the use of these powerful communication tools seems to be a necessity, as these tools can interfere with the visibility of their research work but also, sometimes even, with their private life.

Today on SNs there is therefore a struggle going on, difficult to ignore, which questions the credibility of scientific discourse and its integrity and for which very few researchers are prepared. It is a fight for which it is necessary to attract the attention of all generations of scientists. This fight must not be lost to restore and preserve the still fragile trust between science and society.

Limitations, reasons for caution: New SN platforms are born every day. Some are reserved to scientific professionals (high scientific rigor), others not (general public creates confusion by indulging in inappropriate comments). Given limitations to text length, information is always condensed, while users are pushed to share information frequently to get a greater reach.

Wider implications of the findings: With all the emerging and sometimes misinformed discussions taking place on social media, experts should spend more time clarifying them. However, the quantification and corresponding appreciation of this work is currently lacking.

Trial registration number: not applicable

O-089 Using ChatGPT to answer patient questions about fertility: the quality of information generated by a deep learning language model

K. Beilby[1], K. Hammarberg[2]

[1]*Monash University, Obstetrics & Gynaecology, Melbourne, Australia*
[2]*Monash University, Global and Women's Health- Public Health and Preventive Medicine, Melbourne, Australia*

Study question: What is the quality of information provided by ChatGPT when using common patient questions as prompts?

Summary answer: Overall, the quality of the information generated by ChatGPT was high with little evidence of commercial bias.

What is known already: People seeking fertility-related information rely on internet sources when deciding on reproductive planning and assisted conception. The quality of information within the commercial landscape of infertility treatment is poor. ChatGPT, a variant of Generative Pre-trained Transformer v3 (GPT-3), is a language model that uses deep learning to generate human-like text. Given prompts, it generates answers by predicting the next word in the sequence based on patterns learned from training data. The training data for GPT-3 is not curated, but a snapshot of the Web, which includes all kinds of information, including biases that may exist within sources.

Study design, size, duration: Ten common patient questions were used as prompts. Three questions related to fertility awareness (impact of female/male age on fertility and fertile window in the menstrual cycle), one to the chance of success with IVF, one to elective egg freezing, one to the benefits of add-ons, one to PCOS and pregnancy, one to choosing a fertility clinic, and one to how many IVF cycles should be attempted.

Participants/materials, setting, methods: Two experts independently scored the quality of the information generated by the ChatGPT using a scoring matrix with a range of 0 to 7 where higher scores indicate higher quality. Text was rated against humanistic answers based on how well it corresponded (0-3), evidence of commercial bias or controversial claims (no = 1, yes=0), use of accurate proportions/ statistics and whether it was stated that medical advice should be sought (yes=1, no = 0).

Main results and the role of chance: The scores returned by the two experts were closely aligned with only one point difference for one of the answers. This discrepancy was resolved through discussion. While none of the answers received the maximum score of 7, 6/10 scored 5 or more and 3 received a score of 3-4. Only one answer, the answer to the question about the benefits of add-ons, scored less than 3. This was also the only question where the response had evidence of commercial bias and one of only two that made claims that could be considered controversial.

Limitations, reasons for caution: The scoring method used in this study has not been validated and is exploratory in nature as this area of evaluation is emerging. However, the use of expert evaluation is common when assessing the performance of machine learning models and often used to fine-tune their parameters and improve their performance.

Wider implications of the findings: It is known that people seeking fertility-related information rely heavily on online sources such as clinic websites, consumer advocacy organisations, patient support groups and social media. Our findings suggests that ChatGPT may be a useful tool for patients seeking factual and unbiased information regarding fertility and fertility treatment.

P-468 Personalized embryo transfer guided by transcriptomic endometrial receptivity analysis (ERA) in infertile patients: a systematic review and meta-analysis

D. Glujovsky[1], K. Lattes[2], M. Miguens[1], R. Pesce[3], A. Ciapponi[4]

[1]*Cegyr - Eugin group, Reproductive Medicine, Buenos Aires, Argentina*
[2]*Centro de Infertilidad y Reproducción Humana CIRH. - Eugin group, Reproductive Medicine Dept, Barcelona, Spain*
[3]*Hospital Italiano de Buenos Aires, Reproductive Medicine Dept, Buenos Aires, Argentina*
[4]*Institute for Clinical Effectiveness and Health Policy IECS- Center for Research in Epidemiology and Public Health- National Scientific and Technical Research Council CONICET, Argentine Cochrane Centre, Buenos Aires, Argentina*

Study question: What is the effectiveness of a personalized embryo transfer (pET) guided by an endometrial receptivity test in assisted reproduction?

Summary answer: We have not found evidence supporting the routine use of a personalized embryo transfer guided by an endometrial receptivity test in any case yet.

What is known already: Currently, the outcomes of good quality embryo transfers are far from ideal. Clinical focus is shifting towards other actors that could play a key role in the good-quality embryos implantation failure, such as the endometrial preparation and the achievement of an embryo-endometrium synchrony, so that the embryo has a better chance to implant during the window of implantation (WOI). Today, there is a wide range of different endometrial receptivity tests that use different sets of genes to identify patients with displacements of their WOI in order to adjust the individual length of progesterone exposure in a personalized embryo transfer (pET).

Study design, size, duration: This is systematic review and meta-analysis were conducted following the Cochrane methods and the GRADE approach to rate the certainty of evidence (CoE). The protocol has been sent for registration to PROSPERO (CRD42022299827). We included studies that compared women that were tested with transcriptomic endometrial receptivity tests versus those that were not tested. We only included comparative studies, including randomized controlled trials (RCTs), and retrospective and prospective cohorts.

Participants/materials, setting, methods: Participants were women undergoing an infertility treatment (both with own or donor gametes), with or without repeated implantation failure (RIF), with or without preimplantation genetic testing for aneuploidies (PGT-A). Each of the above-mentioned populations was analyzed separately as different subgroups. Electronic searches in CENTRAL via the Cochrane Register of Studies Online (CRSO), PubMed, and Embase were performed from inception to October 2022. Screening, study inclusion and data extraction was performed by pairs of independent reviewers.

Main results and the role of chance: We included 35 studies. Two of them were RCTs and 25 were cohort studies that compared pET guided by an endometrial receptivity tests guided versus sET in women with non-tested endometrium. Besides, we included 16 studies that compared women with sET with a receptive endometrium versus pET in women with non-receptive endometrium. And we included three studies that compared pET guided by an endometrial receptivity test in a specific population of women (RIF or adenomyosis) versus a control population. The two RCTs included women with no history of RIF. In non-RIF women, no important differences (moderate-CoE) were found in live birth rate (LBR) and clinical pregnancy rate (CPR). In that population, cumulative CPR may be higher with pET (RR 1.15, 95%CI 1.00-1.34; low-CoE) but no differences were found in cumulative LBR. Seven cohort studies that adjusted by confounding were meta-analyzed. In RIF, pET may improve the CPR (OR 2.50, 95% CI 1.42-4.40; low-CoE) but, in agreement with the RCTs, no benefits were found in non-RIF. In summary, routine use of pET guided by endometrial receptivity tests is not supported by current published evidence in non-RIF women. However, low-CoE suggests that it may be useful in RIF.

Limitations, reasons for caution: Most data come from non-RCTs which increases the risk of bias. Besides, the large heterogeneity found in the population, interventions and comparisons led to large imprecision due to the few studies per analyzed strata. It is important to avoid the extrapolation of the results to any different setting.

Wider implications of the findings: Routine use of pET guided by endometrial receptivity tests is not supported by current published evidence in non-RIF women. However, low-CoE suggests that it may be useful in RIF. Better designed studies are needed to find out if any of these tests work in any specific population.

Trial registration number: not applicable

Abstract citation ID: dead093.105

P-480 An endometrial receptivity scoring system evaluated by ultrasonography in patients undergoing frozen-thawed embryo transfer: a prospective cohort study

O. Yan[1], P. Ynagqin[2], M. Yuyao[3], X. Li[4]

[1]*Reproductive and Genetic Hospital of CITIC-Xiangya, Imaging departement, Changsha, China*
[2]*Reproductive and Genetic Hospital of CITIC-Xiangya, Scientific research department, Changsha, China*
[3]*Reproductive and Genetic Hospital of CITIC-Xiangya, Imaging Departemnet, Changsha, China*
[4]*Reproductive & Genetic Hospital CITIC-Xiangya, Imaging Department, Changsha, China*

Study question: Can a scoring system based on ultrasound indicators evaluate the endometrial receptivity (ER) in a noninvasive and effective manner?

Summary answer: A noninvasive ultrasound scoring system was proposed, through which, a patient's ER situation can be assessed in a noninvasive, efficient and accurate manner.

What is known already: Endometrial receptivity (ER) refers to the receptiveness of the endometrium to embryonic implantation and subsequent development. The endometrium plays a crucial role in embryo implantation, especially when the embryo quality is good. Ultrasound technology has become a routine method for ER evaluation. The independent evaluation value of various ultrasonic indicators is controversial. Some researchers designed a multi-index prediction system, but the prediction results vary. To further understand ER, we performed this prospective cohort study to help evaluate ER in a noninvasive and efficient manner.

Study design, size, duration: This prospective study included 197 infertile women undergoing FET from April 2019 to July 2021. Transvaginal three-dimensional ultrasound was performed on the transfer day to evaluate ER, including endometrial thickness, morphology, volume, movement, blood flow and flow index.

Participants/materials, setting, methods: This study was conducted at the Reproductive and Genetic Hospital of CITIC-Xiangya. The primary outcome of this study was the clinical pregnancy rate. All included patients were divided into a pregnant group and a nonpregnant group according to whether clinical pregnancy was achieved.

Main results and the role of chance: A total of 197 FET patients with 139 pregnancies (70.5%) were analysed. Primary infertility (adjusted odds ratio (aOR), 1.98; 95% confidence interval (CI), 1.01–3.882; $P = 0.047$) and more frequent endometrial peristalsis (aOR, 1.33; 95% CI, 1.028–1.722; $P = 0.03$) were protective factors against clinical pregnancy. Scores of 1 to 2 were given according to the relationship between different groups of ultrasonic indices and the clinical pregnancy rate (CPR). A patient's ER score was the sum of the scores of the 6 items. The ER score was significantly higher in the pregnant group than that in the nonpregnant group (7.40 ± 1.73 versus 6.33 ± 1.99, $P = 0.001$). The CPR increased as the ER score increased; the CPR significantly improved for the group with total ER scores of < 6 to ≥ 6 (45.5% versus 75.6%, $P = 0.001$).

Limitations, reasons for caution: First, this study only included natural cycles of FET. The application for other populations remains to be verified. Second, perhaps with the progress of ultrasonic technology, there will be new and more direct indicators. Third, we did not further explore the relationship between ER and the live birth rate.

Wider implications of the findings: The scoring system provides a broader idea for guiding clinical practice to perform more efficient transplantation and provide a noninvasive evaluation of ER in the future.

Trial registration number: None

Abstract citation ID: dead093.106

P-534 Serum progesterone levels on the day of embryo transfer do not affect pregnancy outcomes after euploid blastocyst transfer: data from artificial cycles with intramuscular progesterone

W. Chen[1], Y. Xu[1], Y. Xu[1], F. Gu[1]

[1]*The First Affiliated Hospital- Sun Yat-sen University- Guangzhou- Guangdong-China, Reproductive Medicine Center, Guangzhou- Guangdong, China*

Study question: Do serum progesterone levels on the day of embryo transfer (ET) have an impact on implantation and pregnancy outcomes?

Summary answer: Serum luteal progesterone levels were not associated with pregnancy outcomes under the condition of utilizing 60mg intramuscular progesterone for luteal support in artificial cycles.

What is known already: It was recognized that circulating progesterone level might be associated with frozen-thawed embryo transfer (FET) success, and a serum progesterone level above a certain threshold at the time of blastocyst transfer improved live birth rates (LBR) and reduced risk of miscarriage in artificial FET cycles. However, this hypothesis is controversial as the previous findings were based on data using vaginal progesterone as luteal phase support with various doses and timing of administration. Studies evaluating euploid-only FET cycles with intramuscular progesterone were lacking.

Study design, size, duration: The study incorporated infertile couples undergoing (preimplantation genetic testing, PGT) from 1st January 2018 to 31st July 2021. It is a retrospective cohort study including 771 patients who underwent single frozen-thawed euploid blastocyst transfer after an artificial endometrial preparation cycle with 60mg intramuscular progesterone daily for luteal support. Each patient only contributed one cycle per cohort.

Participants/materials, setting, methods: Patients with recurrent implantation failure, endometrium 7.0 mm and cycles with gonadotrophin releasing hormone analogue down regulation were excluded. Serum progesterone measurements were taken on the day of ET, approximately 20 ± 2 hours after the last injection of progesterone. The primary outcome was LBR based on serum progesterone levels. Secondary outcomes were the relationship between serum progesterone levels and clinical pregnancy rate, miscarriage rate as well as obstetrical and neonatal outcomes.

Main results and the role of chance: The median of serum progesterone levels was 11.80 ng/ml [9.95, 14.60] (median/IQR) and the overall LBR, clinical pregnancy rate and miscarriage rate were 55.6%, 64.33% and 10.69% respectively. Patients with the lowest centile of serum progesterone level (≤P10, ≤8.2ng/ml) had a similar clinical pregnancy rate (62.0% vs 64.6%), live birth rate (50.6% vs 56.2%) and miscarriage rate (12.2% vs 10.5%) compared with the rest of patients. After dividing patients in deciles according to serum progesterone levels, no differences in LBR were observed among groups and no correlations were found between progesterone levels and the other pregnancy outcomes. Multivariate regression analysis confirmed that serum progesterone levels did not affect the LBR after adjusting for possible confounders (age, body mass index, PGT indication, primary infertility, history of miscarriage, endometrium thickness, day of blastocyst and embryo quality) with adjusted (OR) 0.99, 95%CI 0.96-1.03), while the day of blastocyst (D6 vs. D5: aOR 0.47, 95%CI 0.33-0.65) as well embryo quality (good quality embryo vs. available embryo: aOR 1.88, 95%CI 1.38-2.58) were associated with LBR independently. Similarly, serum progesterone in their lowest levels did not negatively impact other pregnancy outcomes (ex. clinical pregnancy rates, miscarriage rates) and the perinatal outcomes.

Limitations, reasons for caution: This is a retrospective cohort study and the results only apply for patients under artificial cycles with intramuscular progesterone. Moreover, the time interval between the last administration of progesterone and the blood test was not controlled in the present study.

Wider implications of the findings: Serum progesterone level may not influence the FET outcomes independently in an artificial cycle with intramuscular progesterone. A daily dose of 60mg progesterone intramuscularly for luteal support is sufficient and the measurement of serum progesterone does not need to be performed in advance for most of the patients.

[6]IVI Foundation- IIS La Fe-, Human Reproduction, Valencia, Spain

Study question: Is endometrial scratching a useful add-on to be applied in assisted reproduction patients without recurrent implantation failure (RIF)?

Summary answer: Endometrial scratching results in significantly higher clinical and ongoing pregnancy rates per intention to treat (ITT) among women undergoing oocyte donation without RIF.

What is known already: The effect of endometrial injury or endometrial scratch (ES) on reproductive outcomes has been widely studied by randomized controlled trials but from the information obtained regarding its benefit on improving endometrial receptivity remains controversial. Oocyte donation programs (OD) provides with the ideal setting for this research, as the recipient's endometrial priming guarantees the homogeneity of the endometrium avoiding a deleterious differential effect of the stimulation on endometrial receptivity and makes comparable the quality of the oocytes and transferred embryos, then limiting the confounding factors involved in studies with autologous oocytes and their frozen surplus embryos, better addressing the research question.

Study design, size, duration: A multicentric, open-label, randomized controlled trial has been conducted in a private setting from Oct 2013-Nov 2022. Eligible recipients were randomly assigned in a 1:1 ratio to either ES (by pipelle biopsy in the luteal phase of the menstrual cycle prior to the embryo transfer, n = 303) or no intervention (NES, n = 310), through a computer-generated randomization list, and embryo transfers (ET) performed in the cycle following the intervention.

Participants/materials, setting, methods: 18-44 years aged ovum recipients with preserved ovarian function, 19-29.9 kg/m2, first/ second OD fresh embryo transfer, endometrial thickness > 6 mms, and 1-2 optimal quality blastocysts transferred. Exclusion: any adverse condition, RIF with OD, ET not performed in the cycle following the intervention. Outcomes included ongoing implantation rate (ongoing sacs/ embryo transferred), biochemical, clinical and ongoing pregnancy rates analyzed per ITT basis and per protocol strictly completed (PP, treatment correctly received, embryo transfer achieved).

Main results and the role of chance: A total number of 458 recipients underwent OD-embryo transfer, 226 in scratching arm and 232 in the NES group.

No differences existed in mean age and BMI of recipients and oocyte donors, oocytes retrieved and microinjected, fertilization rates, blastocysts transferred, endometrial thickness and estradiol /progesterone levels after their endometrial priming, nor other clinically relevant parameters.

The biochemical pregnancy rate was 62.6%95%CI(56.6-68.3) and 55.6%95%CI(49.7-61.3) in the ES arm and in NES arm on the ITT analysis (OR 1.073 95%CI(0.990-1.163), p = 0.088); and 75.3%95%CI(69.0-80.7) vs. 70.7%95%CI(64.3-76.4), respectively PP (OR1.048 95%CI(0.965-1.137), p = 0.266.

The clinical pregnancy rate was 57.1%95%CI(51.0-63.1) and 47.5% 95%CI(41.7-53.3) in the ES arm and in NES arm on the ITT analysis (OR = 1.102 95%CI(1.015-1.196); p = 0.021), and in the per protocol analysis, 68.6% 95%CI(62.0-74.6) vs 60.3%95%CI(53.7-66.6) respectively, OR = 1.086 95%CI(0.995-1.186), p = 0.066.

The ongoing pregnancy rate was 45.1%95%CI(39.1-51.2) and 36.3% 95%CI(30.8-42.1) in the ES arm and in NES arm on the ITT analysis (OR = 1.092 95%CI(1.007-1.183); p = 0.033), and in the per protocol analysis, 53.8%95%CI(47.0-60.5) vs 46.1%95%CI(39.6-52.8) respectively, OR = 1.080 95%CI(0.985-1.184), p = 0.101.

The ongoing implantation rate was in the PP analysis, 61.4%95%CI(55.1-67.8) in ES, and 56.5%95%CI(50.1-68.2) in NES respectively, p = 0.276, while in the ITT analysis, 51.3% 95%CI(45.4-57.2) vs 44.4% 95%CI(38.7-50.1), p = 0.098 in the ES arm and in NES arm.

Limitations, reasons for caution: The number of patients not fulfilling the complete procedure probably avoided to find significant differences on the PP analysis, and during the study, there may be some clinical and/or laboratory

changes through the years, that should have been affecting outcomes on both groups.

Wider implications of the findings: This RCT shows that ES in the luteal phase of the cycle preceding the OD embryo transfer in recipients without RIF would pose a significant benefit thus its consideration for all IVF patients can be advised at this point.

[3]*Medical University of Warsaw, Department of Gynecological Endocrinology, Warszawa, Poland*

Study question: Is it possible to predict clinical pregnancy using Machine Learning models on day 6 after embryo transfer to an acceptable degree of certainty?

Summary answer: Using selected biochemical markers it is possible to build a machine learning model to predict clinical pregnancy.

What is known already: Human chorionic gonadotropin (β-hCG) is considered the main early predictor of pregnancy. Due to the fact that the highest percentage of spontaneous abortions occurs in the first trimester predicting clinical pregnancy outcomes at the early stages of pregnancy is particularly difficult. The level of B-hcg measured at the early stages of implantation and the dynamics of its increase can help predict clinical pregnancy and predict its further development. However, the specific cut-off points at which pregnancy can be determined vary from study to study, and a different factor is often suggested to increase the certainty of β-hCG-based predictions.

Study design, size, duration: 1474 single frozen embryo transfers (1205 patients between 23 and 47 years of age), January 2019 -December 2022 were used for data modelling and statistical testing. The dataset consisted of endocrinal markers:β-hCG, PRG (progesterone), E (estradiol) measured on the 6th day after ET and other practitioner-chosen data: age, PGD results, embryo quality status, RIF or RPL history, embryo maturation days as well as pregnancy outcomes. Exclusion criteria were: PRG > 50ng/ml, β-hCG >70 mIU/ml.

Participants/materials, setting, methods: A machine learning model for predicting clinical pregnancy was trained using the gradient boosting technique. The model used 100 decision trees with 8 leaves, maximal depth of 2 nodes and a learning rate of 0.1. The performance of the model was measured using the accuracy score metric and area under ROC (AUC). Feature importance was based on Shapley values. Additional analysis was performed using statistical testing using a two-sided Student's t-test.

Main results and the role of chance: A Machine Learning naive model employed chosen variables to predict clinical pregnancy. The most important variables turned out to be the serum level of β-hCG and PRG on day 6 after embryo-transfer. The final model, limited to those variables, performs with an accuracy of around 83 % (accuracy score = 0.834), the area under ROC (AUC) was 0.927. Based on Shapley values, β-hCG followed by PRG are the most relevant for the model's predictions. Low PRG concentrations increased the chances of clinical pregnancy. The findings were confirmed by additional statistical analysis. Observations were divided into two groups for which the cut-off point was the level of PRG of 24 ng/ml – the median for the whole group. The probability of clinical pregnancy is higher in the group where the serum PRG is below 24 ng/ml even if β-hCG levels are the same. A statistically significant difference between these groups regarding β-hCG (P value < 0.001) was noticed. In order for serum β-hCG to be used as a more accurate clinical pregnancy predictor its level should be interpreted in the context of PRG serum levels.

Limitations, reasons for caution: Since in the dataset, only data regarding frozen embryo transfers were included, fresh ETs need to be explored further. The model was based on endocrinal markers as measured on day six after ET hence it cannot be used to interpret those markers as measured on any other date.

Wider implications of the findings: In order to most accurately inform patients regarding the possible outcomes of embryo-transfers, practitioners should not limit themselves to monitoring β-hCG serum levels but also include PRG as an important prognostic of clinical pregnancy.

INVITED SESSION
SESSION 28: THE ROLE OF ENDOCRINE DISRUPTOR CHEMICALS IN REPRODUCTION

Monday 26 June 2023 Hall D3 17:00 - 18:00

Abstract citation ID: dead093.109
O-090 Endocrine disruptors

J. Flaws[1]

[1]*University of Illinois Urbana-Champaign, Comparative Biosciences, Urbana, U.S.A.*

Female mammals, including women, are exposed to endocrine disrupting chemicals (EDCs) on a daily basis. This is of concern because many EDCs inhibit ovarian follicle growth and steroidogenesis, processes that are critical for maintaining female fertility. Our research focuses on the effects of EDCs known as phthalates on female fertility. Phthalates are of interest because they are ubiquitous synthetic chemicals used as plasticizers and stabilizers in a myriad of consumer products, including everything from shower curtains to children's toys to cosmetics and personal care products such as perfumes, nail polish, deodorants, and lotions. Phthalates are also used in pesticides, wood finishes, adhesives, solvents, lubricants, defoaming agents, and in medical devices including tubing, blood bags, surgical gloves, and dialysis equipment. Despite the widespread use of phthalates and ubiquitous human exposure, limited information is available about the effects of environmentally relevant phthalate mixtures on female reproduction. Thus, we tested the hypothesis that prenatal exposure to an environmentally relevant phthalate mixture affects female reproduction in the F1, F2, and F3 generations of mice. To test this hypothesis, pregnant CD-1 mice were orally dosed with vehicle control (corn oil) or a phthalate mixture (20μg/kg/day-500mg/kg/day) daily from gestational day 10 to birth. The mixture was based on urinary phthalate metabolite levels measured pregnant women in the United States, and consisted of 35% diethyl phthalate, 21% di(2-ethylhexyl) phthalate, 15% dibutyl phthalate, 15% di-isononyl phthalate, 8% diisobutyl phthalate, and 5% benzylbutyl phthalate. Adult F1 females born to these dams were used to create the F2 generation by mating them with unexposed males and F2 females were used to create the F3 generation by mating them with unexposed males. At selected times, estrous cyclicity and fertility indices were monitored and ovaries and sera were collected for analysis. Our data indicate that prenatal exposure to the phthalate mixture significantly decreases anogenital distance, testosterone levels, and litter size, but it significantly increases abnormal estrous cyclicity, uterine weight, the number of cystic ovaries, follicle-stimulating hormone levels, and luteinizing hormone levels compared to control in the F1 generation. Further, our data indicate that prenatal exposure to the phthalate mixture increases body weight, uterine weight, the number of cystic ovaries, and time to pregnancy and it decreases testosterone levels compared to control in the F2 generation. In addition, our data indicate that prenatal exposure to the phthalate mixture increases body weight, uterine weight, the number of cystic ovaries, and abnormal cyclicity and it decreases anogenital distance and the number of live pups compared to control in the F3 generation. Collectively, these data suggest that prenatal exposure to an environmentally relevant mixture of phthalates adversely affects reproductive

function in a multi- and transgenerational manner in female mice. These findings have increased our understanding of the mechanisms by which EDCs cause female reproductive toxicity. This information eventually may lead to the development of novel targets for the prevention or treatment of infertility induced by EDCs.

Since more than 40 years, there are annual increasing of studies, meta-analysis reporting and discussing the potential associations between endocrine disrupting chemicals (EDCs) and human fertility potential declining. Today it's accepted that a substantial number of environmental and exposition factors affect the fertility and fecundity capacity of couples during the peri and post conception period. It's accepted that most of EDCs interfere with or mimic steroid hormone action; predominantly by affecting estrogen, androgen and thyroid hormones signaling pathways and disturbing specific molecular process on relation with single or multiple biological functions.

Some of EDCs can interact with the male and female reproductive system and lead to endocrine disruption in the testis and ovary. they exert their effects mainly via binding transcription factor receptors, EDCs can alter endocrine function through a variety of mechanisms. At fertility age EDCs may alter the expression and/or activity of enzymes required for synthesis and/or catabolism of testicular and ovarian sex steroids and the expression of hormone receptors and/or their ability to bind their and endogenous ligands.

For example, in male, the literature reported a negative correlation between disrupted spermatogenesis and lifestyle factors (environmental-professional expositions) such as alcohol consumption, cigarette smoking, drug use, and obesity caused by high-energy diet. In female infertility diseases, the negative impact of chemicals ED has been studied in animals. Many disorders have been described, such as low ovarian weight, impaired folliculogenesis, a high aneuploidy rate and the acceleration of follicular atresia. Indeed, women exposed to some endocrine-disrupting pesticides (such as atrazine, lindane) have an elevated risk of long menstrual cycles or anovulation but the most serious consequence is POF and endometriosis pathophysiology's.

In our IVF experience in Picardie region (France), we observed that various pesticides with an endocrine-disrupting action are associated with poor oocyte quality (maturation and competency), embryonic defects and poor IVF outcomes, and some pesticide compounds are linked to specific causes of female infertility, such as premature ovarian insufficiency, polycystic ovarian syndrome, and endometriosis. It was reported that EDCs can reduce embryo implantation chances and increase miscarriage, placenta and post-natal abnormalities. for endometrium receptivity and implantation failure EDCs can play by modifying keys elements of the immune response relevant to pregnancy, and disrupt immune tolerance required for robust placentation, optimal fetal development and be a as contributing risk factors in recurrent miscarriage, preeclampsia, preterm birth and related pathologic gestation

Environmental insults, including endocrine disrupting chemicals during critical periods of fetal development, can alter DNA methylation patterns, leading to inappropriate developmental gene expression and disease risks. Similar to environmental factors, endocrine-disrupting chemicals can influence gene expression without modifying the DNA sequence. It is commonly accepted that the transgenerational inheritance of parentally acquired traits is conveyed by epigenetic alterations risks also known as "epimutations".

In Conclusion, the negative impact of exposure to various endocrine-disrupting is becoming now a worldwide public health. Indeed, the community should be informed about the fertility decline, low ongoing pregnancy rates, and elevated risk of miscarriage associated with exposure to high doses of pesticides for example. We must keep in mind that humans are exposed to EDCs mixtures composed of hundreds of chemicals every day and not a single chemical in isolation.

Abstract citation ID: dead093.111
O-092 Does embryo biosensing really determine endometrial fate decisions at implantation?

J. Brosens[1]

[1]Warwick Medical School, Division of Biomedical Sciences, Coventry, United Kingdom

Implantation depends on bi-directional communication between the blastocyst and endometrium. Encoded in this communication is information on maternal and embryonic fitness, which in turn can lead to the activation of species-specific reproductive suppression mechanisms. For example, blastocysts in over 130 mammals, although not humans, respond to the presence or absence of specific endocrine or endometrial cues by entering or exiting diapause, a state of suspended animation that leads to postponement of implantation. By contrast, embryo biosensing and selection depend on the endometrium first receiving and decoding fitness information from the conceptus and then either promoting implantation or initiating rapid tissue breakdown, thus limiting maternal investment into a failing pregnancy. Importantly, embryo selection relies on physiological mechanisms that sense deleterious (internal/external) cues, which is fundamentally different from reproductive failure caused by disease or trauma. Nevertheless, physiological embryo selection is easily conflated with pathology. For example, repeated implantation failure of low-fitness IVF embryos can lead to the diagnosis of 'recurrent implantation failure', an ill-defined clinical label, which often spurs uninformative investigations and ineffective ad-hoc treatments. On the other hand, pathological relaxation of embryo selection at implantation causes early pregnancy loss, with the frequency of affected cycles determining the age-independent recurrence risk of miscarriage. In this presentation, I will elaborate on the cellular mechanisms that control embryo biosensing and selection, highlight the clinical consequences, and discuss emerging strategies for pre-pregnancy optimisation of the endometrium.

O-093 Endometrium-blastocyst cross talk: how far are we from understanding?

L. Campagnolo[1]

[1]*University of Rome TorVergata, Biomedicine and Prevention, Roma, Italy*

The early events characterising implantation of the human embryo represent a critical step in which proper activation of orchestrated molecular pathways regulate the success of pregnancy. Understanding this complex network is considered by many the last frontier of human reproduction. Although outstanding research advancements have provided clinicians tools to select the best quality embryo, identification of the optimal timing in which the endometrium is ready to accommodate it remains a challenge. Over the last decade several studies have identified many key players involved in the preparation of the endometrium to implantation and several diffusible signals guiding the embryo in its journey toward the maternal endometrial tissue have been uncovered (Massimiani et al. 2020). However, pieces of the puzzle are still missing.

For convenience, the process of implantation is subdivided into several sequential processes, the completion of one being propaedeutic to the following. Once the blastocyst has arrived in close proximity to the uterine epithelium, the first event occurring is its escape from the zona pellucida. The molecular basis of blastocyst hatching remains poorly understood, and species-specific differences have been reported. Using the mouse model, we recently demonstrated that thyroid hormone up-regulates the expression of specific lytic enzymes (Isp1 and Isp2) known mediators of mouse embryo zona lysis. Interestingly, we observed that TH-mediated upregulation of Isp1 and Isp2 is strictly dependent on the presence of endometrial stromal cell feeder layer, clearly indicating that blastocyst–endometrium interaction is indispensable for TH-mediated increased expression of these proteases. So far, no molecular signals regulating hatching in humans have been identified, and only mechanical forces have been proposed to induce zona opening; however very recently the possibility that proteases may be involved also in humans has been suggested (Almagor et al., 2020), although further studies are needed to support this hypothesis.

Once free from the zona, the embryo contacts the endometrial epithelium and starts its journey to further proceed in the consolidation of pregnancy. Hormones, pro- and anti-inflammatory mediators, growth factors and their receptors, adhesion molecules, and proteases and protease inhibitors have been reported in the regulation of the process of embryo apposition, adhesion, and invasion (Massimiani et al., 2020). Among the many molecular signals, the Notch pathway has been recognized key in embryo-endometrium cross talk (Cuman et al., 2014). Transient activation of the Notch1 receptor has been demonstrated in the process of decidualization (Afshar et al., 2012), a limiting step to implantation, and blastocyst-conditioned medium has been shown to induce the expression of Notch family members in decidual cells (Hess et al., 2007). Expression of notch receptors and ligands has been reported in the blastocyst trophectoderm as well (Cuman et al., 2014). We previously demonstrated that the secreted factor epidermal growth factor-like domain 7 (EGFL7) is a novel modulator of the Notch pathway, it is expressed by trophoblast cells of the mouse blastocyst (Fitch et al., 2004; Lacko et al., 2014) and it regulates human trophoblast migration and invasion ability by activating the Notch pathway (Massimiani et al., 2015). Data will be presented demonstrating that EGFL7 is expressed in the human endometrium and its expression is mainly localized in the glandular epithelium throughout the menstrual cycle. EGFL7 is significantly upregulated in whole endometrial tissue during the secretory phase, particularly in the stromal compartment; this observation is further supported by in vitro studies showing its upregulation in decidualized endometrial stromal cells, suggesting a role for EGFL7 in implantation. Further support is provided by the evidence that its levels are strongly downregulated in the endometrium of women with impaired fertility. We propose EGFL7 as a novel player involved in the embryo-endometrium cross talk.

INVITED SESSION

SESSION 30: POLYCYSTIC OVARY SYNDROME: A REVISIT

Abstract citation ID: dead093.113
O-094 Management of subfertility in women with PCOS: expectations, problems and solutions

R.J. Norman[1], **M. Costello**[2]

[1]*University of Adelaide, Robinson Research Institute- NHMRC CRE WHiRL, Tranmere- SA, Australia*
[2]*University of New South Wales, Obstetrics and Gynaecology, Sydney, Australia*

Polycystic ovarian syndrome (PCOS) is a common cause of subfertility particularly when anovulation is present. In this circumstance efforts are made to induce ovulation through lifestyle modification, medication, or a combination of both. Other patients with PCOS may be ovulatory but require IVF/ICSI for other causes, including male factor or tubal infertility. In all cases, attention needs to be placed on the underlying metabolic, psychological, and reproductive features that may complicate treatment and subsequent pregnancy. Pregnancy itself has a higher chance of complications and these can be reduced by adequate preconception evaluation and intervention.

Recently, the international evidence-based guideline for evaluation and treatment of PCOS has been updated (1) and the infertility section subjected to a literature integrity check to exclude publications that did not meet the highest criteria for incorporation into clinical management. A recent individual patient data meta-analysis has also clarified the relative efficacy of fertility treatments (2). The following conclusions are recommended;

1. Letrozole is the first line drug of choice for ovulation induction based on its efficacy and lower multiple pregnancy rate
2. Clomiphene is an effective drug particularly given a long experience of use and its lower cost
3. Metformin may be valuable for some patients particularly if glucose intolerance is present
4. A combination of clomiphene and metformin may be effective, particularly in overweight individuals
5. Gonadotrophins are an effective treatment in experienced clinics which the resources to undergo adequate monitoring
6. Laparoscopic ovarian surgery may assist some patients and is associated with a lower multiple pregnancy rate and may have long term benefits
7. IVF may be safely conducted with appropriate safeguards to reduce ovarian hyperstimulation syndrome in those where ovulation induction has failed.

It should be noted that some of these drugs are “off-label” in many countries and are not recommended in several healthcare systems.There are several areas where further information may lead to altered and improved practice:

1. IVF as a first line therapy may be more effective and allow better control of multiple pregnancy rates.
2. In vitro maturation (IVM) with IVF/ICSI shows increasing success with no or minimal FSH use (3).
3. Bariatric surgery is more readily available and may lead to significant weight loss related ovulation.
4. Newer GLP1 receptor agonists show dramatic weight loss and are being evaluated in PCOS.
5. First line gonadotrophin treatment has been advocated by some proponents.
6. Higher dose and longer use of standard oral agents may help in ovulation induction resistant patients.
7. Inositol and myoinositol are being evaluated as safe, low cost, over the counter alternatives.
8. Alternatives to hCG are available for ovulation induction in oral and IVF cycles.

9. Promising pharmacogenomic approaches may allow individualisation of treatment.

While the genomic and environmental aetiology of PCOS remains uncertain, the increasing emphasis on evaluation and assessment of effective therapies for subfertility is advancing rapidly.

O-095 Different phenotypes of PCOS: Implications to clinical practice

S. Franks[1]

[1]*Imperial College London, Institute of Reproductive & Developmental Biology, London, United Kingdom*

Polycystic ovary syndrome (PCOS) is a very common, heterogeneous syndrome which presents with a spectrum of clinical and biochemical features. It is associated with both reproductive and metabolic dysfunction and has a negative impact on long term health, including mental health. Although there appears to be a common genetic background to PCOS, regardless of presentation, environmental factors, including diet, play an important part in determining the phenotype. The most commonly used diagnostic criteria, the Rotterdam criteria, takes account of the heterogenous nature of the syndrome but the spectrum of presentation can be categorised as four clinical and biochemical subtypes which comprise (A) ovulatory dysfunction, hyperandrogenism, polycystic ovaries (PCO), (B) ovulatory dysfunction, hyperandrogenism but without PCO, (C) hyperandrogenism without ovulatory dysfunction but with PCO and (D) ovulatory dysfunction with PCO but without hyperandrogenism. These are not rigid categories since some women may go from one to another, for example weight gain may lead to anovulation in a woman who previously had hirsutism but regular cycles. Nevertheless, the diagnostic sub-category has a significance influence on clinical management.

Women who have both hyperandrogenism and ovulatory dysfunction (A&B) are at higher risk of metabolic dysfunction which is exacerbated by obesity (and carries a high long-term risk of diabetes and cardiovascular disease) and so merit thorough investigation which includes assessment of glucose tolerance and lipids. Those who have predominantly ovulatory problems may require fertility treatment or regulation of menses but some who simply have irregular menses may need no specific treatment. Symptoms of hyperandrogenism (hirsutism, acne, alopecia) can be particularly distressing and may be best managed in collaboration with a dermatologist. The negative impact of PCOS on mental health is a very common problem, the high prevalence of which has only recently been appreciated. Not surprisingly, it is particularly relevant in those women who have moderate to severe symptoms of hyperandrogenism.

In summary, PCOS is a syndrome characterised by a variety of symptoms and endocrine abnormalities and it is important to tailor treatment individually, according to the need for symptom relief and with regard to concerns about long-term health.

Study question: What is the predictive value of using Day-3 (D3) embryo morphology and clinical factors to identify good quality euploid blastocysts?

Summary answer: Using a machine-learning model, D3-cell count and fragmentation helps identifying embryos most and least likely to develop into euploid blastocysts.

What is known already: It is well-known that the pattern of embryo cleavage affects blastocyst ploidy. Less has been elucidated in relation to embryo fragmentation. Published studies often used outdated biopsy techniques (D3-biopsy) and obsolete genetic technologies (FISH). Hence, the association between embryo fragmentation and ploidy status remains controversial. Existing hypothesis is that embryo fragmentation is a regulation event to maintain homeostasis and normalize genetic constitution. Literature is lacking studies investigating this association using newer genetic technologies such as Next Generating Sequencing (NGS). Moreover, a predictive model using D3-embryo characteristics and clinical factors can be useful for triage of laboratory resources.

Study design, size, duration: Retrospective observational single center study including 34781 embryos from 5701 cycles, between March 2017 and March 2020. Embryos were evaluated for degree of fragmentation and cell number on D3, 68 ± 1hrs post insemination. Female Age, AMH and BMI were annotated as patient characteristics. All blastocysts available on D5 or D6 with a quality ≥ BL3CC (n = 18361) were subjected to trophectoderm (TE) biopsy for Preimplantation-Genetic-Testing for aneuploidies (PGT-A) analysis with Next-Generation-Sequencing and ploidy rates were recorded.

Participants/materials, setting, methods: Degree of fragmentation was classified as follows: A(<=10%), B(11-25%), C(26-35%), D(>35%). Data on embryo fragmentation was stratified according to cell number category: <6cells, 6-10 cells, >10 cells and compacted stage. Morphology markers (cell-count and fragmentation rate), along with patient characteristics (age, anti-Mullerian hormone and body-mass index) was modeled using a gradient-boosting decision tree algorithm. Performance of the machine learning (ML) model was assessed with AUC values, calibration curves after partitioning the dataset 1:1 for training/validation.

Main results and the role of chance: Day-3 embryos consisting of < 6 cells (n = 5926), 6-10 cells (n = 23920), and >10 cells (n = 1612) were included, along with 3323 compacted embryos. The rate of good-quality blastocysts decreased with higher fragmentation rates (38.2%, 14.8%, 4.6%, and 1.6%, A, B, C, and D, respectively; P < 0.001). Day of biopsy was earlier for embryos with lower fragmentation rates (Day-5 biopsy: 24.2%, 9.7%, 4.0%, and 0.0%, P < 0.001). Among the biopsied blastocysts, euploidy rates were similar at 44.9%, 43.0%, 42.7%, and 66.7% in groups A vs B, C, and D, respectively (P = 0.075, 0.350 and 0.141). When stratified by cell number, euploidy rates were lowest in blastocysts derived from <6-cells, at 33.5%,

34.3%, 26.9%, and 50.0% in groups A vs B, C, and D, respectively (P = 0.803, 0.185 and 0.394).

The best performance ML model was provided by using fragmentation % and cell count along with female age, BMI and AMH. This resulted in a modest predictive accuracy for predicting euploid embryo development (AUC: 0.72, 95% CI: 0.71 to 0.73). The model was well- calibrated and correctly assessed the probability of D3-embryos developing into euploid blastocyst. For instance, embryos with a predicted probability of ≤ 2.5% rarely developed into euploid blastocyst (actual rate: 2.6%) and model had a predictive value of 97.4%.Limitations, reasons for caution:

The retrospective nature of the study and inter-observer variability in D3-embryo fragmentation scoring is a limitation. Nevertheless, embryologists performing the embryo scoring followed the same SOPs. Findings need to be validated in external cohorts.

Wider implications of the findings: The model can utilize clinical factors and D3-embryo morphology markers to estimate the probability of a D3-embryo developing into an euploid blastocyst. This model can be useful for patient information, mainly when a decision on embryo selection for PGT-A needs to take place.

O-097 Predicting live birth rate using combined Day3-spent embryo culture medium metabolomics and cumulus cell gene expression based algorithm to optimize embryo selection in unexplained infertility

R. Chattopadhyay[1], I. Mitra[2], S. Sharma[3], G. Bose[3], S. Ghosh[4], S. Kalapahar[3], K. Chaudhury[2], P. Chakraborty[3]

[1]Institute of Reproductive Medicine, ART, Calcutta, India
[2]Indian Institute of Technology- Kharagpur, School of Medical Science and Technology, Kharagpur, India
[3]Institute of Reproductive Medicine, Department of Assisted Reproduction, Kolkata, India
[4]Institute of Reproductive Medicine, Department of Assisted Reproduction, Calcutta, India

Study question: Can combination of metabolomics of spent embryo culture medium (sECM) and cumulus cell (CC) genes judge live birth rate in unexplained infertility (UI)?

Summary answer: A combination of day3 metabolic profiling of sECM with CC gene expression yields an algorithm to predict live birth rate in UI.

What is known already: Optimizing embryo selection is rate-limiting for pregnancy success. The metabolomic profile of sECM can aid in advanced prediction of embryonic developmental potential. Recent transcriptomics studies proposed prokinectin 2 (PROK2), and pregnancy up-regulated nonubiquitous CaM kinase (PNCK) as two novel gene/s responsible for perifollicular vascularization and embryonic development respectively; two important events regulating bidirectional CC-oocyte signalling and implantation ability. Given that UI is contributory to impaired oocyte quality, we delineated if combined metabolic signature of CC gene expression encompassing metabolic, developmental competence, and extracellular matrix facet/s and sECM could address live birth rate in women with UI following single embryo transfer.

Study design, size, duration: A prospective cohort study was conducted at Institute of Reproductive Medicine between January 2022 and October 2022. 48 women (age: 30-39 years) diagnosed with UI undergoing oocyte-retrieval offered consented participation and were sub-stratified according to pregnancy outcome. Cleavage-stage embryos from intra cytoplasmic sperm injection (ICSI) cycles were scored according to combination of gene expression pattern of CC-samples and integral value of metabolite obtained from nuclear magnetic resonance (NMR) spectroscopy of sECM (range 0-3, 4-6, 7-9).

Participants/materials, setting, methods: Expression profiles of metabolic (LDHA, PFKP, PKM2), extracellular matrix (HAS2, PTX3, TNFAIP6, VCAN), and developmental competence (PNCK, PROK2) related genes were evaluated by real time-quantitative polymerase-chain-reaction (qRT-PCR) from retrieved CC. Day-3 sECM (30 μL) was collected for NMR from 43 single transferred embryos. Univariate and multivariate analysis was performed after NMR data acquisition. Live birth rate was evaluated by area-under-the-curve (AUC) values using combined score panel.

Main results and the role of chance: The groups were similar for patient age, BMI, AMH, infertility diagnosis, and stimulation protocol. A total of 43 cycles were included in the analysis [embryo transfer cancelled (n = 2), insufficient cumulus mass (n = 3)]. Clinical pregnancy was confirmed in 16 patients (37.21%). Mean mRNA levels for all genes were similar in CC associated with oocyte that fertilized normally (2PN) compared with those that either failed to fertilize or were abnormal (i.e. 1PN, 3PN). Similar results were observed in terms of speed of embryonic cleavage (≥7 cell on Day 3 vs. ≤6 cell on Day 3). Expression of VCAN, (OR: 1.102, 95% CI: 1.010-1.202, $p < 0.02$), PNCK (OR: 0.931, 95% CI: 0.916-0.947, $p < 0.001$) and PROK2 (OR: 1.273, 95% CI: 1.011-1.231, $p < 0.001$) was significantly higher ($p < 0.01$) in CC that achieved live birth compared with those that failed to result a successful pregnancy. Multivariate and univariate analysis revealed distinct metabolomic signatures between pregnant and non- pregnant group/s. Lactate, pyruvate and proline were the most significant ($p < 0.01$) altered metabolite in sECM of non-pregnant group when compared to their pregnant counterpart. The combination demonstrated a "good" (VCAN, pyruvate: AUC: 0.87), "fair" (PROK2, proline: AUC: 0.79) and "modest" (PNCK, glucose: AUC: 0.71) in terms of live-birth rate.

Limitations, reasons for caution: The study population is heterogeneous in terms of duration of infertility and previous infertility treatment outcome, limited by small sample size and subjective nature of embryo scoring. The presumable involvement of unknown factors in developmental competence of UI and impact of frozen cycle/s should also be addressed.

Wider implications of the findings: The study provides reliable accuracy measures to support relationship between live birth rate and combined score panel in patients with UI. It is envisioned integration of CC gene expression/s and metabolomics of sECM if combined with patient characteristics may tailor therapy by artificial intelligence to model the outcome in UI.

Trial registration number: Not applicable

O-098 Improved pregnancy rates following day 5 eSET with early hatching/hatched blastocysts (116-118 hours) compared to expanded blastocysts in a strictly selected cohort: a prospective study

B. Ghoshdastidar[1], S. Ghoshdastidar[2]

[1]GD Institute for Fertility Research, Reproductive Endocrinology and Infertility, Calcutta, India
[2]GD Institute for Fertility Research, Reproductive Endocrinology and Infertility, Kolkata, India

Study question: To investigate whether blastocysts hatching early on day 5 following IVF are developmentally superior and lead to better clinical outcomes in non PGT-A eSET cycles.

Summary answer: Fresh eSET on day 5 with spontaneously early hatching blastocysts (116-118 hrs) results in significantly better pregnancy rates compared to top quality expanded blastocyst transfers.

What is known already: Most studies seem to indicate that transfer of blastocysts at more advanced stages of development result in higher pregnancy rates. However, most studies comparing results between full/expanded vs hatching/hatched blastocyst transfers are either retrospective, have relaxed inclusion criteria, or perform transfers following assisted hatching or extended culture. Moreover, there appears to be no data on proportion of blastocysts

that spontaneously hatch early on day 5, or how well they perform comparatively. Yet it has been reported that earlier time-points of blastocyst development are associated with higher euploidy. We felt the need for a well-designed prospective study to address these questions.

Study design, size, duration: This prospective study to compare pregnancy rates between early hatching/hatched blastocysts and top quality expanded blastocysts (4 BB or higher) in fresh, non PGT-A eSET cycles took place between October 2021 and October 2022 following institutional ethical clearance. 115 patients<37 years with AMH>1.5 undergoing 1st IVF cycles for tubal, mild male factor, unexplained infertility consented for the study and 94 patients completed it to eSET. Patients with PCOS, endometriosis or previous pelvic surgery were excluded.

Participants/materials, setting, methods: The study was conducted at a tertiary IVF centre. All patients underwent antagonist cycles, egg retrievals and IVF as per standard protocol. Blastocyst culture decision was taken at 2-PN examination. Embryos were examined at 116-118 hours as per our practise and decisions made to exclude from data analysis patients without at least one blastocyst at 4BB or above. eSETs performed at 120-122 hours with hatching/hatched blastocysts where available, expanded blastocysts in others. Luteal support initiated.

Main results and the role of chance: Demographic parameters of the patient cohort such as age (30.79 ± 4.06), BMI (25.53 ± 3.11) and AMH (3.23 ± 1.68) are presented as mean ± SD. Data was analysed using IBM SPSS V.26 statistical package. Differences in pregnancy rates between early hatching/hatched vs expanded blastocyst eSET groups were tested using Z test for proportions at 5% level of significance. Data was analysed for 94 patients of whom 62 had single expanded blastocyst transfers (22 achieved pregnancies) and 32 had eSET with early hatching/hatched blastocysts (of whom 18 became pregnant). 55 out of a total 261 blastocysts in the whole cohort were found to have initiated spontaneous hatching (n = 39) or fully hatched (n = 16) at 116-118 hours post-fertilisation resulting in an early hatching rate of 21.1% per blastocyst. Clinical pregnancy rate (CPR) defined as fetal heartbeat on ultrasound at 6 weeks of gestation and ongoing pregnancy rate (OPR) defined as pregnancy continuing beyond 10 weeks were found to be significantly superior in early hatching/hatched group vs expanded blastocyst group (CPR: 56.3% vs 35.5%, p = 0.002; OPR: 50% vs 30.6%, p = 0.003). Difference between miscarriage rate in the hatching/hatched group (11.1%, n = 2) and expanded blastocyst group (13.6%, n = 3) was not statistically significant.

Limitations, reasons for caution: Our sample size was relatively small in order to rigorously select a homogeneous group of good prognosis patients and adhere to strict study criteria- only 1st cycle, autologous, fresh, non PGT-A, day 5 eSET cycles were included. Larger controlled prospective studies would be valuable to confirm these findings.

Wider implications of the findings: To our knowledge this is the first report of improved pregnancy rates with early hatching blastocyst eSETs compared with expanded blastocysts. Basic science studies may shed more light on the biological underpinnings of these findings. Such transfer strategy may also prove useful to select the best blastocysts in non-PGT-A cycles.

O-099 The inner cell mass (ICM) regions can be used to predict pregnancy with a similar accuracy as the original images of the entire embryo

H.M. Kim[1], T. Ko[2], J.Y. Jung[3], J.H. Park[3], J. Koo[4], S.H. Min[4], M.K. Chung[5], J. Kim[6], H. Lee[7]

Study question: Can clinical pregnancy be accurately predicted using only ICM and TE regions in an embryo microscopy image?

Summary answer: The AI model accurately predicted pregnancy using ICM segmented images with a similar accuracy as using original embryo images.

What is known already: Previous research suggests that ICM and TE are key factors in determining embryo grade and clinical pregnancy. Grad-CAM images on the CNN models in various literature also highlight the significance of ICM and TE regions. However, there have been no studies to compare and assess the importance of the two regions in pregnancy prediction. This study aims to test the significance of each region by evaluating the performance of models after segmenting ICM and TE regions.

Study design, size, duration: We performed a retrospective study of single static images of 2,555 Day 5 blastocysts from seven in vitro fertilization (IVF) clinics between June 2011 and May 2022. The images were collected from standard optical light microscopes and matched with metadata such as pregnancy outcomes. ICM and TE regions were manually labeled and examined by 5 embryologists with over 10 years of experience.

Participants/materials, setting, methods: We defined a positive pregnancy indication as the presence of a gestational sac (G-SAC). We built 4 CNN models using original embryo images ("Original model"), ICM segmented images ("ICM model"), TE segmented images ("TE model") and ICM & TE segmented images ("ICM & TE model"). The performances were measured through 3-fold cross validation.

Main results and the role of chance: In 3-fold cross validation, the mean and the standard deviation of AUROCs were 0.753 ± 0.005 for Original model, 0.733 ± 0.003 for ICM model, 0.724 ± 0.016 for ICM & TE model and 0.690 ± 0.011 for TE model, respectively. The DeLong test showed significant differences between the AUCs of Original model and ICM model (p = 0.01), and ICM model and ICM & TE model (p = 0.0003). Positive correlations were found between prediction values with pearson correlation [Confidence interval] for Original image and ICM model (0.426 [0.343, 0.495]), Original model and ICM & TE model (0.345 [0.266, 0.419]) and Original model and TE model (0.223 [0.140, 0.304]). Original model showed the highest accuracy and TE model was the least accurate as expected. However, it is noteworthy that ICM model outperformed ICM & TE model. Although it is well known that TE plays a significant role in implantation, forcing the model to utilize both ICM and TE to predict pregnancy could have muddled the analysis. This study proved that pregnancy can be successfully predicted using ICM regions only as well as original embryo images.

Limitations, reasons for caution: This study has limitations due to its retrospective nature, using embryo images from seven IVF centers. Further study with a larger dataset is warranted to offset the differences in focus, magnification and color of embryo images.

Wider implications of the findings: We showed that the AI model using ICM segmented images predicted pregnancy with a similarly high accuracy as using original embryo images. However, the model using TE segmented images showed the lowest performances. Utilizing well-focused ICM images may enhance the performance of pregnancy prediction models.

Trial registration number: not applicable

INVITED SSESSION

SESSION 32: GUIDELINES SESSION: CHALLENGES IN ART, CAN ESHRE GOOD PRACTICE ADVISE BE OF ANY HELP?

Monday 26 June 2023 Hall D5 17:00 - 18:00

O-100 Recurrent implantation failure

N. Macklon[1], D. Cimadomo[2], MJ. de los Santos Molina[3], G. Griesinger[4], G. Lainas[5], N. Le Clef[6], DJ. McLernon[7], D. Montjean[8], B Toth[9], N. Vermeulen[6]

[6]ESHRE central office (no dept), Strombeek-Bever, Belgium
[7]Institute of Applied Health Sciences, School of Medicine Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, UK
[8]Fertilys Fertility centers, Laval & Brossard, Canada
[9]Gynecological Endocrinology and Reproductive Medicine, Medical University Innsbruck, Innsbruck, Austria

Study question: How should Recurrent Implantation Failure (RIF) in ART patients be defined and managed?

Summary answer: This is the first ESHRE good practice recommendations paper providing a definition for RIF and guidance on how to investigate causes and contributing factors and how to improve the chances of a pregnancy.

What is known already: RIF is a challenge in the ART Clinic, with a multitude of investigations and interventions offered and applied in clinical practice, often without biological rational or unequivocal evidence of benefit.

Study design, size, duration: This recommendations document was developed according to a predefined methodology for ESHRE good practice recommendations. Recommendations are supported by data from the literature, if available, the results of a previously published survey on clinical practice in RIF and the expertise of the working group. A literature search was performed in PubMed and Cochrane focusing on "recurrent reproductive failure", "recurrent implantation failure" and "repeated implantation failure".

Participants/materials, setting, methods: The ESHRE RIF Working Group included 8 members representing the ESHRE Special Interest Groups of Implantation and Early Pregnancy, Reproductive Endocrinology, and Embryology, and completed with an independent chair and an expert in statistics. The recommendations for clinical practice were formulated based on the expert opinion of the Working Group, while taking into consideration the published data and results of the survey on uptake in clinical practice. The draft document was then opened for online peer review to ESHRE members and revised in light of the comments received.

Main results and the role of chance: RIF describes the scenario in which the transfer of embryos considered to be viable has failed to result in a positive pregnancy test sufficiently often in a specific patient to warrant consideration of further investigations and/or interventions. The recommended threshold for the cumulative predicted chance of implantation to identify RIF for the purposes of initiating further investigation is 60%. When a couple have not had a successful implantation by a certain number of embryo transfers and the cumulative predicted chance of implantation associated with that number is greater than 60%, then they should be counselled on further investigation and/or treatment options. This term defines clinical RIF for which further actions should be considered. Nineteen recommendations were formulated on investigations when RIF is suspected, and 13 on interventions.

Limitations, reason for caution: While awaiting the results of further studies and trials, the ESHRE Working group recommends identifying of RIF based on the chance of successful implantation for the individual patient or couple and to restrict investigations and treatments to those supported by a clear rationale and data indicating their likely benefit.

Wider implications of the findings: This paper provides good practice advise, but also highlights the investigations and interventions that need further research. This research, when well-conducted, will be key to making progress in the clinical management of RIF.

Study funding and competing interest(s): Yes.

The other authors had nothing to disclose.

[13]Fertility Clinic- Rigshospitalet- Copenhagen University Hospital, Department of Fertility, Copenhagen, Denmark

Study question: Which laboratory based add-ons are effective and safe to use in ART treatment?

Summary answer: In total, more than thirty recommendations were formulated on the use of add-ons, with about a third being laboratory based tests or interventions

What is known already: Treatment add-ons are defined as not essential for the treatment, but optional additional treatments that are sometimes offered on top of routine fertility treatment. There are a wide range of treatment add-ons available, including diagnostic tests, drugs, equipment, holistic or alternative therapies, laboratory and surgical interventions, all claiming to potentiate the effect of the treatment and/or to lessen side effects, improve pregnancy or live birth rate, reduce the risk of miscarriage or shorten the time to pregnancy. Add-ons and can be at extra cost (or not), and evidence on efficacy and safety is often missing. Presumably they can be both beneficial or non-beneficial, as there may be absence of evidence to either.

Study design, size, duration: The ESHRE working group for good practice recommendations on add-ons in ART has produced recommendations useful for professionals, patients and policy makers. More than 30 add-ons were identified, and evaluated for efficiency and safety, and wherever possible also for cost. The literature was identified in a systematic search, reviewed and critically appraised. In the absence of any clear scientific evidence, judgement was based on the professional experience and consensus of the multidisciplinary development group. The guidelines are thus based on the best available evidence and expert agreement. Prior to publication, the guidelines were reviewed by independent international reviewers.

Participants/materials, setting, methods: Interventions were characterized in three sections: 1) Diagnosis and diagnostic tests, 2) Laboratory tests and intervention, and 3) Clinical management. Outcomes were efficacy (pregnancy or live birth rate), risk of miscarriage, time to pregnancy, cost, and safety/risk aspects. Some examples of add-ons in the group of laboratory tests and interventions are oocyte and sperm activation, mitochondria load

and transfer, sperm selection, assisted hatching, genetic testing and addition of hyaluronic acid to media.

Main results and the role of chance: The guideline development group formulated more than 30 recommendations. This lecture will focus on the rationale and the recommendations of the laboratory add-ons currently used in fertility clinics. We will discuss the potential beneficial effects on the IVF treatment, its efficacy, and its safety. While most add-ons are not recommended for the general population of ART patients, where specific patient populations might benefit, indications were formulated.

The guideline has been in stakeholder review and is prepared for submission in 2023.

Limitations, reason for caution: Of the recommendations, none are based on high quality evidence and only a few are based on moderate quality evidence. Hence 90% of the recommendations are supported only by low quality RCTs, observational data, professional experience, or consensus of the development group.

Wider implications of the findings: These recommendations aim to provide guidance to health care professionals and laboratory experts in the field of reproductive medicine, to help towards safe and efficient ART treatments for patients where they can participate in informed decision making with realistic expectations and be fully informed about their chances to pregnancy and live birth.

Study funding and competing interest(s): All costs relating to the development process were covered from ESHRE funds. There was no external funding of the development process or manuscript production.

Study question: Which add-ons are effective and safe to use in the ART clinic?

Summary answer: More than thirty recommendations were formulated on the use of add-ons in diagnosis and diagnostic tests, laboratory tests and intervention, and clinical management.

What is known already: Treatment add-ons are not essential for the treatment but optional additional treatments that are sometimes offered on top of routine fertility treatment. There are a wide range of treatment add-ons on offer including tests, drugs, equipment, holistic or alternative therapies, laboratory and surgical interventions, but consistently, they aim to potentiate the effect of treatment or to lessen side effects herein improve pregnancy or live birth rate, reduce the risk of miscarriage or shorten the time to pregnancy. Evidence on whether some treatment add-ons are effective and safe is often missing or absent. Add-ons can be proven or evidence-based (or not) and can be at extra cost (or not), presumable they can be both beneficial and non-beneficial, as there may be absence of evidence to either.

Study design, size, duration: The ESHRE working group for good practice recommendations on add-ons in ART has produced recommendations useful for professionals, patients and policy makers and identified more than 30 add-ons and evaluated each one of them for efficiency and safety and wherever possible also costs. The literature was identified in a systematic search, was reviewed and critically appraised. In the absence of any clear scientific evidence, judgement was based on the professional experience and consensus of the development group. The guidelines are thus based on the best available evidence and expert agreement. Prior to publication, the guidelines were reviewed by independent international reviewers.

Participants/materials, setting, methods: Interventions were characterized in three sections: 1) Diagnosis and diagnostic tests, 2) Laboratory tests and intervention, and 3) Clinical management. Outcomes were efficacy (pregnancy or live birth rate), risk of miscarriage, time to pregnancy, costs, and safety/risk aspects. This lecture will focus on the recommendations relevant for the ART clinic including endometrial receptivity tests, assisted hatching, freeze-all (elective), ICSI (elective), uterine flushing and endometrial scratching.

Main results and the role of chance: The multidisciplinary development group formulated more than 30 recommendations. This lecture provides a summary of the recommendations of the add-ons currently used in fertility clinics. First it is described how an add-on is hypothesized to have beneficial effects on the IVF treatment, its efficacy, and its safety. While most add-ons are not recommended for the general population of ART patients, indications were formulated where specific patient populations might benefit.

The guideline has been in stakeholder review and is prepared for submission in 2023.

Limitations, reason for caution: Of the recommendations, none are based on high quality evidence and only a few are based on moderate quality evidence. Hence 90% of the recommendations are supported only by low quality RCTs, observational data, professional experience, or consensus of the development group.

Wider implications of the findings: These recommendations provide guidance to health care professionals and laboratory experts in the field of reproductive medicine, and will help towards safe and efficient ART treatment, where patients can participate in informed decision making with realistic expectations and are fully informed about their changes to pregnancy and live birth.

Study funding and competing interest(s): All costs relating to the development process were covered from ESHRE funds. There was no external funding of the development process or manuscript production.

The authors have stated their conflicts of interest if any.

P-563 Efficacy of a brief decisional support intervention on the decision conflict and psychosocial aspects among women with IVF failure: a randomized controlled trial

D. Guo[1], C.H.Y. Chan[1], X.H. Wang[2]

[1]The University of Hong Kong, Social Work and Social Administration, Hong Kong, Hong Kong
[2]The University of Hong Kong-Shenzhen Hospital, Reproductive Medicine and Prenatal Diagnosis Center, Shenzhen, China

Study question: Is decisional support intervention (DSI) efficacious in reducing decisional conflict and improving mental health for women experiencing unsuccessful IVF treatment?

Summary answer: Compared to controls, DSI statistically significantly increased informed decision but not depression symptoms.

What is known already: Failure of IVF treatment could be an unavoidable event and a situation of low control for infertile women. The decisional conflict following unsuccessful IVF treatment could be extremely intense considering the critical issues such as the life goal of childbearing, relationships, finance, etc. Meanwhile, with great importance placed on childbearing, many patients are indulged in the treatment cycles while hesitant to consider ending the treatment or the alternatives, leading to a series of psychosocial problems. Therefore, a decisional support intervention should be considered to facilitate the decision-making and adjustment after unsuccessful IVF treatment.

Study design, size, duration: A multi-centers, two-armed, randomized controlled trial, to assess the efficacy of a decisional support intervention on decisional conflict and psychosocial aspects among women who experienced failure of IVF treatment. Between May 2022 to January 2022, a total of 80 participants were randomly allocated to the DSI group or waitlist control group.

Participants/materials, setting, methods: Eligible participants were women who have undergone at least one cycle of IVF treatment and failed to achieve clinical pregnancy into treatment. DSI participants received a one-hour decisional support counseling, which focused on the discussion about the pros and cons in relation to continuation and termination of treatment, family building alternatives as well as their implications. The participants completed questionnaires before treatment (T0), and after the treatment (T1). Analyses included paired sample t-tests and ANOVA.

Main results and the role of chance: 40 subjects in the intervention group and 38 subjects in the control group were included in the intention-to-treat analysis. The between-group effect analysis showed a significant time x group interaction in informed decision ($p < 0.05$), meaning that informed decision increased in the intervention group but decreased in the control group over time. There was also a marginally significant increase in perceived behavioral control ($p = 0.06$), as well as a decrease in decisional conflict of uncertainty ($p = 0.08$) and anxiety symptoms ($p = 0.08$).

Limitations, reasons for caution: Considering the decision might be navigated by the treatment outcome, this study only measured the short-term effect after the intervention. Secondly, this study only enrolled women, who were more vulnerable to the risk of treatment failures and take a more active role in decision-making, compared to men.

Wider implications of the findings: Instead of putting efforts on psychosocial intervention aiming at improving the chance of pregnancy, this study provides an efficacious brief counseling approach, tapping on patients' existing cultural values and beliefs, to help patients 'find the way out' following the IVF treatment failures.

P-577 Understanding how healthcare professionals address the educational and emotional needs of patients seeking fertility care: an assessment of challenges and barriers across eight countries

M. Augustyniak[1], M. Kupka[2], G. Coticchio[3], S. Esteves[4], A. Fincham[5], P. Lazure[1], S. Péloquin[1]

[1]*AXDEV Group Inc., Performance Improvement Research Division, Brossard, Canada*
[2]*Ludwig-Maximilians-University, University Medical Center of Obstetrics and Gynecology, Munich, Germany*
[3]*9.baby GeneraLife IVF, Department of Science, Bologna, Italy*
[4]*ANDROFERT and University of Campinas UNICAMP, Andrology and Human Reproduction Clinic, Campinas, Brazil*
[5]*Fertility Europe, Office Management Division, Brussels, Belgium*

Study question: What are the current challenges and barriers preventing healthcare professionals (HCPs) from optimally addressing patients' educational and emotional needs in fertility care?

Summary answer: HCPs lack optimal knowledge of patients' needs/preferences for educational and emotional support, have sub-optimal skills addressing them, and underutilize external resources (e.g., psychologists).

What is known already: Couples who have difficulty conceiving a child can face a turmoil of emotions, including anxiety and distress, especially when external social pressures are at play. All patients seeking fertility care deserve their educational and emotional needs to be heard and addressed, as advocated by The European Society of Human Reproduction and Embryology (ESHRE) guidelines. Nevertheless, a 2015 educational and behavioural needs assessment found that HCPs involved in reproductive medicine perceive their skills to identify the needs of patients for psychological and emotional support to be less than optimal, especially when discussing sensitive or distressing issues.

Study design, size, duration: This exploratory mixed-methods study triangulated data from a qualitative phase (76 interviews, June-August 2021) and a quantitative phase (323 surveys, November 2021). Participants included patients (qualitative phase, n = 28), physicians (both phases, n = 249) and laboratory specialists (both phases, n = 122) using assisted reproductive technologies (ART).

Participants/materials, setting, methods: Countries included Brazil, China, France, Germany, Italy, Mexico, Spain, and UK. Interviews were recorded, transcribed and coded. Thematic analyses were performed. Surveys assessed knowledge, skill, agreement, and task performance frequency using 5-point scales. Knowledge and skill ratings of none (1), basic (2) or intermediate (3), as opposed to advanced (4) or expert (5), were considered a gap. Descriptive analysis and crosstabulations with chi-square tests were performed to explore variations by country and professional role/specialty area.

Main results and the role of chance: Patient interviews indicated a need to improve HCPs' ability to set realistic yet encouraging, expectations about conception outcomes. Underlying barriers to fulfilling this need included a lack of optimal knowledge amongst HCPs regarding patients' preferences, skills addressing their needs, and an under-utilization of resources for psychological support. Survey results indicated 31-36% of physicians and laboratory specialists had a knowledge gap of patients' preferences and needs for education and emotional support; 11-39% of physicians had a skill gap for a) educating their patients about factors contributing to couples' infertility and treatments that can optimize chances of conception/pregnancy; b) setting patient expectations about successful fertility outcomes and next steps; and c) providing emotional support to patients/couples experiencing failure to conceive. For laboratory specialists, 23% reported 'never', 'rarely' or 'sometimes' contributing to patient education. When asked how often they "consult references provided by patient organizations regarding the psychological and emotional needs of patients" and "direct patients to support groups or forums (online or in-person)", an average of 47-49% of surveyed HCPs said 'never', 'rarely' or 'sometimes'. Only 49% of surveyed HCPs reported collaborating with psychologists specialized in infertility. The extent to which gaps affected HCPs varied by country and professional role/specialty area.

Limitations, reasons for caution: Although multiple countries were included in this exploratory mixed-methods study, due to small sample sizes, the likelihood of observing a difference in the frequency of reported challenges, barriers and gaps by country due to chance alone could not be excluded.

Wider implications of the findings: Several years after the publication of the ESHRE guidelines for psychosocial care, challenges related to providing adequate educational and emotional support to patients remain. This study identified opportunities and direction for continuing professional development to promote routine psychosocial care in fertility clinics.

Trial registration number: Not applicable for this mixed-methods self-reported educational needs assessment.

P-578 Interactive Effects of Relationship Satisfaction and Social Support on stress: a dyadic study

M.I. Fernandes[1], M. Martins[1,2], J. Pedro[2,3]

[1]Faculty of Psychology and Education Sciences of the University of Porto, Psychology, Porto, Portugal
[2]Faculty of Psychology and Education Sciences of the University of Porto, Centro de Psicologia UP, Porto, Portugal
[3]Centro de Genética da Reprodução Prof. Alberto Barros, n.a., Porto, Portugal

Study question: Does relationship satisfaction and social support demonstrate actor and partner effects on perceived stress, and is this relationship moderated by reproductive status?

Summary answer: No significant partner effects were found. Relationship satisfaction is related to one's stress. Reproductive status moderates the relationship between one's relationship satisfaction and one's stress.

What is known already: Infertility affects around 15% couples and there seems to be a growing number of couples experiencing infertility. The inability to conceive is experienced by the couple as a stressful situation and should be addressed as a shared problem. Social support seems to be a protective factor for infertility-related stress and correlates directly with individual stress and partner stress among infertile couples. Also, relationship satisfaction has a significant impact on stress and adjustment to infertility, suggesting that low levels of relationship satisfaction predict significant stress levels in infertile women.

Study design, size, duration: This study included 213 heterosexual couples. The participants answered a questionnaire that included self-reported measures for perceived stress, relationship stress and received social support. Data collection was conducted online between October 2016 and October 2018 (detailed information [removed for blind review]).

Participants/materials, setting, methods: This study included 213 heterosexual couples in a relationship, with no children in the current relationship and the women's age was between 20 and 42 years old. Both partners completed the Perceived Stress Scale (PSS), the Relationship Assessment Scale (RAS) and the 2-way Social Support Scale (2-way SSS). Statistical analyses were conducted, and the dyadic analyses were conducted using the Actor-Partner Interdependence Model (APIM) and the Actor-Partner Interdependence Moderation Model (APIMoM).

Main results and the role of chance: A total of 213 couples completed the questionnaire and 45.9% wanted to have children in the future, 8.7% are trying to conceive without an infertility diagnosis and 45.5% received an infertility diagnosis.

None of the partner effects were significant, ($p > .05$), indicating the absence of a significant association between relationship satisfaction and social support from one member and their partner's stress. No significant actor effects were found for neither sex ($p > .05$), regarding social support.

There were significant actor effects for both partners regarding relationship satisfaction, indicating that female and male relationship satisfaction is negatively associated with the stress perceived by one's member (women: $b = -.51$, $SE = .12$, $Z = -4.23$, $p < .001$; men: $b = .45$, $SE = .13$, $Z = -3.60$, $p < .001$).

The reproductive status moderates the relationship between female relationship and female stress ($b = -.31$, $SE = .06$, $Z = -5.41$, $p < .001$, $\beta = -.16$) and also between male relationship satisfaction and male perceived stress ($b = -.26$, $SE = .06$, $Z = 4.30$, $p < .001$, $\beta = -.27$).

Limitations, reasons for caution: The methodological design does not allow inferential causes. The sample may not be representative of the national population, restricting generalizations. Other variables that may have a role in influencing the ones considered, were not included. Only heterosexual couples were considered, which represents a limitation in distinct dynamics.

Wider implications of the findings: Since the romantic relationship can be protective of stress, it becomes relevant that psychological counselling focuses on the quality of marital relationships. It would be ideal for the family planning consultation to inform the importance of both couple members' involvement to screen couples in need of psychological support.

P-581 Family of origin cohesion and intention to pursue fertility preservation in transgender and non-binary people

M. Moura-Ramos[1], A. Pinto[2], J. Reis[2]

[1]Centro Hospitalar e Universitário de Coimbra, Clinical Psychology Unit, Coimbra, Portugal
[2]Universidade Lusófona, Escola de Psicologia, Porto, Portugal

Study question: Is the relationship with the family of origins associated with parenthood plans and fertility preservation of transgender and non-binary people?

Summary answer: Family of origin characteristics, namely family cohesion, is associated with the transgender and non-binary people intention to undergo fertility preservation.

What is known already: Few studies have explored parenting intentions and decision to undergo fertility preservation (FP) in transgender and non-binary people. Most studies have focused on the barriers and facilitators of this decision, focusing on the procedures involved in FP, but no studies have assessed the role or psychological (namely relational) variables in the decision making regarding FP. Previous research indicates that family closeness is an important factor in the psychological adjustment of transgender people. Similarly, research indicates that more favorable family relationships were associated with parenting intentions. No studies have examined how relationship with family of origin may affect fertility preservation intentions.

Study design, size, duration: This is a cross-sectional study. Participants were surveyed online from January to April 2022. Dissemination of the study was performed through the social networks of LGBTQIA+ associations.

Participants/materials, setting, methods: Participants were 69 transgender and non-binary people, aged 18-39. The assessment protocol included a questionnaire assessing childbearing intentions, importance of genetic and non-genetic parental connectedness and intention to pursue FP. A validated measure assessing family relationships (Fertility Environment scale, Moos & Moos, 1976) was used, evaluating family cohesion (degree of commitment and support family members provide for one another) and family expression (the extent to which family members are encouraged to express their feelings directly).

Main results and the role of chance: Participants were 40 transgender men (58%), 8 transgender women (11,6%) and 21 non binary (30.4). About 55,1% participants had already initiated hormonal therapy. Almost half of the sample (47,8%) considered having children in the future, while 13 (18.8%) were sure about not wanting children. Genetic connection was not very important (M = 19.51, from 0 -100). A total of 48,1% indicated that that would envision undergo FP in the future.

A mediational model examining indirect effects were tested to examine whether family of origin relationship (cohesion and expression) would be associated with fertility preservation intention.

A significant indirect effect was found, suggesting that family cohesion is associated with the intention to undergo fertility preservation through the effect on the importance of genetic parenting (estimate: 0.56, bootstrap bias-corrected 95% confidence interval 0.052; 1.199) That is, participants with high family cohesion in their family of origin highly valued genetic parenting and this was positively associated with the intention to undergo fertility preservation.

The same indirect effects was tested regarding family expression, but no significant effects were found, that is, the expression of the family of origin is not associated with the intention to undergo PF (estimate: 0.604, bootstrap bias-corrected 95% confidence interval -0.077; 1.366).

Limitations, reasons for caution: The dissemination of the study and participants recruitment was throughout LGBT+ associations, so it is possible that some transgender people that are less prone to be involved in these associations were not reached.

Wider implications of the findings: The importance of the relationships with the family of origin may be an important factor to consider when counselling transgender and non-binary people regarding fertility preservation This may be markedly important when lower family cohesion may be limiting patients' future options.

[6]*Sunnybrook Research Institute, Obstetrics and Gynecology, Toronto, Canada*
[7]*University of Toronto, Department of Physiology, Toronto, Canada*
[8]*University of Toronto, Institute of Medical Sciences, Toronto, Canada*

Study question: How do the number and location of meiotic crossovers contribute to the formation of aneuploidies observed in preimplantation human embryos?

Summary answer: Normalized across chromosomes, trisomies possess 35% fewer crossovers on average compared to disomies, while the genomic distribution of crossovers is also substantially altered.

What is known already: Meiotic recombination is a crucial source of genetic diversity and is also critical for ensuring the accuracy of chromosome segregation. Understanding the landscape of meiotic recombination, its variation across individuals, and the processes by which it goes awry are long-standing goals in human genetics. Current approaches for inferring the landscape of recombination either rely on population genetic patterns of linkage disequilibrium—capturing a time-averaged view—or direct detection of crossovers in gametes or multi-generation pedigrees, limiting the scale and availability of relevant datasets. Moreover, most of these methods are designed for discovering recombination using data from normal, disomic chromosomes.

Study design, size, duration: We present a method for mapping sex-specific recombination landscapes from low-coverage (<0.1×) data from preimplantation genetic testing for aneuploidy (PGT-A) of embryos with arbitrary ploidy configurations. To overcome the sparsity of these data, our method exploits its inherent relatedness structure, knowledge of haplotypes from external population reference panels, as well as the frequent occurrence of chromosome loss in embryos, whereby the remaining chromosome is phased by default.

Participants/materials, setting, methods: We benchmarked our method by simulating crossovers between known haplotypes. Encouraged by the performance on simulated data we extended our study to retrospective analysis utilizing de-identified PGT-A data obtained between April 2021 and August 2022 at the CReATe Fertility Centre (Toronto, Canada). The data include 20,160 embryos (2,559 IVF patients) with an average depth of coverage of ~0.05×, facilitating the mapping of crossovers at an average resolution of ~150 kbp.

Main results and the role of chance: Our benchmarking results demonstrate high sensitivity and specificity across all ancestries at a coverage of 0.05x per homolog (AUC = 0.989), with AUC declining by 0.014 and 0.053 for when coverage is reduced to 0.025x and 0.013x, respectively. Extending our analysis to real PGT-A data, we observed that our inferred sex-specific landscapes of meiotic crossovers on disomic chromosomes were strongly correlated with published genetic maps from studies based on high-coverage sequencing of parent-offspring trios ($r = 0.86$ for female map; $r = 0.53$ for male map), broadly supporting the accuracy of our method. Notably, the total length of the female genetic map was reduced by 35% for trisomies compared to disomies, consistent with the hypothesized role of reduced crossovers and exchangeless chromosomes in the origins of female meiotic aneuploidy. In addition, the genomic distribution of crossovers is also altered in a chromosome-specific manner. Examples include a reduction in crossovers near the centromere of trisomies versus disomies of chromosome 16, as well as an enrichment of crossovers on the q-arm of trisomies versus disomies of chromosome 22. Together, our results provide a detailed corroboration of the hypothesis that aberrant meiotic recombination contributes to the origins of aneuploidies.

Limitations, reasons for caution: The accuracy of our method is influenced by genomic heterogeneity in depth of coverage, rates of heterozygosity, and mismatches between the ancestry of the reference panel and the tested sequence. Moreover, technical errors such as spurious alignment and genotyping could hinder analysis in repetitive genomic regions.

Wider implications of the findings: Together, our study helps clarify the dual function of meiotic recombination in generating genetic diversity while ensuring meiotic fidelity. Our method for patient-specific mapping of meiotic recombination phenotypes may offer clues about how dysregulation of this process contributes to infertility.

[5]*Koç University Graduate School of Health Sciences, Reproductive Biology, Istanbul, Turkey*
[6]*Koç University School of Medicine, Histology and Embryology, Istanbul, Turkey*

Study question: What are the molecular and physiological effects on human granulosa cells, when **CRISPR/dCas9 epigenome edition technology is efficiently used to increase FSH receptor** (FSHR) activity?

Summary answer: The significant increase in expression of **FSHR maintained by dCAS9 systems has effects on several fundamental cellular events** involving steroidogenic, life-sustaining,cell death related signaling sub-pathways.

What is known already: Manipulation of the expression of FSHR can result in biological events that include fundamental activities of FSH as regulation of folliculogenesis, production of steroidogenic hormones. FSHR can be activated in vitro by FSH analogues, and signaling networks activate ERK1/2 pathway through p38 mitogen-activated protein kinases. CRISPR/dCAS9 can be used to activate or inhibit gene action without silencing the gene. In spite of being used in many systems, interference of FSHR expression by epigenome edition is very **limited** as well as the use of **in vitro tools to increase FSHR expression for investigating IVM, folliculogenesis, PCOS, FSH hyper/hyposensitivity, cancer biology.**

Study design, size, duration: In-vitro cultured HGrC1 (human granulosa cell line) cells were treated by follitropin-alfa (Gonal-f). The experimental groups were designed in triplicates with cells i. without any genome edition and cells that have i. non-targeting gRNA, ii.d**CAS9 activated FSHR**, iii. **dCAS9 activated FSHR and FSH treatment** for 5 min, 15 min, or 1 hr; iv. **only FSH treatment** for 5 min, 15 min or 1 hr. FSHR related gene and protein expressions and estrogen production were evaluated.

Participants/materials, setting, methods: For human FSHR gene, **two separate gRNAs** were designed. Annealing, digestion, ligation,

transformation, colony formation, plasmid isolation, Sanger sequencing analysis, MOI were accomplished for **dCAS9/SAM** system. **HGrC1** (immortalized human granulosa cell line) cells were treated with 75 IU/ml Gonal-f in related groups. After treatment, in triplicates, gene/protein expression for **MTOR, FSHR, AKT, MAPK8, MAPK1, TP 53, CASP 3, ESR1, CYP 19A1** were evaluated by qPCR, WB and IF. **Estradiol** was measured by chemiluminescence immunoassay.

Main results and the role of chance: FSHR has increased significantly in dCas9, dac9 + 5min Gonal-f, dCas9 + 15min Gonal-f, dCas9 + 1h Gonal-f; mostly in 5 min compared to groups without dCas9. The system plasmids did **not show any non-specific effects**.**MAPK1, MAPK8, ESR1, MTOR, AKT, P53** and **CASP3** gene expressions showed significant increase in dcas9 system groups compared to control and NT, whereas in all time-dependent treatments, a significant increase was seen in groups that have dcas9+Gonal-f compared to the ones treated with only Gonal-f. As time dependent manner has been investigated, expressions of **MAPK1, MAPK8 and ESR1 were highest at min 5**, expressions of **CASP and AKT were highest at min 15** and the expression of **MTOR was highest at hour 1**, whereas **FSHR and p53**were strongly expressed at **all time points** ($p < 0.05$ for all mentioned results). Gene expression profiles were also confirmed for P-38 MAPK, AKT, FSHR by WB. IF stainings have revealed higher expression of AKT and MAPK in both dCas9 and dcas9+Gonal-f 5 min compared to the control group, however the intensity of the staining was not satisfactory enough. Interestingly, estrodiol(E2) levels were found to be higher in the 5 minutes only Gonal-f treatment and dcas9 with Gonal-f treatment, while the other groups were similar to control.

Limitations, reasons for caution: -This study has been conducted in **cell line**, rather than primary granulosa cells which are not easy targets for epigenome edition.

-**No testosterone** derivatives were used as substrate for aromatase. This has been reflected in the results as significant increase in FSHR and related genes but non-significant increase in E2 production.

Wider implications of the findings: -dcas9/SAM system can be used efficiently increase **other FSH-receptors**, which is a potent way to reveal molecular sub-pathways in a temporal manner;eg. in **male** reproductive system or in other cells of female RS.

-FSH related conditions as **PCOS** can be examined in vitro.

-**FHSR unresponsive conditions** can be modeled in vitro.

Trial registration number: not applicable

Abstract citation ID: dead093.128

O-105 Chromatin accessibility of oocytes contributes to PCOS transgenerational inheritance

Q. Xie[1], G. Zaixin[2], S. Zhengyi[2], Y. Qi[2]

[1]*Peking Union Medical College Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Medical Research Center, Beijing, China*
[2]*Peking Union Medical College Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Obstetrics and Gynecology, Beijing, China*

Study question: What is the underlying mechanism contributing to the transgenerational defects of oocytes and embryos of polycystic ovary syndrome (PCOS)?

Summary answer: The transgenerational inheritance of abnormal chromatin accessibility in the PCOS oocytes is responsible for the defect of oocytes and embryos in transgeneration.

What is known already: Studies have provided evidence of compromised oocyte quality and related adverse impacts. Observed PCOS animal-model oocyte defects include meiotic abnormalities, mitochondrial dysfunction, and increased oxidative stress. Elevated androgen levels are associated with reduced fertilization rates and lower cleavage rates during in vitro fertilization (IVF) treatment. PCOS could be transgenerationally transmitted, and unique altered gene expression has been observed in metaphase II (MII) oocytes from all offspring in PCOS mice.

Study design, size, duration: We profiled the transcriptome and chromatin accessibility of oocytes and preimplantation embryos in F0-F2 offspring of PCOS mice, to explored whether the inheritance of chromatin accessibility defects in PCOS oocytes was responsible for the abnormalities of oocytes and embryos in PCOS offspring.

Besides, oocytes from 13 healthy women and 8 women with PCOS, 24 blood samples from 24 women with/without PCOS were analyzed to validate the molecular mechanisms of PCOS inheritance.

Duration: 2019.5∼2022.12.

Participants/materials, setting, methods: PCOS mice models were established by means of DHEA-exposure. Smart-seq2 and DNase-seq were utilized to investigate the transcriptome and chromatin accessibility of oocytes and preimplantation embryos in F0-F2 offspring of PCOS mice. Bioinformatic analysis was applied to explore the differential gene expression and chromatin accessibility of oocytes and embryos in PCOS mice and offspring comparing to controls.

Common gene signatures in the tissues of PCOS women and PCOS daughters are analyzed compared to control samples.

Main results and the role of chance: In PCOS mice, we observed transcriptional alteration in oocytes and 2-cell embryos compared to normal mice. There are 4229 and 1197 differentially expressed genes (DEGs) in PCOS oocytes and 2-cell embryos. The DEGs includes both maternal factors and zygotic genome activation (ZGA) genes. Interestingly, in PCOS 2-cell embryos, we observed hundreds of pre-activated genes which are silence in normal 2-cell embryo but expressed in PCOS 2-cell embryos. Notably, many DEGs in the oocytes of PCOS mice were also differentially expressed in the oocytes of F2 PCOS mice compared to control mice, supporting the transgenerational inheritance of transcriptional alteration in PCOS oocytes. Mechanismly, the changes of chromatin accessibility were associated with the DEGs in PCOS oocytes and embryos. In particular, chromatin accessibility of the pre-activated gene promoters is elevated in PCOS oocytes compared to that in normal oocytes. Furthermore, many of the abnormal chromatin accessibility signals detected in F0 PCOS oocytes were also observed in F2 PCOS oocytes. Finally, our data showed that some DEGs in the oocytes of PCOS mice were also differentially expressed in human PCOS oocytes compared to the control oocytes. Common genes identified in PCOS offspring may be used as potential predictors of PCOS phenotype.

Limitations, reasons for caution: Which factors contribute to the abnormalities of chromatin accessibility in PCOS oocytes are still unknown.

Wider implications of the findings: The candidate genes may be used as potential predictors of PCOS phenotype and provide the clues for PCOS offspring .

O-106 Bringing Transparency to Oocyte Assessment: the importance of including confounders when building Artificial Intelligence (AI) based support tools to quantify oocyte viability

A. Brualla[1], A. Lim[2], A. Zepeda[3], C. Hickman[4]

[1]*Fairtility, Embryology, Barcelona, Spain*
[2]*Alpha Fertility Centre, IVF Lab, Selangor, Malaysia*
[3]*Fairtility, Clinical, Tel Aviv, Israel*
[4]*Fairtility, Clinical, London, United Kingdom*

Study question: Which confounders (sperm quality, oocyte dysmorphism, culture time, images pre or post-ICSI, age) affect the ability of AI to predict blastulation based on oocyte images?

Summary answer: Sperm quality, oocyte dysmorphism, pre or post-ICSI image should be controlled for when building AI algorithms to predict blastulation based on oocyte images.

What is known already: Previous studies reporting on the use of AI to predict blastulation based on oocyte images have: (i) not accounted for confounders affecting blastulation (i.e. sperm quality, culture time), and (ii) used post-ICSI images; without assessing whether the ICSI procedure affects the oocyte image as assessed by AI. Therefore, there is a risk of mislabeling

viable oocytes as non-viable due to external factors, which could cause uncontrolled bias and failure to generalize when used in clinical practice. The objective was to assess how these confounders affect efficacy of prediction of blastulation from oocyte images by an AI-based oocyte assessment tool: CHLOE-OQ(Fairtility).

Study design, size, duration: Cohort study. Images of 1281 oocytes (February to June 2022) were taken pre and post ICSI using the Embryoscope, and the embryos cultured until day 7. Oocyte donor source and age, oocyte dysmorphias and sperm quality were documented. CHLOE-OQ algorithm was trained, validated and tested in a diverse data set, accounting for pre and post ICSI image datasets, quality of oocytes, quality of sperm and patient age.

Participants/materials, setting, methods: The primary endpoint was blastulation. Sperm quality data was classified into 4 groups: (A)All (n = 1281), (B)donor sperm only (n = 51), (C)donor sperm and normospermic samples from men not diagnosed with male factor infertility (n = 557), (D)abnormal sperm samples and other diagnosed male factor cycles (n = 747). Eggs were classified by source (own/donor), and by dysmorphisms: enlarged perivitelline space, abnormal Zona pellucida, cytoplasmic abnormalities, dark, enlarged oocytes.

Main results and the role of chance: Post-ICSI images had higher mean CHLOE-OQ score than pre ICSI images (0.28 ± 0.1 vs 0.33 ± 0.1, $p < 0.001$, paired t-test). Discrepancies were particularly identified in oocytes that degenerated following ICSI, and scored 0 by CHLOE-OQ despite having higher scores pre-ICSI. Using Post-ICSI images (AUC=0.66, 95% confidence interval, CI: 0.63-0.69, n = 1281) improved the efficacy of prediction of blastulation compared to pre-ICSI images (AUC=0.57: 0.53-0.60, n = 1281, $p < 0.001$), suggesting that ICSI affected the quality morphology of the oocyte, and how an oocyte responds to ICSI, as assessed by AI, contributes to prediction of blastulation.

Efficacy of prediction (AUC) was not affected by the quality of the sperm: (A-OVERALL 0.658 [CI(95%): 0.626-0.687]; B-Donor 0.586 [CI(95%): 0.449-0.728]; C-normospermic 0.645 [CI(95%): 0.600-0.688], D male factor 0.678 [CI(95%): 0.639-0.715]).

Oocyte features associated with low CHLOE-OQ scores were: enlarged perivitelline space, dysmorphic oocytes, abnormal Zona pellucida, cytoplasmic abnormalities and dark and enlarged oocytes. Whilst spherical oocytes with normal zona and perivitelline space were characterized as being more likely to form a blastocyst.

Limitations, reasons for caution: This single-clinic study is retrospective. A multi-center study is underway. External factors affecting blastulation must be accounted for to avoid mislabeling of good oocytes as non-viable. There is also a need to understand oocyte dysmorphias identified by the AI algorithm to ensure biological transparency in clinical decision making.

Wider implications of the findings: Taking into account clinical and gamete confounders when building AI algorithms is a necessary strategy to ensure AI algorithms are generalized when incorporated into clinical practice, whilst reducing bias and promoting transparency in clinical decision making. The risk of not considering confounders leads to mislabeling, bias and inaccurate predictions.

Study question: What are the effect and corresponding mechanisms of chromosome chaos of sperm caused by mutation of the MEIKIN gene on preimplantation embryo development?

Summary answer: Sperm chromosome chaos induced by MEIKIN gene mutations directly causes blastocyst formation failure by affecting the activation of the embryonic genome and lineage differentiation.

What is known already: In mice, Meikin is a meiosis-specific kinetochore factor that plays a crucial role in mono-orientation and protection of centromeric cohesion in meiosis I and the regulation of chromosome alignment during meiosis II. Both male and female Meikin gene knockout mice are completely infertile. Infertility in male Meikin$^{-/-}$ mice originates from defects in meiotic chromosome segregation and subsequent spermatogenesis. To our knowledge, no mutation of the MEIKIN gene has been reported in humans.

Study design, size, duration: In this study, semen from three patients with MEIKIN mutations and arrested embryos from one of them were analyzed to determine the effect of MEIKIN mutations on sperm and early embryonic development.

Participants/materials, setting, methods: Three male patients with MEIKIN mutations with a specific clinical phenotype were recruited. We assessed mutant sperm morphology using Papanicolaou staining. Sperm FISH and single sperm chromosome aneuploidy analysis(CNV-seq) were applied to identify mutant sperm Chromosomal abnormality. We also investigated the chromosome constitution and gene expression of the arrested embryos from one patient by parallel single-cell genome and transcriptome sequencing.

Main results and the role of chance: Novel mutations in the MEIKIN gene were identified in three infertility males with a specific clinical phenotype(They had good-quality embryos on day 3, but these embryos repeatedly failed to implant or develop to the blastocyst stage). Routine semen assessments were conducted based on the WHO's guidelines, and all these patients were diagnosed with oligoasthenoteratozoospermia. Sperm FISH showed that the frequencies of aneuploidies in spermatozoa were significantly higher than the normal control(89.05%,70.9%,93.24% vs. 5.03%), and the CNV-seq analysis of single spermatozoa confirmed mutant sperm had severe chromosome chaos. Each cell of the arrested embryos from one patient had complicated chromosomal abnormalities, and the abnormal chromosomes were mainly derived from sperm. At the gene expression level, these embryos were arrested at the 8-cell to morula stage transition, and defects activation of a large ZGA and lineage specification genes led to blastocyst formation failure.

Limitations, reasons for caution: In this study, we discovered that mutations in MEIKIN caused male infertility manifesting as sperm chromosome chaos and blastocyst formation failure. However, the molecular mechanism of the sperm chromosome chaos involved in blastocyst formation needs to be further illuminated by using Meikin knockout mouse models.

Wider implications of the findings: We first reported that male with MEIKIN mutations is related to severe sperm chromosome abnormalities and blastocyst formation failure. Therefore, In the process of ICSI, if there are good-quality cleavage embryos that repeatedly fail to implant or develop to the blastocyst stage, it is recommended to examine male factors concurrently

INVITED SESSION

SESSION 35: THE C-SECTION SCAR DEFECT PANDEMIA

Tuesday 27 June 2023 Hall D3 08:30 - 09:30

Abstract citation ID: dead093.131
O-108 C-section scar defect: Hysteroscopic vs laparoscopic repair

R. Mashiach[1], Y.Z. Burke[2]

[1]Haim Sheba Medical Center Ramat Gan Israel, Gyncology, Ramat Gan, Israel
[2]Haim Sheba Medical Center- Ramat Gan ISRAEL, Gynecological, Ramat Gan, Israel

Objective: To present a systematic review of the literature on the hysteroscopic and laparoscopic repair of cesarean scar niche and offer an evidence-based approach to the treatment of cesarean scar niche.
Data sources: A thorough search of the PubMed/Medline, Embase, and Cochrane databases was performed. (PROSPERO registration number CRD42020190668).
Methods of study selection: Studies from the last 20 years that addressed cesarean scar niche repair were collected. Both authors screened for study eligibility and extracted data. All prospective and retrospective studies of more than ten women were included.
Tabulation and integration: The initial search identified 666 articles [PRISMA flow chart]. We excluded duplicates, case reports, reviews, video articles, and technique articles. We also excluded studies describing only laparotomy or vaginal repair as these were not of the scope of this review.

A total of 31 articles met the inclusion criteria, 21 for hysteroscopic resection and 13 for laparoscopic or combined repair (4 articles tested both modalities and appear in both tables).
Results: For abnormal uterine bleeding (AUB), hysteroscopic remodeling relieved symptoms in 60%-100% of cases and laparoscopy in 78%-94%. Secondary infertility was not evaluated in all studies. We found that after hysteroscopic and laparoscopic treatment, 46%-100% and 37.5%-90% of those who wished to conceive became pregnant following the procedure, respectively.

Pain and dysmenorrhea seem to be uncommon. All studies that tested improvement of pain had less than ten women. However, it would appear that between 66% and 100% of women who complain of pain or dysmenorrhea will note a marked improvement to full resolution.
Conclusion: cesarean scar niche or cesarean scar defect is usually asymptomatic. For symptomatic women, a repair is a valid option. For those with RMT (Residual Myometrial thickness) >2-3 mm, hysteroscopic remodeling is the modality of choice with an improvement in AUB, secondary infertility, and pain. For women with a RMT <2-3 mm, laparoscopic repair with simultaneous hysteroscopic guidance shows similar results. Since available data is limited, no cutoff for the correct choice between hysteroscopy or laparoscopy can be concluded. We recommend 2.5 mm as the cutoff value based on common practice and expert opinion, although no significance between hysteroscopic and laparoscopic treatment was shown.

O-109 Avoiding the C-section scar defect

Z. Kalem[1], M. Namli Kalem[2]

[1]Istinye University School of Medicine, Dept. of Ob/Gyn, ISTANBUL, Turkey
[2]Istinye University, Obstetrics and Gynecology, Istanbul, Turkey

The cesarean scar defect was first described in 1961 by Poidevin et al. Cesarean delivery is one of the most common surgeries today, and millions of women give birth this way every year. The prevalence of cesarean scar defect is increasing due to increasing cesarean section rates. The cesarean scar defect is called by different names in the literatüre, such as isthmocele, niche, diverticulum, dehiscence of the cesarean scar. It was discovered that the prevalence of isthmocele varied widely. Using contrast-enhanced sonohysterography, the prevalence in a random group of women with a history of CS was between 56% and 84%, whereas the incidence in pelvic ultrasonography fluctuates between 6% and 36%.

The most common gynecological problems that may occur due to isthmocele are menstrual spotting, dysmenorrhea, dyspareunia, chronic pelvic pain, and infertility. The likelihood of scar pregnancy, placentation abnormalities, and uterine rupture increases with subsequent pregnancies. Both hysteroscopic and laparoscopic isthmocele repair techniques are highly effective. Therefore, precautions against isthmocele during cesarean delivery should be made more transparent.

The development of isthmocele is influenced by the timing of the cesarean section (during pre/early or advanced labor), the position of the uterine incision (its distance or proximity to the internal os of the cervix), and the opening and closing (suturation) method of the uterine incision. Once more, both gestational diabetes and being overweight might be viewed as independent risk factors.

Understanding the risk factors for isthmocele development will aid in the development of preventative measures. The two most crucial elements in the formation of isthmocele, according to our knowledge of the literature, are the site of the uterine incision and the suture methods. In this presentation, we will discuss ways to prevent the development of isthmocele.

INVITED SESSION

SESSION 36: DEBATE: MILD VERSUS CONVENTIONAL STIMULATION IN ART

Tuesday 27 June 2023 Hall D1 08:30 - 09:30

Abstract citation ID: dead093.133
O-110 Mild stimulation is the future in ART

G. Nargund[1]

[1]Create Fertility, Medical Director, London, United Kingdom

The World Health Organisation has called for a simple, safe, and effective IVF treatment which could be both affordable and widely accessible. Unfortunately, IVF practice in developed countries seems to be trending in the opposite direction, making ovarian stimulation more intense, complex, expensive, and globally inaccessible, under the pretext of maximising the cumulative live birth rate (LBR) or by offering a 'package' of a 'complete family' from a single attempt of IVF.

In reality, data from randomised controlled trials (RCTs) has found no difference in fresh cycle as well as cumulative LBRs whether a mild or high stimulation dose is administered. This is because, higher oocyte yield with high ovarian stimulation does not translate into better-quality embryos and this has been demonstrated in systematic reviews and meta-analyses.

There appears to be confusion between stimulation 'dose' and 'response'. Young women with good ovarian reserve are more likely to have a high response to stimulation despite being treated with a dose that falls within the definition of 'mild stimulation', whereas aggressive stimulation fails to improve the response in poor responders. A rising cumulative LBR with increasing number of oocytes is attributable to these good responders, but this is disconnected with the intensity of ovarian stimulation.

The euploid embryo yield similarly is related to the number of oocytes and cumulative LBR which are influenced by the woman's age and ovarian reserve but not the stimulation dose. Both the numbers of aneuploid and euploid embryos rise with increasing oocyte yield, keeping the proportion unchanged.

Advocates of 'one and done' approach have shown that only 1 in 5 women can produce the requisite number of oocytes to have more than 1 child. This means, the remaining 80% patients would be subjected to intense stimulation, incurring risks of overstimulation, treatment burden and cost without achieving the goal of 'completing' their family. Psychological analysis from a RCT reported a higher incidence of post-treatment depression after Conventional compared to Mild IVF. Even in the era of agonist trigger and 'freeze all

embryos', OHSS has not been totally eliminated- the World Registry reported around 40 cases of severe OHSS in 10 000 cycles. Clinical complications such as haemorrhage and infection associated with overstimulation could be magnified in low-resource settings with lack of facilities and expertise.

Livebirth rates albeit of key importance cannot be the only index of success. Our commitment should be to make IVF accessible globally by adopting effective stimulation protocols that reduce treatment burden and cost for the patient and improve health outcomes for mother and baby. Only mild stimulation IVF can fulfil this global vision and need as an increasing body of evidence has confirmed that mild stimulation is as successful as conventional stimulation, while being safer and less expensive. Individualised mild stimulation protocols are the smartest way forward in a global setting for all patient groups. It is time to reflect on what is best for our patients and society in the long-term.

Abstract citation ID: dead093.134
O-111 Conventional stimulation remains the gold standard

E. Bosch Aparicio[1]

[1]*Instituto Valenciano de Infertilidad, Human Reproduction, Valencia, Spain*

Ovarian stimulation (OS) remains a crucial step of IVF process since cycle outcomes per cycle after OS are remarkably higher when compared to a natural or modified natural cycle. Within the concept of OS, two approaches are purposed: On one hand, "mild" stimulation claims for the use of low doses of gonadotrophins in order to yield a moderate number of eggs that should be enough to achieve a pregnancy. On the other, the so called "conventional" stimulation aims to maximize ovarian response, with the goal of obtaining the higher number of embryos that is possible and therefore increase the number of attempts per pick up to reach the highest chance of pregnancy for each patient in one cycle.

Defenders of mild stimulation, claim that obtaining oocytes beyond a certain response (classically eight eggs) is useless, since these surplus oocytes won't be able to provide good quality embryos. In other words, this statement is based in a hypothesis according to which a soft stimulation of the ovaries would lead them to mature only the good quality eggs, while those of lower quality would not respond to these low doses and would remain immature in the ovaries. A few numbers of old studies performed with outdated technologies support this this concept.

However, a large body of evidence shows that the contrary is true. Old studies that related ovarian response to cycle outcome considering only the chances of achieving a live birth after just a fresh embryo transfer, showed that live birth rate increased as the ovarian response did up to around 15 oocytes, while it shows a "plateau" beyond this response. But moreover, more recent studies in which the cumulative live birth rate achieved after one live birth is achieved or until all viable embryos that were cryopreserved were transferred, shows that it improves linearly as the ovarian response does, starting to plateau only for ovarian responses larger than 35-40 eggs.

A very recent study that analyses more than 400,000 cycles from the Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART) confirms these figures. This large sample allows for stratified analysis according to age, BMI, AMH or infertility diagnoses that further confirm the findings. Altogether, these studies show that the concept of some kind of "oocyte quality selection" happens when a mild stimulation is used does not really happen. Large ovarian responses increase the number of good and bad quality oocytes equally.

The idea of ovarian stimulation hampering oocyte quality has been around for more than 30 years. Theorical concepts based on observations in the animal model suggested that this might be the case. However, studies in humans have been unable to prove this hypothesis. In this context, the best model to prove this concept is the intra-patient comparison between the non-stimulated and the conventionally stimulated cycle. Our group has performed two studies following this approach so far. In the first one, we included 46 oocyte donors. PGT-A was performed to the embryos obtained in both cycles, which at time was performed on day 3 embryos with FISH technology. The study showed that there were no significant differences in the aneuploidy rate between the 2 cohorts of embryos (34.8% vs 32.8%), suggesting no harm of ovarian stimulation. These findings have been recently confirmed in 40 infertile patients aged 30-38, in which PGT-A was done with a comprehensive chromosomal analysis using NGS after blastocyst biopsy.

In conclusion, research and clinical evidence show that conventional OS does not harm oocyte quality and increases the cumulative birth rate per oocyte pick-up, making it as the first choice for treating patients with IVF.

SESSION 37: FROM PIONEER TO PRESENT PRACTICE OF FERTILITY CARE PROVIDERS

Tuesday 27 June 2023 Hall D4 08:30 - 09:30

Abstract citation ID: dead093.135
O-112 Jean Purdy - The silent partner

H.J. Kendrew[1]

[1]*None, None, Bradford-on-Avon, United Kingdom*

The development of a novel technique requires a diverse team whose individuals share the same goal but who each bring a different strength and aspect of their personality to the research/ project.

A "front man" with tenacity drive and vision needs the support of such team. To quote Aristotle "The whole is greater than the sum of it's parts".

This expression could be aptly applied to the pioneers of IVF, Robert Edwards and Patrick Steptoe about whom much has been written. Their drive and determination in the face of societal opposition and competition from across the Atlantic, was supported by a silent group of lesser known individuals.

Jean Purdy (research nurse and laboratory assistant), Muriel Harris (operating theatre superintendent), Lillian Lincoln Howell (philanthropist) and Ruth Fowler (scientist and Robert Edwards wife). Not to mention the 280 unidentified women patients and their partners who played their part. All drawn together in the quest to try and help patients achieve the families they so desired.

In my presentation I am concentrating specifically on the life Jean Purdy and her contribution to the work which sees us all here today in Copenhagen.She had a short but pivotal life, often attributed to being the first embryologist, prematurely dying at the age of 39 from malignant melanoma.

As of March 2021 at least eight million babies worldwide have been born from IVF. I wonder how astounded these pioneers would be to see how far we have come and what they would make of the world wide impact they made in the face of significant criticism, moral outrage and scepticism from their professional peers, the church, media and society?

Abstract citation ID: dead093.136
O-113 Recent research on fertility staff emotions

F. Fedele[1]

[1]*Italian Assisted Reproductive Technologies Register, Italian National Institute of Health, Rome, Italy*

Infertility-related psychological research is traditionally oriented more at analysing the wellbeing of couples undergoing Assisted Reproductive Technologies (ART), than to studying the job-related effects on the healthcare fertility staff.

The unfulfilled desire for a child can cause an emotional crisis for couples: they may experience high levels of stress with physical, emotional, social and financial concerns related to infertility and ART treatment.

Little is known instead about the emotional reaction of healthcare members to infertility and treatment delivery. In fact, it is well documented that patients with infertility problems may challenge usual approaches to care,

leading to potential difficulties in the therapeutic relationship: patients undergoing ART are often dissatisfied with the level of empathy and attention received by the healthcare staff. Besides, patients may be experienced as manipulative, emotionally dependent, self-destructive, non-compliant and with a hostile attitude, thus raising negative feelings of frustration, anxiety, and dislike among healthcare professionals.

This is the aim of the research titled "What about fertility staff emotions? An explorative analysis of healthcare professionals' subjective perspective", aimed at understanding the subjective perspective of the fertility professionals and their emotional dynamics in relationship with patients. An in-depth explorative research study was conducted on 12 healthcare professionals working in the fertility clinic of a public healthcare hospital of Rome. Structured interviews with open-ended questions were conducted and Emotional Text Analysis was carried out to analyse the transcripts of their interviews. Five thematic domains were detected that describe the staff's emotions about their professional experience, as follows: performance anxiety (Cluster 1), ambivalence between omnipotence and powerlessness (Cluster 2), care burden (Cluster 3), feeling of duty (Cluster 4), and sense of interdependence (Cluster 5). This study suggests that the professionals' awareness about the implicitly emotional meanings, beliefs, values, referred to the professional function and therapeutic relationship may facilitate team work and care relationship.

For this reason, the Italian National ART Register of the National Institute of Health and the Department of Dynamic Clinical and Health Psychology of La Sapienza University carried out a research to examine the characteristics of psychological services in Italian ART centres. A questionnaire consisting in 26 questions was sent to the physicians in charge of 341 ART centres active in Italy.

The overall picture was rather disappointing in that only half of the responding centres (47%) have a psychologist permanently on staff and psychological intervention seems to be considered as targeting the inner world of the individual or the couple and not their relationship with the ART context. Moreover, relatively few couples (10-20%) resort to counselling in 70% of the responding centres. Referrals did not seem to be regulated by specific policies and procedures in 60% of the cases and in 70% of centres the fee for psychological counselling was not included in the ART treatment fee. Furthermore, 30% of the responding centres worked with an independent psychologist who is called in upon request.

It is possible to hypothesise instead that health professionals in the field of reproductive medicine could offer their care on an ongoing basis during the course of treatment with an integrated and collaborative approach that also involves:

1. education, training, and support of the fertility clinic staff to help reduce staff stress, prevent burnout, and improve overall patient care.

2. offer support to adopt an emotional accompanying function into the healthcare relationship, through attempts at restitution, clinical supervision, joint listening setting (physician, psychologist, patients), analysis and sharing of the emotional dimensions involved in the Centre's activity, in order to improve the care experience of the patient and of the carers in relation to each other.

This approach may represent a real multidisciplinary model of caretaking.

INVITED SESSION

SESSION 38: FERTILITY PRESERVATION OR GAMETE DONATION FOR CHILDHOOD AND YOUNG ADOLESCENTS WITH HEREDITARY CANCER?

Abstract citation ID: dead093.137

O-114 Fertility preservation in males with hereditary cancer syndromes: balancing the risks and benefits

R. Mitchell[1]

[1]*University of Edinburgh, MRC Centre for Reproductive Health Edinburgh, United Kingdom*

Abstract citation ID: dead093.138

O-115 Fertility preservation or egg donation for hereditary cancer syndromes?

F. Filippi[1]

[1]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico, Infertility Unit, Milan, Italy*

Individuals with hereditary cancer syndromes are at risk of developing multiple tumours and, therefore, undergo life-long surveillance procedures and risk-reducing and/or therapeutic surgeries. Knowledge and testing for hereditary cancer susceptibility genes is rapidly spreading, often performed at the first cancer diagnosis.

Different physical, psychosocial, ethical and economic considerations need to be taken into account when deciding on reproductive options in individuals with a hereditary cancer syndrome.

The psychosocial impact of genetic predisposition to cancer may be particularly problematic and still represents an ongoing challenge for the professional taking care of these patients. In fact, worries about passing on a genetic risk for cancer to offspring are concerns expressed by the 65% of female young adult cancer survivors when specifically interviewed.

At cancer diagnosis, fertility preservation procedures represent an effort to retain the opportunity to have genetically related children. Unfortunately, oocytes, embryo or ovarian cortex cryopreservation do not guarantee live birth. The success rates of these procedures are highly dependent on age, number of oocytes cryopreserved and may be influenced by other medical, lifestyle and (future) male factors. In addition, carriers of pathogenetic gene variants for cancer predisposition should also be thoroughly counselled about preimplantation genetic testing (PGT), a technique allowing the interruption of passing on the gene associated to cancer risk. However, this option inevitably lowers the efficacy of fertility preservation interventions in terms of future pregnancies.

Egg donation is a spreading procedure with higher success rates than fertility preservation techniques. This approach allows individuals to avoid undergoing oocytes retrieval or ovarian tissue cryopreservation surgery, thus avoiding procedural risks (infection, haemorrhage, ovarian hyperstimulation syndrome) and postponement of oncological treatments. On the other side, offspring will not have a genetic link with recipient and the beneficial psychological role of fertility preservation would be missing. In fact, several recent studies have underlined the message of hope that is indirectly perceived by oncological patients when counselled for fertility preservation. Moreover, counselling on the possibility of egg donation is challenging at the time of cancer diagnosis.

Making the right reproductive choice in carriers of hereditary cancer syndromes is a dilemma which can't be solved generalizing. Even patients' attitude could be different according to the time of counselling, whether is at cancer diagnosis or at the genetic predisposition diagnosis in healthy carriers. Egg donation should be considered in the available armamentarium. The complexity of the topic needs a personalized and multidisciplinary counselling.

INVITED SESSION

SESSION 39: RAISING FERTILITY AWARENESS FOR EVERYONE

Tuesday 27 June 2023 Hall D5 08:30 - 09:30

Abstract citation ID: dead093.139

O-116 Benefits

L. Schmidt[1]

[1]*University of Copenhagen, Department of Public Health, Copenhagen K, Denmark*

The World Health Organization's Sustainable Development Goal 3.7 covers sexual and reproductive health to ensure universal access to sexual and reproductive health care services, including family planning, information & education and the integration of reproductive health into national strategies.

Globally, infertility is one of the most frequent chronic diseases among men and women of reproductive age. Infertility is associated with a number of different risk factors from medical diseases some being congenital; various infections like tuberculosis, sexually transmitted infections like chlamydia; health-behaviour like smoking, obesity, use of cannabis, advanced age; unsafe abortions; insufficient access to good quality pregnancy care and delivery care; and reproductive risk factors at workplaces and in the environment. In many cases infertility is preventable by reducing risk factors. In order to prevent infertility, national strategies are needed on an individual and societal level.

One of the important strategies is to raise fertility awareness for everyone – this includes increased fertility awareness for young adults, their parents, health care staff, teachers and others who are in contact with young adults, but also politicians and stakeholders who have a huge impact on how to organize our societies including sufficient access to safe reproductive care to support people to have the children they desire (or to stay childfree if they prefer).

On a global level, surveys and interview studies have repeatedly shown that a high proportion of people have insufficient knowledge regarding fertility and risk factors for infertility, and they falsely believe that medically assisted reproduction is nearly always successful. The studies also show that many people are aware of their limited knowledge. Recent studies find that young adults express a need for being better educated in this field and many prefer a course in sexual education including fertility knowledge when they are undergoing their youth education. Study participants prefer to have fertility knowledge in advance in order better to take care of their fertility potential when they desire to have children.

It is also of importance to increase fertility awareness among parents, as a proportion of young adults talk to their parents about when to have children. Parents especially in high-income countries could encourage their children to postpone family building to ages where it could be difficult for their sons and daughters to have sufficient time to have the number of children they desire. Other studies show that also health care professionals like doctors and nurses outside of the fertility field have limited fertility knowledge and hence could give their patients poor advice when it comes to reducing infertility risk factors and when to seek medically assisted reproduction.

There are several benefits of globally raising fertility awareness for everyone: 1) to ensure that people are able to make well-informed decision-making regarding their own family building. 2) To prevent infertility and reduce the proportion of people in need of medically assisted reproduction. 3) To be able to organize societies to become family friendly. 4) To support NGOs and others to fight for universal access to safe sexual and reproductive health care including access to contraception, safe abortions and safe pregnancy and delivery care. 5) To secure sufficient access to high-quality medically assisted reproduction for those in need of treatment to become parents. 6) To stop using harmful substances that impact fertility at workplaces and in the environment.

Abstract citation ID: dead093.140
O-117 Challenges

M. Simopoulou[1]

[1]*National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece*

Fertility awareness is heavily charged "meaning" different things to different people, from how to avoid pregnancy, to how to have children, but this should not be the only focus. Fertility awareness should employ the life course approach to improve reproductive health and facilitate decision-making in family planning among adolescents, people of reproductive age, primary healthcare, education professionals, and policymakers through development, evaluation, and dissemination of inclusive educational resources. Fertility and reproductive health education are distinct but intertwined. As raising awareness on fertility means that reproductive health should be covered, the International Fertility Education Initiative (IFEI) recently changed our name to the International Reproductive Health Education Collaboration (IRHEC). The work that IRHEC has done with schools, highlights that covering the life course of reproductive health is important for all, irrespective of attitudes.

Finding the right language to communicate harbors risks on unintended negative effects such as dissonance and anxiety. The IRHEC's recent publication focuses on 5 recommendations: 1) to frame fertility awareness messages with (reproductive) autonomy in mind aiming for inclusion of those who do not represent the traditional nuclear family; 2) ensure fertility health messages are empathetic and steer clear of blame; 3) avoid scaremongering and offer a positive angle; 4) address both women and men in fertility health messaging; and 5) tailor messages to particular contexts and audiences and develop resources in close collaboration with the target groups.

The measurable impact of all educational resources should be evaluated. This is challenging owing to lack of standardized education and of specific benchmark for satisfactory knowledge gain, along with the challenge of developing evaluation standards. The IRHEC has identified the need to systematize recommendations and describe the best evidence on effectiveness.

Examining evidence of knowledge, attitudes and behavior in different countries to identify knowledge gaps is key. Research indicates that key ways to educate is in schools, using digital technology, social media and health professionals. For schools, curriculum vary in different countries from teaching nothing, to teaching how to prevent a pregnancy. Reproductive health education in schools will ensure that young adults will be well-equipped towards informed decision-making. The IRHEC has been working towards understanding how to best teach reproductive health, with work done in the UK, and repeated in Belgium and Greece. A teacher's guide in a "train-the-trainers" mentality has been produced to help teachers deliver reproductive health education. The challenge of an effective multidisciplinary collaboration between policymakers and educators is well acknowledged.

Research on education employing social media is valuable to establish who is influencing reproductive health education, what is their impact, what information they are posting, and how effective it is. Data can help to indicate how to best use social media to deliver fertility education.

A "one-size-fits-all" philosophy for reproductive health education is out of the question. Studies have indicated that target audience may perceive the education as guided and feel obligated to comply with societal pressures. This, in turn, may generate misconceptions and backlash resulting in questioning, suspicion and skepticism. Cultural, religious and socioeconomical factors complicate further, as does the role of social media in perpetuating misconceptions. The problem posed by lack of tailored information is showcased considering the paradigm of addressing the LGBTQ+ community, as there is limited data in literature, while the community may be rendered vulnerable because of marginalization, and normative pressure.

To address challenges, multidisciplinary should evolve to interdisciplinary. The future should hold recommendations and guidelines. Data highlights the significance of establishing government-sponsored fertility education programs, across all countries and for all ages, however Governments' approval pauses a conundrum. The way forward features personalized education, whilst aiming for high-quality robust evidence.

[3]SA Pathology, Padiatrics, Adelaide, Australia
[4]Robinson Research Institute, Lifecourse and Intergenerational Health, Adelaide, Australia
[5]University of Adelaide, Public Health, Adelaide, Australia
[6]The Robinson Research Institute, Lifecourse and Intergenerational Health, Adelaide, Australia

Study question: Is the risk of urogenital defects increased in live births where clomiphene citrate is known to have been dispensed by a pharmacist to the individual?

Summary answer: The risk of urogenital defects is elevated in singletons, and approximately doubled in male babies among women dispensed clomiphene citrate, as compared to unexposed women.

What is known already: Clomiphene citrate (CC) has been used for ovulation induction since 1967 & is both inexpensive and largely effective. However, CC is a selective estrogen receptor modulator (SERM), which is a class of drugs with the potential for endocrine disruption during fetal development. The link between urogenital defects and CC has previously been reported by ourselves and others.

Whether the link continues to exist where individual level pharmaceutical prescribing and dispensing patterns are clearly ascertained has not been determined.

Secondly, the interaction of prescribed clomiphene citrate functioning as an endocrine disruptor by fetal sex has not undergone formal statistical testing.

Study design, size, duration: A population-based cohort study of South Australia was assembled by linking all records from the state-wide perinatal registry for births between July 2003 and December 2011, including defects coded to ICD9 and BPA, with Commonwealth government data on pharmaceutical dispensing in the national Pharmaceutical Benefits Scheme (PBS), which includes individual level prescribing and dispensing of drugs for ovulation induction, including clomiphene citrate.

Participants/materials, setting, methods: We analysed de-identified pregnancy outcome data for all births in South Australia, linked to individual level national prescription data, to examine the prevalence of urogenital birth defects (>20 weeks gestation) for births occurring between July 2003 and December 2011following clomiphene citrate dispensing, with 5-years follow-up for defect notifications. Multivariate analysis in STATA within a Secure Unified Research Environment (SURE) was used to calculate odds ratios, adjusted for maternal confounders and socioeconomic circumstance.

Main results and the role of chance: We examined 2,264 singleton live births where women were dispensed clomiphene citrate for infertility. Births among women dispensed clomiphene citrate, compared to those without this exposure, had increased urogenital defects (odds ratio (OR) = **1.73, CI = 1.34 - 2.24).**

This association was slightly reduced after adjustment for maternal characteristics that were potential confounders: age, socio-economic status (based on postcode of residence), Aboriginal ethnicity, born outside Australia in low or middle income country, parity, smoking, pre-existing diabetes or hypertension, pregnancy-induced hypertension and pre-eclampsia (OR = **1.66, CI = 1.28 -, 2.15)**.

There was evidence of an interaction with fetal sex, such that males were at particular risk.

Sex-by-clomiphene interaction	
Male	**1.92 (1.47, 2.52)**
Female	0.88 (0.37, 2.14)
Test for interaction	$\chi^2(1) = 2.72$; $p = 0.09$

The observed main effects are unlikely to be due to chance, and the sex-specific effect is biologically plausible, but limited in power. Further, there were 280 babies from multiple pregnancies to women exposed to clomiphene citrate that were excluded due to statistical limitations.

Limitations, reasons for caution: Our data report pharmacy dispensing, but not observed consumption, although infertile women are highly motivated to take this drug and over 5% of pregnancies were multiples, consistent with extensive use. The analysis for interactions and for multiples is currently restricted by power, which may resolve as the cohort number increases.

Wider implications of the findings: Clomiphene citrate (CC) may be a potent endocrine disruptor inducing urogenital defects, particularly in males. This is important as CC continues to be a WHO essential drug and a first line treatment globally, but with largely unmonitored use and without any industry initiated prospective safety study.

Trial registration number: Not applicable

P-781 Assisted reproductive technology-associated risk factors for retained placenta

S.C. Jwa[1], S. Tamaru[1], M. Takamura[1], A. Namba[1], T. Kajihara[1], O. Ishihara[1], Y. Kamei[1]

[1]Saitama Medical University, Department of Obstetrics and Gynecology, Saitama, Japan

Study question: What are the assisted reproductive technology-associated risk factors for retained products of conception (RPOC) following delivery?

Summary answer: Frozen embryo transfer (FET) with hormone replacement cycles (HRC) constitutes the largest risk factor for RPOC.

What is known already: RPOC is a key cause of secondary postpartum hemorrhage. Previous studies have shown that the use of ART increases the risk of RPOC and subsequent transfusion following delivery. However, the relationships between specific ART-treatment factors and the risk of RPOC have not been elucidated.

Study design, size, duration: We performed a registry-based retrospective cohort study using the Japanese national ART registry, in which all the ART cycles performed in Japan are recorded including the perinatal outcomes.

Participants/materials, setting, methods: Singleton live births between 2007 and 2017 were studied (n = 306,411). Odds ratios (ORs) and 95% confidence intervals (CIs) for the potential risk factors for RPOC associated with fresh and frozen cycles were obtained from multiple logistic regression analysis, incorporating adjustment for maternal age, infertility, and calendar year. Because information regarding assisted hatching (AH) and HRC for endometrial preparation only became available in 2012, these factors were analysed using the data collected between 2012 and 2017.

Main results and the role of chance: RPOC was diagnosed for 132 deliveries (0.04%), of which 122 (92.4%) followed FET cycles and only 10 (0.01%) followed fresh embryo transfer (ET). No significant risk factors for RPOC were identified using the fresh ET data. For FET cycles, the use of HRC as an endometrial preparation method represented the largest risk factor (adjusted OR, 4.9; 95% CI, 2.0 to 12.3), with RPOC occurring in 0.05% of deliveries following HRC (51/97, 958 deliveries) but in only 0.01% following natural cycles (5/47, 79 deliveries). AH was also associated with a significantly higher risk of RPOC (adjusted OR, 1.9; 95% CI, 1.2 to 3.1), although the risk was lower than that associated with HRC). Subgroup analysis showed that these significant associations of HRC and AH with RPOC were present for transvaginal deliveries, but not deliveries by caesarean section.

Limitations, reasons for caution: The registry lacks important information regarding risk factors for RPOC, such as parity, body mass index, and history of previous uterine surgery. Furthermore, the lower prevalence of RPOC in the present study (0.04%) than in other studies (approximately 1%) suggests the possibility of non-differential misclassification for the outcomes of RPOC.

Wider implications of the findings: Although the possibility of residual confounding factors remains, the present findings suggest that additional care should be taken in the management of patients undergoing vaginal deliveries following FET who have HRC or AH.

P-782 The influence of microfluidic preparation of spermatozoa for ICSI (intracytoplasmic sperm injection) in an unselected IVF population on fertilization rate, embryo-quality and pregnancy rate

C.A. Huniadi[1], I. Zaha[2], S. Liana[2], N. Petronela[3], S. Andrea[2], R. Ioana[4], B. Cosmina[3], R. Miheala[3]

[1]*CALLA IVF, OBSTETRICS GYNECOLOGY, ORADEA, Romania*
[2]*Calla IVF, Obstetrics-gynecology, Oradea, Romania*
[3]*Calla IVF, Embryology, Oradea, Romania*
[4]*National Transplant Agency, National Transplant Agency, Bucharest, Romania*

Study question: Does the microfluidic technique as a new preparation option for sperm in ICSI during IVF have a better outcome in fertilization, blastocysts and pregnancy rate?

Summary answer: The patients that had the sperm preparation for ICSI with the microfluidic sperm selection had similar results as with the gradient centrifugation selection.

What is known already: Semen analysis is a poor predictor of the fertilization potential of spermatozoa and a male factor may contribute to poor outcomes of IVF procedure despite a normal semen analysis. Traditionally, sperm processing is accomplished by density gradient centrifugation or swim-up methods but this have been shown in some studies to increase reactive oxygen species and induce sperm DNA fragmentation. The microfluidic sperm selection (ZyMot- ICSI) is based on the selection of the spermatozoa with the lowest DNA fragmentation rate but studies do not prove better clinical outcomes after this method.

Study design, size, duration: This is a prospective randomized study carried out in a university level fertility clinic in Oradea, Romania from January 2022 to December 2022, including 239 patients in total. The patients that underwent IVF-ICSI procedures for various indications were randomized in two groups: the control group swim-up technique was used for sperm selection for ICSI during IVF and the study group with the ZyMot-ICSI (microfluidic sperm selection technique) was used.

Participants/materials, setting, methods: We conducted a prospective trial comparing 119 couples that were allocated to the classic swim-up technique (control group) and 120 couples that were allocated with the microfluidic technique was used (study group) in our university level clinic to go through IVF. Inclusion criteria were couples with known infertility requiring IVF and willing to participate in the study. Exclusion criteria were: severe oligoasthenospermia (concentration $<$ 5x106 spermatozoa/ml or motility $<$10%), oocyte or sperm donation.

Main results and the role of chance: The statistical analysis showed that there is no significant difference between the fertilization rate (study vs control $p = 0.37$ with absolute difference -1.182, 95% CI (-7.2, 5.4)) or blastocyst rate (study vs control $p = 0.88$ with absolute difference -0.5 95% (-6.5, 6)) nor is there a difference in clinical pregnancy. Even if microfluidic preparation of spermatozoa did not seem to improve the results it may be utilized more broadly for standard IVF, intrauterine insemination and could also improve workflow, decrease intervention by laboratory personal and provide more consistent incubation conditions.

Limitations, reasons for caution: The population studied was inclusive with unselected IVF indications and did not attempt to isolate male factor infertility cases or patients with a history of elevated sperm DNA fragmentation.

Wider implications of the findings: Microfluidic sperm preparation performs similarly to density gradient centrifugation in sperm preparation for IVF in an unselected population.

P-789 Unexplained subfertility in women aged 38 years and above: could intrauterine insemination be an alternative for in vitro fertilization? A systematic review and meta-analysis

J. Rake[1], M. Mochtar[1], E. Van Putten[1], M. Van Wely[2]

[1]*Amsterdam UMC, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Amsterdam UMC, Center for Reproductive Medicine, Center for Reproductive Medicine, The Netherlands*

Study question: Considering current available evidence, how do intrauterine insemination and IVF compare in terms of pregnancy outcomes in women aged $>$ 38 years with unexplained subfertility?

Summary answer: In women $>$ 38 years both IUI and IVF lead to pregnancies and live births, there is insufficient evidence to determine the relative effectiveness

What is known already: Solid evidence has shown that intrauterine insemination (IUI) with ovarian stimulation (OS) is the preferred treatment option for women with unexplained subfertility below the age of 38. In women who are 38 or older IVF is the first choice of treatment, according to the Dutch guideline in order to "not waste any more time" Evidence of IVF being more effective compared to IUI-OS is lacking while IVF compared to IUI-OS is an invasive, costly and burdensome procedure.

Study design, size, duration: We have conducted a systematic review and meta-analysis after a comprehensive literature search which includes articles on IVF, IUI, and both, from May 1985 to May 2022. We have included randomized controlled trials and cohort studies regarding IUI and/or IVF treatment in women aged 38 and above with unexplained subfertility and/or mild subfertility factors.

Participants/materials, setting, methods: The primary outcome was live birth rate and primary safety outcome was miscarriage rate. Data of the comparative IUI versus IVF studies were pooled in a forest plot and expressed in risk ratio with a 95% CI using a random effect model. We calculated prevalence estimates and performed meta-regression to study the effect of age on live birth and miscarriage

Main results and the role of chance: We included 17 studies in our meta-analysis. One RCT compared two IUI cycles with two IVF cycles and found a halving of live birth (RR 0.46, 95% CI 0.25-0.86. $n = 154$), very low-quality evidence especially in view of the unfair comparison in treatment time. Pooling the data of five cohort studies that compared IU with IVF resulted in a comparable risk estimate, though the difference between IUI and IVF was not significantly different (RR 0.56, 95% CI 0.30-1.05, $I^2 = 73\%$, $n = 7288$), low quality evidence in view of the unequal distribution of female age over the groups and the heterogeneity.

Meta-regression on data from IUI studies suggested that IUI above 43 years old resulted in pregnancy chances below 5% (3 studies $n = 397$, only women older than 40). Meta-regression on data from IVF studies (8 studies, $n = 22\,708$) suggested that following IVF, live birth rates declined from about 20% at 38 years to 5% at 43 year and zero above 44 years. At the same time miscarriage rates increased from an estimate of 25% at 38 years old to more than 50% above a female age of 43 years.

Limitations, reasons for caution: Female age, a likely effect modifier, was not equally distributed in the cohort studies, especially in the small IUI cohort studies. The available evidence lacked information on duration of treatment. For a fair comparison the treatment time horizon should be equal.

Wider implications of the findings: It is expected that the average age of women trying to conceive will only further increase within the coming years. Findings of this systematic review underline the importance of a randomized controlled trial to provide more evidence on which treatment should be recommended for women $>$ 38 with unexplained subfertility.

O-118 Morphokinetic embryo behavior in low-prognosis patients according to the POSEIDON criteria: an analysis of 3326 injected oocytes

A. Setti[1,2], D. Braga[1,2], R. Provenza[3], P. Guilherme[3], A. Iaconelli Junior[2,4], E. Borges Junior[2,4]

[1]*Fertility Medical Group, Scientific department, Sao Paulo, Brazil*
[2]*Sapientiae Institute, Scientific research, Sao Paulo, Brazil*
[3]*Fertility Medical Group, IVF lab, Sao Paulo, Brazil*
[4]*Fertility Medical Group, Clinical department, Sao Paulo, Brazil*

Study question: Do embryo quality and morphokinetic behavior differ in the four groups of low-prognosis women as stratified by the POSEIDON criteria?

Summary answer: Embryo quality and morphokinetic behavior differ across the POSEIDON groups, being more favorable in POSEIDON group 1, as well as were implantation and miscarriage rates.

What is known already: Poor ovarian responders (POR) represent 9-24% of patients undergoing ovarian stimulation, and the clinical management of these patients remains a challenge in everyday practice. In an attempt to standardize the diagnosis of POR, the medical community developed the Bologna Criteria and then shifted to the Patient-Oriented Strategies Encompassing IndividualizeD Oocyte Number (POSEIDON). Embryo monitoring with time-lapse imaging (TLI) may allow the identification of morphokinetic events potentially affected by ovarian response. The aim of this study was to compare embryo quality, and speed and pattern of cell divisions in the four groups of POR as stratified by the POSEIDON criteria.

Study design, size, duration: This cohort study included low-prognosis patients undergoing their first intracytoplasmic sperm injection (ICSI) from Mar/2019 to Apr/2022 at a private-university affiliated IVF center, who met the POSEIDON criteria. A total of 3326 injected oocytes from 846 women were analyzed. Kinetic markers from the point of insemination were recorded. Generalized mixed models followed by Bonferroni post hoc were used to compare morphokinetics among the POSEIDON groups. The post hoc achieved power was > 80%.

Participants/materials, setting, methods: Injected oocytes were cultured in the EmbryoScope$^+$ incubator, which recorded the following kinetic markers: timing to pronuclei appearance and fading (tPNa and tPNf), two (t2), three (t3), four (t4), five (t5), six (t6), seven (t7), and eight cells (t8), morulae (tM), start of blastulation (tSB) and blastulation (tB). Durations of second and third cell cycles (cc2 and cc3) and timing to complete synchronous divisions s1, s2, and s3 were calculated. The KIDScore ranking was recorded.

Main results and the role of chance: The results from the generalized mixed models followed by Bonferroni post hoc for the comparison of means among groups showed that embryos derived from patients in the POSEIDON groups 2, 3 and 4 showed significantly slower divisions compared to those from POSEIDON 1 group (Table 1). The KIDScore rank was significantly lower for embryos derived from POSEIDON groups 2, 3 and 4 (2: 4.4 ± 0.7 vs. 3: 4.2 ± 0.2 vs. 4: 3.0 ± 0.4) compared to those derived from POSEIDON 1 group (4.8 ± 0.1, $p < 0.001$). Group POSEIDON 1 also showed improved implantation (26.9% vs. 2: 22.4% vs. 3: 20.0% vs. 4: 14.0, $p < 0.001$) and miscarriage rates (5.6% vs. 2: 31.2% vs. 4: 50.0%, $p = 0.013$).

Limitations, reasons for caution: The use of historical cohort groups is a drawback. Despite the eligibility criteria for inclusion in the analysis, potential differences in the baseline characteristics cannot be ruled out.

Wider implications of the findings: Embryo development was more favorable in POSEIDON group 1, suggesting a direct relationship between oocyte quantity and quality, and that oocyte quality is determinant of embryo development. These show the reasonability of classifying POR by the POSEIDON criteria, providing information for the appropriate counselling of POR regarding their possible prognosis.

Study question: What are the prevalence and implications of cytoplasmic strings (Cyt-S) in preimplantation development after blastulation?

Summary answer: Cyt-S are common in human embryos and are associated with faster blastocyst development, larger expansion, and better morphological quality.

What is known already: Cyt-S are dynamic cellular projections connecting inner-cell-mass (ICM) and trophectoderm during blastocyst expansion. Their prevalence in human embryos *in vitro* has been estimated 44-93%. Currently, their role is unknown. Studies in animal models suggested they might be involved in ICM-to-trophectoderm communication or cell fate-related events. Nevertheless, comprehensive descriptions and clear definitions, evidence-based hypotheses about their function, and data about their clinical implications are lacking, limited or controversial. Here we leveraged time-lapse microscopy, artificial intelligence, and chromosomal testing to comprehensively portray these common features of blastulation and expansion processes.

Study design, size, duration: Observational study involving 124 PGT-A cycles in EmbryoScope (Vitrolife) with ≥1 blastocyst (N = 315) between May-2013 and November-2014. Timings from tSB to biopsy (t-biopsy, i.e., blastocyst full-expansion) in hours-post-insemination (hpi) and embryo area (including zona-pellucida in μm^2) were automatically annotated through an AI-based software (CHLOE™, Fairtility). One senior embryologist annotated Cyt-S presence, number, timings, and type (thick cell-to-cell connections and/or threads), and blastocyst collapses (i.e., reduction of embryo area preventing the discrimination of ICM from trophectoderm).

Participants/materials, setting, methods: ICSI, continuous blastocyst culture (day 5-7) in time-lapse incubators, trophectoderm biopsy without zona-pellucida drilling on fully-expanded blastocysts, and qPCR to assess non-mosaic full-chromosome aneuploidies were all conducted. Blastocyst morphological quality was defined according to Gardner's schemes as excellent (AA), good (AB,BA), average (BB,AC,CA) and poor (CC,BC,CB). Only vitrified-warmed euploid single-embryo-transfers were performed. Along with developmental timings, extent of expansion and morphological quality, we also assessed euploidy and live-birth rates in blastocysts with and without Cyt-S.

Main results and the role of chance: 94.4% of the patients (N = 117/124) had ≥1 embryo with Cyt-S (mean:2.2 ± 1.6, range:0-9). 86% of all blastocysts analyzed (N = 271/315) had ≥1 Cyt-S (3.5 ± 2.1, 1-13; duration of the longest Cyt-S: 5.8 ± 3.4 hours, 0.5-20.9). Overall, we analyzed 937 Cyt-S detected at 117.3 ± 11.8 hpi (85.7-160.5) and lasting 3.8 ± 2.7 hours (0.2-20.9). The first Cyt-S of each embryo lasted longer (4.4 ± 3.2 hours) compared to the following (≈3 hours or less). Cyt-S were mostly threads (N = 133/271, 54.2%) or thick cell-to-cell connections becoming threads (N = 382/937, 40.8%) than connections of constant diameter (N = 47/937, 5%). Of the 271 embryos with ≥1 Cyt-S, 71.9% showed these projections only during early expansion processes after tSB (N = 195; 3.0 ± 1.6, 1-10), 7.7% only after collapses (N = 21; 2.6 ± 1.5, 1-6), and 20.3% both in early expansion and after collapses (N = 55; 2.3 ± 1.3 and 3.2 ± 2.4, 1-11 respectively). Poor- versus excellent-quality blastocysts (N = 54/75, 72% versus N = 120/129, 93%, multivariate-OR=0.32, 95%CI 0.11-0.92, adjusted-p=0.03), t-biopsy (multivariate-OR=0.97, 95%CI 0.95-0.99, p = 0.05) and blastocyst area at t-biopsy (multivariate-OR=1.1, 95%CI 1.01-1.18, p = 0.02) were all associated with the prevalence of embryos with Cyt-S. Lastly, while euploidy rates were comparable between blastocysts with and without Cyt-S, an association instead was shown with live-birth-rates per vitrified-warmed euploid transfers (N = 34/77, 44.2% versus N = 0/10, 0%; p < 0.01), although these data are very preliminary.

Limitations, reasons for caution: Some Cyt-S after collapses might correspond to connections already present before these events. Larger datasets are required to confirm putative associations between Cyt-S and clinical outcomes. Only associations could be reported here, but not causations/consequences. Specific basic research studies are required to this end

Wider implications of the findings: Embryos with ≥1 Cyt-S were faster in reaching all blastocyst timings (tSB to t-biopsy) and to expand, achieved a larger area at t-biopsy and had a better morphology. These dynamic features of blastocyst expansion might be physiological and represent biomarkers of embryo quality. Nevertheless, their function is yet unknown

O-120 Predicting Embryo Ploidy Status Using Time-lapse Images

S. Rajendran[1], M. Brendel[1], J. Barnes[1], Q. Zhan[2], J. Malmsten[2], Z. Rosenwaks[2], M. Meseguer[3], N. Zaninovic[2], O. Elemento[1], I. Hajirasouliha[1]

[2]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York City, U.S.A.*
[3]*Health Research Institute la Fe, IVI Valencia, Valencia, Spain*

Study question: Can deep learning models using time-lapse images of embryo development be used to predict embryo ploidy and provide supplemental information to embryologists for clinical decision-making?

Summary answer: We developed a general MDBS-Ploidy model that uses time-lapse images and maternal age to predict embryo quality scores and ploidy status.

What is known already: Ploidy status, or the presence or lack of chromosomal abnormalities, is an important factor in a successful pregnancy. Embryos with abnormalities are classified as aneuploid, whereas those without are euploid. With the advent of artificial intelligence in computer vision and the collection of large IVF-related datasets combining images, videos, and clinical outcomes, a variety of methods have been developed to automatically assess embryo quality and other characteristics using images from time-lapse sequences. To our knowledge, a video classification model validated by heterogeneous data to predict both embryo quality score and ploidy is lacking.

Study design, size, duration: The training dataset for the model consisted of 1,998 time-lapse sequences captured by the Embryoscope®. Time-lapse image sequences consisted of around 360–420 frames captured during 5 days of development. PGT-A results were used as ground truth labels for all ploidy prediction tasks, with embryos classified as euploid or aneuploid. The dataset also included clinical information such as blastocyst score (BS) and maternal age at the time of oocyte retrieval.

Participants/materials, setting, methods: The MDBS-Ploidy consists of two steps. The first step is quality score prediction from day-5 time-lapse video input using a Bidirectional Long Short-Term Memory architecture with added output layers for multitasking. In the second step, the predicted score, in addition to maternal age, is used to predict the ploidy status of the embryo using a logistic regression model. We evaluated the performance of the MDBS-Ploidy using area under the receiver-operating-characteristic (AUROC) on a validation dataset.

Main results and the role of chance: For the MDBS-Ploidy quality score prediction module, the Pearson correlation between scores predicted by the MDBS-Ploidy and ground truth quality scores is 0.70 on the validation dataset, suggesting moderate correlation strength. As for the aneuploidy prediction module, the MDBS-Ploidy can discriminate between euploidy and aneuploidy with an AUROC of 0.76 ± 0.002. The MDBS-Ploidy performs comparably with a model trained on the embryologist-annotated blastocyst score. We replicate these comparative results in external validation datasets as well, namely the Embryoscope+® dataset with 1,000 embryos and the IVI Valencia Spain dataset with 543 embryos. Moreover, the MDBS-Ploidy is completely automated, requiring only time-lapse images from 96 to 112 hpi and maternal age to predict embryo ploidy status. This allows the MDBS-Ploidy to be adapted clinically without interrupting ongoing workflows. The MDBS-Ploidy also provides a certain level of explainability; embryologists can use the intermediate quality score (from the first module) to determine why an embryo is classified as a certain ploidy status. With a recall of 0.84 ± 0.004 for the validation dataset, the MDBS-Ploidy shows promise for successfully selecting euploid embryos. We believe that the MDBS-Ploidy can provide supplemental information for selecting the most viable embryo.

Limitations, reasons for caution: Our model primarily uses data from time-lapse microscopy. Clinics without access to this technology will be unable to use our model.

Wider implications of the findings: This model is clinically relevant for making decisions as to whether an embryo may be chromosomally normal. Automated quality score prediction is instrumental to embryologists who are

currently annotating embryos manually. Future iterations of the model can theoretically be adopted into clinical practice because it is end-to-end and fully automated.

Trial registration number: not applicable

O-121 Temporal development of scores from a time-lapse based artificial intelligence provides no additional benefit compared to the latest score

J. Lassen[1], F. Bahr[2], J. Rimestad[1], M. Johansen[1], J. Berntsen[1]

[1]*Vitrolife A/S, Product development, Aarhus, Denmark*
[2]*Vitrolife A/S, Product management, Aarhus, Denmark*

Study question: Does the temporal development of scores from an artificial intelligence (AI) based embryo selection model provide additional predictive power compared to the latest score?

Summary answer: Earlier predictions provide no additional predictive power given the latest prediction. Knowing the development of AI scores is thus not beneficial for embryo selection.

What is known already: Traditionally, embryo grading takes into consideration the final morphology score together with the history of embryo development events. Recent publications have shown that time-lapse based AI models trained on clinical outcomes can automatically rank embryos by the likelihood of implantation that equal or surpass traditional methods, without the necessity for manual evaluation. AI-based methods based on time-lapse data may account for the impact of the full temporal development on likelihood of implantation. In this study, we examine if the addition of previous scores adds to the performance of an embryo selection model.

Study design, size, duration: A retrospective multicenter study of transferred embryos (n = 2422) with known implantation data (KID) between 2012-2020 from 21 international clinics. Embryos were cultured in EmbryoScope time-lapse incubators for at least 5 days. Both single and multi-embryo transfers in fresh and warmed cycles were included. Embryos were classified as positive (KIDp) or negative (KIDn) by the presence of fetal heartbeat.

Implantation likelihood was evaluated at cleavage- and blastocyst stages by a 3D CNN model; iDAScore v2.0.

Participants/materials, setting, methods: A kernel-based conditional independence test was used to evaluate if a score at x hours post insemination (hpi) provide extra information compared to a score at y hpi. The test estimates the likelihood that a prediction after x hpi does not provide any additional information with regards to predicting KIDp when a prediction after y hpi is available. These likelihoods (p-values) were Bonferroni corrected to adjust for multiple comparisons.

Main results and the role of chance: KIDp predictions were computed for all embryos at 40, 44, 64, 68, 112, and 116 hpi corresponding to early and median time of transfer for day 2, 3, and 5. For all time points, the conditional independence test showed that there was no added information from knowing predictions at an earlier time point ($p > 0.21$).

Similarly, it was tested if a known later prediction will improve model performance for an earlier prediction. This was always the case ($p < 0.01$) except for predictions close in time (68 vs 64 hpi; $p = 1.0$) and (44 vs 40 hpi; $p = 1.0$). This may reflect that there was little additional embryo development information during a 4-hour period at this development stage.

The above shows that knowledge of the temporal score development does not improve model performance compared to using latest available score. This means that an AI model based on time-lapse videos likely considers earlier embryo development events in the context of the entire development history.

Limitations, reasons for caution: This study is a retrospective study that only looks at AI based on time-lapse videos. There is a potential bias as the embryos were likely of higher quality having been chosen for transfer. It is possible that the results do not generalize to simpler non-3D CNNs.

Wider implications of the findings: Knowing the temporal score development can introduce subjectivity that might lower implantation rates as the earlier scores were shown to not provide any significant prediction improvement.

Trial registration number: not applicable

[5]*Fairtility, Software Development, Tel Aviv, Israel*
[6]*Fairtility, Clinical Department, Tel Aviv, Israel*
[7]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Can an automatic AI scoring system predict ploidy, live birth and utilization? Are there differences in AI scoring between donor and own gametes?

Summary answer: CHLOE-EQ Score is directly associated with oocyte quality, ploidy, utilization, live birth, embryo quality, direct uneven cleavage (DUC), blastulation, utilization and selection for transfer.

What is known already: The integration of AI algorithms, such as CHLOE-EQ, into different Time-lapse systems requires clinical and biological validation. Geri Time-lapse videos have given the embryologists more insight into embryo development. Analyzing this information manually requires time and introduces risk of error. To tackle this issue, AI solutions like CHLOE-EQ (Fairtility) can be used to automatically assess video datapoints. CHLOE-EQ provides an embryo quality score that has been shown to predict embryo viability and ploidy, providing clarity on the underlying biological factors. Before introducing AI tools in clinical practice, it is crucial to confirm their efficacy and validate with clinical data.

Study design, size, duration: A retrospective cohort analysis was conducted at a private clinic in Spain from April 2021 to November 2022, involving the review of 3196 Geri time-lapse videos with a subset of known ploidy and live birth outcomes. The correlation of CHLOE-EQ score with ASEBIR clinic grading was evaluated. As well as with DUCs, oocyte quality, sperm source, blastulation, utilization, selection for transfer, ploidy and live birth.

Participants/materials, setting, methods: Geri time-lapse videos were automatically analyzed by CHLOE-EQ (Fairtility). CHLOE-EQ score was assessed in relation to laboratory (ploidy, clinic ASEBIR embryo scoring, utilization, selection for transfer) and clinical outcomes (live birth), as well as between own vs donor gametes (own eggs >40y vs donor eggs and testicular sperm vs donor sperm) using descriptive statistics and t-test. The accuracy of prediction was measured using binary logistic regression (AUC).

Main results and the role of chance: CHLOE-EQ score was positively correlated with ASEBIR embryo quality (A:8.7 ± 1.9, n = 349 >B:6.8 ± 2.9, n = 470 > C: 5.1 ± 3.0, n = 124 > D:1.3 ± 2.1, n=751; $p < 0.05$). Non-DUCs had higher CHLOE-EQ Score than DUCs [5.3 ± 3.8, n=1798 vs 1.9 ± 0.38, n=643, $p<0.001$]. CHLOE-EQ Score was unaffected by the quality of the sperm sample, with similar CHLOE-EQ scores between donor sperm and testicular derived sperm (4.1 ± 3.9, n=335 vs 3.4 ± 4.2, n=56, respectively, NS).

Embryos that blastulated (yes vs no: 5.4 ± 3.7, n=1996 vs 0.6 ± 2.1, n=309, $p < 0.001$), were utilized (7.4 ± 0.28, n=911, vs 1.0 ± 2.1, n = 1309, $p < 0.001$), selected for transfer (8.7 ± 2.4, n=153 vs 3.3 ± 3.7, n = 2067, $p < 0.001$), were euploid (7.5 ± 2.5, n=72 vs 6.3 ± 3, n=152, $p = 0.001$) and resulted in live births (4.4 ± 4.1, n = 332 vs 3.8 ± 4, n = 499, $p = 0.02$) had a higher CHLOE-EQ score than embryos that did not.

CHLOE-EQ Score is higher in embryos derived from oocytes from donors than own eggs, suggesting that oocyte quality affects CHLOE-EQ score (4.0 ± 4, n = 1189 vs 2.7 ± 3.4, n = 356).

CHLOE-EQ Score is predictive of utilization (AUC=0.95, n=2220, baseline=41%, p<0.001), euploidy (AUC=0.63, n=224, baseline=32.1%, p=0.003), blastulation (AUC=0.94, n = 2305, baseline=86.6%, p < 0.001) and selection for transfer (AUC=0.89, n = 2220, baseline=41%, p<0.001).

Limitations, reasons for caution: This is a retrospective single-center study in which embryos for transfer were selected by human embryologists, and forms part of program to validate the responsible integration of AI into clinical practice in each individual clinic.

Wider implications of the findings: This is the first study presenting the efficacy of prediction of CHLOE-EQ with GERI data. AI tools have the potential to improve consistency, efficiency, and accuracy of embryo assessment and selection. CHLOE-EQ predicts through quantitative and qualitative morphological and morphokinetics information, resulting in more personalized care for each individual embryo.

Trial registration number: not applicable

O-123 Time lapse incubation and morphokinetic embryo evaluation are not enough. Results from a Randomized controlled PILOT study

G. Sacks[1], H. Mozes[1], E.G. Talia[1], O. Schonberger[1], R. Ronn[1], I. Ben-Ami[1], N. Srebnik[1]

[1]*Shaare Zedek Medical Center Hebrew University Medical school, In Vitro Fertilization, Jerusalem, Israel*

Study question: Does the TLI have an added value in reproductive outcome when separating the system's two components, undisturbed culturing, and morphokinetic embryo grading?

Summary answer: The TLI system itself does not have a significant added value. More advanced algorithms should be applied to aid in embryo selection process.

What is known already: The TLI technology has been widely used for over two decades for embryo culturing. A Cochrane meta-analysis found no significant difference in clinical pregnancy rate using TLI compared to conventional incubators. Another RCT concluded that the addition of TLI morphokinetic data did not significantly improve clinical reproductive outcomes. On the other hand, the benefit of TLI is the identification of abnormal cleavage dynamics and analysis of other morphokinetic parameters although no proven increase in pregnancy rate was shown. Several Artificial intelligence algorithms use TLI data to increase the pregnancy rate and embryo selection process.

Study design, size, duration: A prospective, randomized, double-blinded, single-center, controlled study.

After applying inclusion criteria, 102 women were included in the analysis, 34, 32, and 36 in arms 1,2, and 3 respectively, with a total of 1061 embryos evaluated, 420 in arm 1, 285 in arm 2, and 356 in arm 3. Patients were recruited between November 2017- July 2020.

Participants/materials, setting, methods: University-affiliated Medical Centre in vitro fertilization (IVF) clinic.

Patients were randomized into 3 groups: 1) conventional incubator with morphological evaluation only; 2) TLI incubator with both morphological and morphokinetic evaluation; 3) TLI incubation with morphological evaluation only. All were cultured in MIRI ESCO incubators. The primary outcome was live birth rates. Secondary outcomes were clinical pregnancy rates and cumulative pregnancy rates. Embryo quality and morphokinetic scores.

Main results and the role of chance: No differences were found in the rated day 2 top quality embryos (TQE), day 3 TQE or blastocyst stage TQE, and a similar number of embryos were suitable for either transfer or cryopreservation between the groups. On the other hand, higher rates of multinucleation were found in group 1 (31.9 ± 6 vs. 16.6 ± 5 vs.14.9 ± 5, p = 0.03 for groups 1,2 and 3 respectively).

Regarding primary outcome, we did not find any significant difference in live birth rate between the groups, neither for single embryo transfer cycles (SET) (35% vs. 31.6% vs. 24%, p = 0.708) nor for double embryo transfer cycles (DET) (41.7% vs. 38.5% vs. 36.4%, p = 0.966 for groups 1,2 and 3 respectively). Also, no differences were noted between pregnancy rates and clinical pregnancy rates. After concluding the first part of the study, embryos in arm 3 were retrospectively reevaluated, gaining additional morphokinetic data for the embryo selection process. In more than half of the embryos selected for transfer, the morphokinetic and morphologic evaluations were similar. For the additional 32 embryos from a total of 12 cycles, there was a discrepancy between the grades. In the other cases, the use of morphokinetic scoring would not have changed significantly the end point of pregnancy.

Limitations, reasons for caution: The pandemic affected patient recruitment and smaller numbers than intended were achieved leaving the study sample underpowered for the primary endpoint. Both day 3 and day 5 transfers were performed, and cycles were not always restricted to single embryo transfer, although the study was designed as such.

Wider implications of the findings: This study underlines the maybe unjustified morphkinetic scoring grading system which requires much time and attention from the embryologist to view and annotate and should be reconsidered especially with the rise of substitute software-assisted assessment algorithms showing an additional advantage in embryo selection and implantation rate.

Trial registration number: ClinicalTrials.gov Identifier: NCT02657811.

O-130 Initiation of ovarian stimulation in the late follicular phase, a randomized controlled trial

S. De Rijdt[1], **K. Illingworth**[1], **N. De Munck**[1], **H. Tournaye**[1], **S. Mackens**[1], **M. De Vos**[1], **C. Blockeel**[1]

[1]*UZ Brussel, Brussels IVF, Jette, Belgium*

Study question: Does late follicular phase stimulation yield similar outcomes compared with conventional early follicular phase stimulation in a GnRH antagonist protocol in oocyte donors?

Summary answer: Late follicular phase stimulation is not inferior in terms of number of oocytes compared to early follicular phase stimulation in a GnRH antagonist protocol.

What is known already: In patients undergoing fertility preservation for medical reasons, late follicular phase stimulation has been effectively used, resulting in similar numbers of total and mature oocytes obtained, oocyte maturation rate, mature oocyte yield, and fertilization rates compared to conventional early follicular phase ovarian stimulation. Because of LH suppression by endogenous progesterone in the luteal phase, there is less need for the use of a GnRH antagonist.

Study design, size, duration: This is an open label, phase 3, non-inferiority, randomized controlled trial using a two-arm design with 1:1 allocation ratio. The study included 71 oocyte donors between 18 and 36 years, with a regular menstrual cycle length and BMI 19-35 kg/m2, who underwent ovarian stimulation between November 2018 and May 2022. Patients were allocated to either early follicular start (Group A, n = 36), or to late follicular start (Group B, n = 35).

Participants/materials, setting, methods: In Group A, patients followed a fixed GnRH antagonist protocol with r-FSH 225IU daily. In Group B, r-FSH 225IU daily was initiated when a dominant follicle and late follicular hormonal values were observed, a GnRH antagonist was added if serum LH-levels were >10IU/L. The primary outcome was number of cumulus-oocyte-complexes (COCs). Secondary endpoints included number of mature oocytes, consumption of gonadotropins, duration of ovarian stimulation, days of GnRH antagonist used, and cost of the stimulation.

Main results and the role of chance: Using an intention-to-treat analysis, the total number of oocytes did not differ between Group A and Group B (17.7 ± 10.0 vs 17.2 ± 9.1, p = 0.82, difference 0.49 ,95% CI (-4.04 to 5.03)). In the per protocol analysis, after excluding 4 patients, there was no difference between Group A and Group B (18.2 ± 9.7 vs 18.8 ± 7.8, p = 0.62, difference -0.6, 95% CI (-4.9 to 3.7)).The number of mature oocytes did not differ between Group A and Group B (14.1 ± 8.1 vs 12.7 ± 8.5, p = 0.48). In none of the treatment arms OHSS was observed. The duration of stimulation was shorter in Group A than in Group B (10.0 ± 1.6 vs 10.9 ± 1.5 days, p = 0.01). The total amount of r-FSH used was lower in group A than in Group B (2240.7 ± 313.9 IU vs 2453.9 ± 330.1 IU p = 0.008). A GnRH antagonist was used for approximately 6 days in Group A, while in group B, only in one patient a GnRH antagonist was prescribed for 4 days (6.0 ± 1.4 days vs 0.13 ± 0.7 days p < 0.001). There was a significant difference in total medication cost per cycle between both protocols (1147.9 ± 182.8 € in Group A, vs 979.9 ± 129.0 € in group B, p < 0.001), i.e. a cost reduction of 15% for Group B as compared with Group A.

Limitations, reasons for caution: A limitation of the study is the lack of embryology data. Because of adaptations in the oocyte donation program in our center over the years, this study contains a mix of fresh and frozen donation cycles, leading to a very heterogenous group, making correct interpretation of the embryology data difficult.

Wider implications of the findings: Late follicular phase stimulation is as efficient as early follicular phase stimulation in terms of number of oocytes. It is patient-friendly, with reduced cost and reduced number of injections.

Study question: How does a long GnRH agonist versus a GnRH antagonist protocol affect ovarian response when using individualised fixed daily follitropin delta dose for ovarian stimulation?

Summary answer: BEYOND trial data demonstrates that individualised follitropin delta dosing is safe and effective in a long GnRH agonist protocol in women with AMH ≤35 pmol/L.

What is known already: Efficacy and safety of a fixed daily dose of follitropin delta, individualised based on bodyweight and anti-Müllerian (AMH), have been established in RCTs using a GnRH antagonist protocol. Preliminary study data shows that individualised follitropin delta is efficacious when used with a long GnRH agonist protocol (RAINBOW trial). There is no comparative data for efficacy and safety of individualised follitropin delta in a long GnRH agonist versus an antagonist protocol.

Study design, size, duration: This was a randomised, controlled, open-label, multi-centre trial comparing efficacy and safety of individualised follitropin delta dosing in a long GnRH agonist versus an antagonist protocol in participants undergoing their first ovarian stimulation for IVF/ICSI conducted between May 2019 and February 2022. The primary endpoint was the number of oocytes retrieved. Important secondary endpoints included ongoing pregnancy rates and adverse drug reactions, with a special focus on OHSS. A total of 437 participants were randomised.

Participants/materials, setting, methods: Participants, 18–40 years old with AMH ≤35 pmol/L, were enrolled at specialist reproductive health clinics in Austria, Denmark, Israel, Italy, the Netherlands, Norway and Switzerland. The mean number of oocytes retrieved was compared between the agonist and antagonist protocols using a negative binomial regression model with age and AMH at screening as factors. The analyses were based on all randomised subjects, using a multiple imputation method for randomised subjects withdrawing before start of stimulation.

Main results and the role of chance: Of the 437 randomised subjects, 202 and 204 initiated ovarian stimulation with follitropin delta in the agonist and antagonist groups, respectively. Baseline mean data were: age, 32.3 ± 4.3 years; AMH, 16.6 ± 7.8 pmol/L, respectively. The number of oocytes retrieved was statistically significantly higher in the agonist (11.1 ± 5.9) versus antagonist (9.6 ± 5.5) group, with an estimated mean difference of 1.31 oocytes (95% CI:

0.22; 2.40, p = 0.0185). The difference in number of oocytes retrieved was influenced by the patients' age and ovarian reserve, with a greater difference observed in patients <35 years and patients with high ovarian reserve (AMH >15 pmol/L). Cycle cancellations (2.0% versus 3.4%) and transfer cancellations (13.7% versus 14.7%) were similar in both groups. Ongoing pregnancy rate (36.9% vs 29.1%; estimated difference: 7.74% [95% CI: −1.49; 16.97, p = 0.1002]) and other pregnancy outcomes were higher in the agonist versus antagonist protocol group, but the differences were not statistically significant. The most commonly reported adverse events (≥1% in either group) were similar in both groups (headache, OHSS, nausea, pelvic pain or discomfort, and abdominal pain). Incidence of early moderate/severe OHSS was low (1.5% versus 2.5%). Early pregnancy loss was similar between the groups (20% vs 24% of subjects with positive beta-hCG test, respectively).

Limitations, reasons for caution: Subjects with AMH >35 pmol/L were not enrolled. Clinicians should remain cautious when using a GnRH agonist protocol in patients with AMH >35 pmol/L (greater OHSS risk). OHSS incidence in the GnRH antagonist group may have been lower if a GnRH agonist trigger had been allowed.

Wider implications of the findings: In women with AMH ≤35 pmol/L, a fixed daily dose of follitropin delta (individualised according to bodyweight and AMH) showed similar efficacy when used in a long GnRH agonist protocol with no additional safety signals observed and no additional risk of OHSS versus follitropin delta used in an antagonist protocol.

O-132 Comparison of pregnancy rates in antagonist cycles after luteal support with GnRH-agonist versus progesterone – prospective randomized study

E. Buhbut[1], I. Ben-Ami[1], R. Nabulsi[1], G. Avigdor[1]

[1]*Sharre zedek madical center, IVF Unit, jerusalem, Israel*

Study question: Are pregnancy rates in GnRH-antagonist cycles triggered with hCG and luteal phase support (LPS) with intranasal GnRH-agonist or vaginal progesterone comparable?

Summary answer: Nasal GnRH-agonist for LPS is associated with higher pregnancy rates compared with standard progesterone support in antagonist-based cycles triggered with hCG

What is known already: Regardless of its mechanism of action, the use of GnRH-a during the luteal phase in addition to progesterone, either in a single or multiple doses, has become a common practice as a part of ART protocols, based on its association with higher pregnancy and live birth rates . Its use as a sole agent for LPS has not gained the same popularity although studies supporting non-inferiority and even higher live birth rates with GnRH-a as a sole LPS agent have been published.

Study design, size, duration: A single-center, prospective, randomized study. A total of 150 patients underwent 164 GnRH-antagonist-based IVF cycles triggered with hCG and fresh embryo transfer. The study was conducted between June 9th, 2020, and May 5th, 2022.

Participants/materials, setting, methods: The study was conducted in the IVF clinic at University-affiliated tertiary medical center. Patients meeting the inclusion criteria who underwent antagonist-based IVF cycles and hCG triggering were enrolled. Computer-based randomization (1:1 ratio) was performed on the day of oocyte pickup (OPU). In both groups LPS was initiated on the evening of the OPU day with either GnRH-agonist nasal spray (Nafareline, nasal spray 200 mcg twice daily)or vaginal micronized progesterone (Utrogestan 300 mg, 3 times daily).

Main results and the role of chance: A total of 150 patients underwent 164 cycles, 127 cycles of which were included in the study cohort. Of them, 64 (50.4%) and 63 (49.6%) cycles were treated with GnRH-agonist or progesterone respectively as sole luteal phase support. A significantly higher pregnancy rate was found in the GnRH-a group compared with the progesterone group (43.8% versus 25.4% respectively; P = 0.030). After adjustment of several potential confounders such as age, body mass index (BMI), past obstetric history, number of IVF cycles, oocytes retrieved and embryos transferred, GnRH-agonist was still associated with a higher pregnancy rate (odds ratio 3.4, 95% confidence interval 1.4-8.3). Ovarian hyperstimulation syndrome (OHSS) rates were similar between the groups. Significantly higher progesterone levels were measured at β-hCG testing day in the GnRH-a group, both for the cleavage stage embryos (129.1 ± 23.7 nmol/L vs. 97.7 ± 48.9 nmol/L, P = 0.024) and for the blastocysts (127.2 ± 0.1 nmol/L vs. 75.3 ± 49.1 nmol/L, P = 0.034).

Limitations, reasons for caution: This study is not powered for analysis of clinical pregnancy rates, live birth rates and pregnancy outcomes. Larger studies are needed for research of these outcomes.

All patients participating were at low risk for OHSS, therefore the study is underpowered to find significant differences in early or late OHSS.Wider implications of the findings: Our findings suggest that intranasal GnRH-agonist administration as a sole luteal support in antagonist-based IVF cycles triggered with hCG results in higher pregnancy rates in comparison with traditional irritating vaginal preparations while not mandating additional support in the first weeks of pregnancy.

O-133 Follicular flushing increases the number of cumulus oocyte complexes retrieved. A Randomized Controlled Trial

G. Lainas[1], T. Lainas[1], A. Makris[1], M. Xenariou[1], I. Zorzovilis[1], G. Petsas[1], E. Kolibianakis[2]

[1]*Eugonia IVF Unit, Unit of Assisted Reproduction, Athens, Greece*
[2]*Unit of Human Reproduction, 1st Dept of Ob/Gyn- Aristotle University of Thessaloniki, Thessaloniki, Greece*

Study question: Does follicular flushing increase the number of cumulus oocyte complexes (COCs) retrieved compared to single aspiration?

Summary answer: Follicular flushing increases the number of COCs retrieved compared to single aspiration.

What is known already: On the basis of published meta-analyses, follicular flushing does not seem to increase the number of COCs retrieved and the probability of pregnancy. However, eligible RCTs in these meta-analyses are characterized by significant heterogeneity regarding the population studied, the needle type and lumen diameter, the aspiration pressure and the number of flushing attempts performed. Moreover, most of the studies do not offer information regarding the flow rate of the aspiration system used. A constant flow rate has been employed in a single RCT, in which a higher number of COCs was retrieved after follicular flushing compared with single aspiration.

Study design, size, duration: This is a single-center, randomized controlled trial, performed between July and December 2022. One hundred and five patients undergoing oocyte retrieval for intracytoplasmic sperm injection, aged <43 years, with BMI 18-35kg/m2 were included in the study. Random allocation of each ovary to flushing or single aspiration was performed by a study nurse on the day of oocyte retrieval, using a computer generated randomization list. Patients could enter the study only once.

Participants/materials, setting, methods: All follicles ≥11 mm were aspirated with the same double-lumen needle, using the same aspiration pressure (190 mmHg) to achieve a flow rate of 0.42 ml/sec. If no COC was found in the initial aspirate, flushing was performed in the corresponding group until a COC was retrieved, or up to a maximum of five times. The primary outcome measure was the number of COCs retrieved per ovary randomized. Values are expressed as median (interquartile range).

Main results and the role of chance: Significantly more COCs were retrieved per ovary randomized in the follicular flushing versus the single aspiration group, in all patients [5 (7) versus 2 (3), p < 0.001, respectively], in patients with high [9 (3) versus 5 (4), p < 0.001, respectively], normal [5 (2) versus 2 (3), p < 0.001, respectively] and low [1 (1) versus 1 (1), p < 0.001, respectively] ovarian response. No COCs were retrieved in 2.9% of the ovaries in the flushing group versus 16.2% of the ovaries in the single aspiration group (p < 0.001).

The oocyte retrieval rate, which was defined as the ratio of COCs retrieved to the number of aspirated follicles ≥11 mm, was significantly higher in the follicular flushing versus the single aspiration group, in all patients [88.9% (25) versus 45.5% (37.5), $p < 0.001$, respectively], as well as in patients with high [81.8% (15.1) versus 45.5% (25.0), $p < 0.001$, respectively], normal [85.7% (28.6) versus 40% (30.0), $p < 0.001$, respectively], and low [100% (0) versus 50% (100), $p < 0.001$, respectively] ovarian response.

No significant differences were observed regarding maturation rate, fertilization rate and the proportion of good quality embryos on day 2 in all patients as well as in patients with high, normal and low ovarian response.

Limitations, reasons for caution: The current study design, by randomizing ovaries instead of patients, eliminates heterogeneity attributed to multiple confounders and allows a more accurate evaluation of the true effect of follicular flushing on the number of COCs retrieved. However, it does not allow the detection of its effect on the probability of pregnancy.

Wider implications of the findings: This is the first RCT to show that follicular flushing increases the number of COCs retrieved compared to single aspiration, independently of ovarian response. The data presented suggests that follicular flushing plays an important role in increasing the efficacy of oocyte retrieval.

Trial registration number: NCT 05473455

Study question: Does luteal estradiol pretreatment improve the number of oocytes retrieved in women aged 38 to 43 years treated in antagonist protocol with corifollitropin alfa?

Summary answer: Programming antagonist cycles with luteal estradiol did not increase the number of retrieved oocytes in advanced age women, however it was effective for programming.

What is known already: Previous studies showed that programming IVF cycles with estradiol pretreatment is a valuable tool for the organization of IVF centers and patients. However, variable effects of estradiol pretreatment were observed on the number of retrieved oocytes: no difference in normal responders, improved yield in oocyte donors and conflicting results in poor responders but no improvement in those fulfilling the bologna criteria. In advanced age women, recruitable follicles tends to decrease in number and to be more heterogeneous in size but it remains unclear if estradiol pretreatment could yield more oocytes through its negative feed-back effect on FSH intercycle rise.

Study design, size, duration: This non-blinded randomized controlled trial was conducted between 2016 and 2022. Participants were 324 women aged 38 to 43 years who requested IVF treatment. The primary endpoint was the comparison of the total number of retrieved oocytes between pretreated (P) and no pretreated (NP) patients. Secondary endpoints were duration and total dosage of recombinant FSH, cancellation rate, total number of metaphase II oocytes and obtained embryos, fresh transfer live birth rate (LBR) and cumulative LBR.

Participants/materials, setting, methods: This multicentric study (6 centers) enrolled women with regular cycles, weight >50 kg and BMI <32, IVF rank 1-2. According to computerized randomization, micronized estradiol 2mg twice a day was started on day (D) 20-24 continued until Wednesday beyond the onset of menses followed by administration of corifollitropin alfa on Friday i.e. stimulation (S)1 or from D1-3 of a natural cycle in unpretreated patients. GnRH antagonist was started at S6 and additional rFSH at S8.

Main results and the role of chance: Basal characteristics were similar in estradiol P (n = 147; number (mean [SD]) of treatment days 9.8[2.6]) and NP patients (n = 144), both displaying however a wide range of AMH levels (0.3 to 11.6 ng/ml) for advanced age patients. The cancellation rate showed a trend to be lower in P group (11 vs 19 %, $p = 0.11$). The mean number of retrieved oocytes was lower in P compared to NP patients (8.4[6.1] vs 9.1[6], respectively). The treatment difference was -0.7[-2.1 ;0.8] $p = 0.03$ one tailed test . No significant differences were observed in the number of MII oocytes (7[5.5] vs 7.3[5.2], $p = 0.72$) and the number of obtained embryos (5[4.6] vs 5.2[4.2], $p = 0.60$) between the two groups. Oocytes retrieval was more often on working days in P patients (91.9 vs 74.2 %, $p < 0.001$). However, the duration of stimulation was significantly longer (11.7[1.7] vs 10.8[1.8] days, $p < 0.001$) and the extra rFSH dosage in addition to corifollitropin alfa was significantly higher (1040[548] vs 778[504] IU, $p < 0.001$) in P than NP patients. The LBR after fresh transfer in P patients (16.2%[16/99]) was not significantly different from that in NP patients (18.5%[17/92]), $p = 0.82$, nor the cumulative LBR per patients 19.1 % vs 26.4 %, $p = 0.16$ respectively.

Limitations, reasons for caution: Our stimulated women older than 38 years obtained a wide range of collected oocytes (0 to 29) suggesting very different stages of ovarian aging in both groups. Estradiol pretreatment is more susceptible to increase oocyte yield at the stage of ovarian aging characterized by asynchrony of a reduced follicular cohort

Wider implications of the findings: Programming antagonist cycles with luteal estradiol pretreatment is effective in advanced age women to better schedule oocyte retrievals on working days. However, the potential benefit on the number of collected oocytes remains to be demonstrated in a more selected population displaying the characteristics of Poseïdon groups 3 and 4.

O-135 Application of AMH determination in preoperative evaluation of micro-TESE in NOA patients

J. Zhang[1], J. Chen[1], G. Liu[1], L. Zhao[1], C. Fang[1], X. Liang[1]

[1]*the Sixth Affiliated Hospital- Sun Yat-sen University, Reproductive Medicine Research Centre, Guangzhou- Guangdong, China*

Study question: To investigate the value of anti-Müllerian hormone(AMH) determination for estimating the sperm retrieval rate(SRR) of microdissection testicular sperm extraction(micro-TESE) in non-obstructive azoospermia(NOA) patients.

Summary answer: NOA with low AMH would have more opportunity to present heterogeneous seminiferous tubules when micro-TESE was performed and had higher SRR, especially in idiopathic cases.

What is known already: For infertile patients with NOA, micro-TESE is considered to have higher SRR than traditional surgery methods. However, serum inhibin B, follicle-stimulating hormone (FSH) and various clinical parameters are not reliable predictors for the presence of focal spermatogenesis and SRR. In male, AMH is a glycoprotein secreted by Sertoli cells and facilitate the regression of Müllerian structures in the developing foetus. It is still controversial that whether AMH level has value to predict the SRR of micro-TESE.

Study design, size, duration: This was a retrospective case-control study. From September 2014 to May 2022, 502 NOA patients treated with micro-TESE were divided into different groups according to their surgery outcome and seminiferous tubules appearance. Age, testis volume, serum AMH, FSH and testosterone level were compared between the different groups. The differences of SRR and AMH level in NOA patients with different etiologies were also compared.

Participants/materials, setting, methods: Micro-TESE was performed at x10 to x20 magnification. An attempt was made to identify seminiferous tubules that were larger and more opaque than others. The procedure was terminated when sperm were retrieved. If all tubules were seen to have an identical appearance, at least three samples (upper, middle, and lower) were extracted. Venous blood samples were drawn from each patient (7–10 AM) after an overnight fast. FSH and AMH were measured by electrochemiluminescence immunoassay.

Main results and the role of chance: Testicular sperms were successfully retrieved in 270 cases (SRR=53.8%). There were no statistical differences in age, testicular volume, FSH and testosterone levels between the patients who succeeded and failed to obtain sperm (all $P>0.05$). The patients who obtained sperms had lower serum AMH level than those without sperm [0.81(0.16, 3.26)μg/L vs.1.37(0.21, 4.84)μg/L, $P<0.05$]. Patients with orchitis or AZFc deletion, cryptorchidism, KS, idiopathic azoospermia would have different AMH level [0.15(0.01, 0.41)μg/L, 5.71(3.57, 8.26)μg/L, 2.29(1.36, 3.81)μg/L, 0.15(0.05, 0.39)μg/L, 2.46(0.75, 5.49)μg/L, $P<0.05$]. Idiopathic azoospermia patients who obtained sperms had higher age but lower testosterone and AMH level than those without sperm [(35.2 ± 8.9) years vs. (32.5 ± 5.5) years, $P<0.05$, (3.1 ± 1.4)μg/L vs. (3.7 ± 2.1)μg/L, $P<0.05$; 1.63(0.35, 3.84)μg/L vs.3.00(1.20, 6.68)μg/L, $P<0.05$], there were no statistical differences in testicular volume and FSH level between the two groups ($P>0.05$). Receiver operating characteristic (ROC) curve showed that cut-off of serum AMH for successful sperm retrieval of idiopathic azoospermia patients was determined to be 2.96, with a sensitivity of 0.710 and specificity of 0.523, area under the curve (AUC) was 0.649. In the cases presenting heterogeneous seminiferous tubules during micro-TESE had lower AMH level and higher SRR than those presenting homogeneous seminiferous tubules [0.55(0.12, 2.05)μg/L vs.2.99(0.76, 6.11)μg/L, 75.9%(236/311)vs. 17.8%(34/191), all $P<0.05$].

Limitations, reasons for caution: Pathology analysis should be involved in the following study. Randomized controlled trial comparing micro-TESE and traditional TESE would demonstrate that whether idiopathic azoospermia patients with higher serum AMH level would have less benefit by microsurgery than patients with lower AMH level.

Wider implications of the findings: Recently, in our pathologic research, NOA patients with extremely lower serum AMH level were observed to have more opportunity to present severe hyalinization in their seminiferous tubules. Tubules with severe hyalinization have less Sertoli cells and seem very thin. Therefore, tubules with spermatogenesis would be easy to identify during micro-TESE.

Trial registration number: not applicable

Study question: Could microRNA profiling be a useful tool towards better understanding the pathophysiological mechanisms leading to non-obstructive azoospermia (NOA) due to maturation arrest?

Summary answer: MicroRNA profiling may be an efficient method towards unveiling maturation arrest pathophysiology as microRNAs constitute master posttranscriptional regulators of cell-cycle control during spermatogenesis.

What is known already: Non-obstructive azoospermia constitutes the most severe form of male factor infertility, affecting approximately 10% of infertile men. According to the histological subtype, NOA is classified into three main categories namely hypospermatogenesis, maturation arrest, and Sertoli-cell only syndrome. Maturation arrest is one of the most complex forms of NOA characterized by failure of spermatogenesis. Despite advances, the pathophysiology of maturation arrest remains a conundrum rendering management complex. Recent studies indicate that alterations on microRNA expression patterns could lead to maturation arrest. Mapping microRNA profiling and highlighting dysregulated pathways of maturation arrest cases may lead the way forward.

Study design, size, duration: A systematic review was performed in PubMed/Medline and Embase up to April 2022. Only full-length original studies in humans were included. Strict inclusion-exclusion criteria were applied aiming to isolate studies comparing microRNA profiling between maturation arrest cases versus normal fertile men, and/or men with obstructive azoospermia (OA). Following study selection, data on altered microRNA expression patterns were analyzed to underline differences between the abovementioned groups. Subsequently, in-silico analysis was performed to compare affected gene pathways.

Participants/materials, setting, methods: The studied population consisted of maturation arrest cases. Control groups consisted of men with normal spermatogenesis and/or men with OA. Predicted microRNA–target pairs were retrieved from microT-CDS, while a 0.8 cutoff threshold was applied. The GTEx repository was used to identify microRNA-targeted genes in the testis. Annotations derived from Ensembl and miRbase. Gene-set enrichment analysis was performed employing the KEGG-database. Fisher's exact test was performed in R package limma, setting a 0.01 p-value threshold.

Main results and the role of chance: Ten studies reported altered microRNA expression patterns in maturation arrest versus normal spermatogenesis cases and six studies in maturation arrest versus OA cases. Considering the maturation arrest-normal spermatogenesis arm, analysis revealed that eight microRNAs, which were upregulated in maturation arrest cases, namely hsa-miR-449a, hsa-miR-370-3p, hsa-miR-10b-3p, hsa-miR-539-5p, hsa-miR-22-5p, hsa-miR-605-5p, hsa-miR-491-3p and hsa-miR-302d-3p, affected 106 statistically significant gene-targets in the testis. The three most significantly affected pathways included the "microRNAs in cancer" pathway (55 affected genes, p-value <0.001), the "EGFR tyrosine kinase inhibitor resistance pathway" (29 affected genes, p-value = 0.007), and the "Hedgehog signaling pathway" (22 affected genes, p-value=0.008). Regarding the second arm of maturation arrest-OA, functional analysis indicated that four microRNAs, presenting to be downregulated in maturation arrest cases, namely hsa-miR-181a-5p, hsa-miR-449a, hsa-miR-182-5p and hsa-miR-138-5p, affected 421 statistically significant gene-targets in testis. The three most significantly affected pathways included the "pathways in cancer" pathway (86 affected genes, p-value =0.009), the "microRNAs in cancer" pathway (48 affected genes, p-value < 0.001), and the " cGMP-PKG signaling" pathway (36 affected genes, p-value=0.008). In summary, microRNAs affect the expression of master genes regulating cell-cycle and maturation processes during spermatogenesis, leading to maturation arrest as well as to other associated pathologies, including cancer.

Limitations, reasons for caution: The limited number of the included studies, as well as the small size population characterizing the great majority of them, constitute the main limitations of this study. Another reason for caution is the great heterogeneity observed among the studies regarding the molecular methods employed for microRNA profiling.

Wider implications of the findings: Data presented herein indicate that microRNA functional analysis may be a significant tool towards better understanding the pathophysiological basis of spermatogenesis maturation arrest, indicating future personalized diagnostic and therapeutic targets. Moreover, microRNA analysis may also constitute an efficient method of evaluating predisposition of NOA patients to other pathologies including cancer.

O-138 Factors influencing sperm retrieval rate of microdissection testicular sperm extraction in nonobstructive azoospermia patients with different etiologies: a retrospective study of 3104 patients

L. Zhang[1], R. Li[2], P. Liu[2], K. Hong[3]

[1]li.zhang, Department of Obstetrics and Gynecology, Beijing, China
[2]Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China
[3]Peking University Third Hospital, Department of Urology, Beijing, China

Study question: What are predictors of successful sperm retrieval (SRR) with microdissection testicular sperm extraction (mTESE) in men with non-obstructive azoospermia (NOA) according to different etiologies?

Summary answer: Predictors for SRR were different in patients with various etiologies and effects of age on SRR in idiopathic NOA and KS patients were opposite.

What is known already: NOA patients due to spermatogenic dysfunction, accounting for about 60 percent of the total azoospermia cases, may have opportunities to obtain sperm by mTESE and overall SRR of mTESE in NOA patients is about 50%. There were some of predictive factors for SRR at mTESE including age, testis volume, serum follicle stimulating hormone (FSH), testosterone (T), inhibin B, anti-Mullerian hormone and testicular histopathology, while the predictive factors of SRR remains underappreciated, especially in accordance with different type of etiology. Most notably, there are some controversies about the relationship between SSR and age at mTESE surgery.

Study design, size, duration: This retrospective study involved 3104 NOA patients with different etiologies treated with the first mTESE at the Reproductive Medical Centre of Peking University Third Hospital from March 2012 to December 2022.

Participants/materials, setting, methods: 3104 NOA patients were classified into seven groups according to etiologies including 1530 males with idiopathic NOA (iNOA), 763 males with Klinefelter syndrome (KS), 345 males with microdeletion of the AZFc, 177 cases with the history of cryptorchidism, 131 with a history of mumps orchitis, 89 males with cryptozoospermia and 69 cases with other causes. The end-point was the presence of one or more sperm. Multi-variable logistic regression was used to analyze sperm retrieval outcome.

Main results and the role of chance: Overall SRR was 43.46%, and there were different SRR in NOA patients with various etiologies with highest SRR of 89.31% in patients with a history of mumps orchitis and lowest SRR of 29.35% in iNOA patients. For patients with a history of mumps orchitis, there was a negative relationship between T and SRR (0.805 [0.654, 0.991] p = 0.041). For cryptozoospermia patients, shorter infertility duration was predictive for successful SRR (0.837 [0.704, 0.995], p = 0.044). Males with bigger testes had more likelihood of positive SRR (1.077 [1.005; 1.153], p = 0.035) in patients with cryptorchidism. BMI was an independent factor of SRR in AZFc-deleted patients (1.084 [1.013, 1.161], p = 0.020). For KS patients, lower male age (0.938 [0.898, 0.979], p = 0.004) and bigger testes (1.214[1.099, 1.342], p<0.001) were predictive for successful SRR. Lower levels of FSH (0.984[0.970, 0.998] p = 0.025) and higher male age(1.079[1.050, 1.110], p<0.001) were predictive for successful sperm retrieval in iNOA patients. So, the optimum age range of iNOA male undergoing mTESE should be 30 to 35 years old with the SRR of 29.13% when considering low SRR of iNOA males aged<30 years (23.96%) and the negative effect of female age on ICSI outcome.

Limitations, reasons for caution: Surgeon performing mTESE maybe another predictor for SRR which is a potential selection bias. Inhibin B and Anti-Müllerian hormone weren't included due to limited information in our database. We couldn't verify the conclusion in more population from multicenter despite the current study with the large sample size so far.

Wider implications of the findings: Our results provide valuable information for NOA patients who want to counsel surgeons about their treatments to help patients and surgeons to perform a shared decision-making for optimal therapy methods, especially about optimal age treated with mTESE in iNOA and KS patients.

Trial registration number: not applicable

O-139 Testicular mosaicism in non-mosaic Klinefelter Syndrome patients with focal spermatogenesis

S. Gül[1,2], V. Vloeberghs[3], H. Tournaye[1,3], E. Goossens[1]

[1]*Vrije Universiteit Brussel VUB, Biology of the testis lab, Brussels, Belgium*
[2]*Malatya Turgut Özal University, Histology and Embryology, Malatya, Turkey*
[3]*Vrije Universiteit Brussel VUB, Universitair Ziekenhuis Brussel UZ Brussel- Brussels IVF, Brussels, Belgium*

Study question: Do testis-specific cells have a normal karyotype in regions with spermatogonia (SPG) and ongoing spermatogenesis in non-mosaic Klinefelter Syndrome (KS) patients?

Summary answer: While SPG and Sertoli cells (SC) have 46,XY karyotype in regions with spermatogenesis, most Leydig cells (LC) and peritubular myoid cells (PTMC) have 47,XXY karyotype.

What is known already: Although the majority of non-mosaic KS patients is azoospermic, some patients with focal spermatogenesis (FS) can have children with artificial reproductive technologies. However, the genetic origin of FS is unknown. Independent of FS, dimorphism in sex chromatin has been reported amongst the seminiferous tubules of KS men. However, the karyotype of testis-specific cells in FS regions and other regions has not been clearly revealed so far.

The histone-3-lysine-27-tri-methylation (H3K27me3) modification is involved in suppression of the extra X chromosome, and its immunohistochemical staining allows the analysis of the X chromosome aneuploidy.

Study design, size, duration: Testicular biopsies were taken from 7 patients in whom spermatozoa were found by testicular sperm extraction (TESE). Muscle cells of female colon samples were used as positive control.

Participants/materials, setting, methods: After tissue processing and paraffine embedding, sections were cut at 5 µm. Immunohistochemical staining was performed with antibodies for H3K27me3 (inactive X chromosome), and MAGE-A4 (SPG), SOX9 (SC) and CYP17A1 (LC). PMTC was evaluated according to their position around the tubules and elongated shape. Inactive X (Xi) positive (Xi^+) and Xi negative (Xi^-) cells were counted and, Xi^+ cells were evaluated as having the 47,XXY karyotype; Xi^- cells were evaluated as having the 46,XY karyotype.

Main results and the role of chance: A total of 25 SPG^+ tubule sections were detected in 4 of 7 samples. Both SPG and SC were Xi^-, i.e. 46,XY karyotype, in all of these tubules. In some of the Sertoli cell only (SCO) tubules, SCs were Xi^+ (i.e. 47,XXY), while in others they were Xi^- (i.e. 46,XY). The rate of Xi^+ SC in SCO tubules containing Xi^+ SCs was 31.6%. Similarly, the Xi^+ ratio in muscle cells in the positive control was 31.0%. PTMCs surrounding tubules with SPG present, or ongoing FS were Xi^+ (i.e. 47,XXY). LCs were Xi^+ (i.e. 47,XXY) around all tubules. However, the percentage of Xi^+ PTMCs (21.4%) and LC (24.6%) was low compared to the female control (31.0%), suggesting mosaicism for these cells as well.

Limitations, reasons for caution: The fact that not all of the cell nuclei coincide with the section plane and the cells are in the mitotic stage limit the detection of Xi with H3K27me3. To overcome this limitation, X chromosome analysis could be performed by different techniques on intact cells isolated from fresh tissue.

Wider implications of the findings: FS occurs only in tubules with 46,XY SPGs and 46,XY SCs. Non-mosaic 47,XXY (diagnosed on blood cells) KS patients may present with testicular mosaicism, increasing their chances for sperm retrieval.

Trial registration number: Not applicable

O-140 studying the effect of mosaicism on the outcome of micro-TESE among Klinefelter syndrome patients

A. Al-Ahwani[1], R. Dawood[1], A. Fawzy[1], F. Elrefaey[2], H. AlAhwany[3]

[1]*Cairo University, Department of Andrology, Cairo, Egypt*
[2]*NCI, Department of Clinical Pathology, Cairo, Egypt*
[3]*Nile IVF Center, Department of Gynaecology, Cairo, Egypt*

Study question: Does mosaicism affect sperm retrieval rate in Klinefelter patients?

Summary answer: Patients with mosaic Klinefelter syndrome (KS) have a higher success rate of sperm retrieval than those with non-mosaic KS.

What is known already: Klinefelter syndrome is characterised by the presence of an extra X chromosome in male individuals leading to a 47XXY karyotype and rarely to 46XY/47XXY Mosaicism; it is the most common sex chromosomal aneuploidy and the most common genetic cause of Azoospermia (Kanakis GA et al., 2018 and Gravholt CH et al.,2018). It accounts for 3–4% of male infertility cases and 10–12% of men with Azoospermia (Winters SJ,2018).

Study design, size, duration: After approval of the ethical committee of the faculty of medicine at Cairo University, This prospective study was conducted where 70 men who complained of primary infertility and azoospermia and were diagnosed with Klinefelter Syndrome were recruited for this study between 1/11/2021 and 30/11/2022. Patients with previous testicular disease (torsion, trauma) or who had a history of undescended testes or received chemotherapy or radiotherapy were excluded.

Participants/materials, setting, methods: Seventy patients (n = 70) aged between 20 and 50 who fit the inclusion criteria were recruited and underwent micro_TESE. Semen analysis (Azoospermia), hormonal profile, scrotal colour doppler ultrasonography, Karyotyping and FISH for Y and X chromosomes were performed. Statistical analysis was conducted using SPSS 22nd edition.

Main results and the role of chance: Our study groups comprised 14 patients with mosaic KS and 56 with non-mosaic KS. The clinical characteristics were not significantly different statistically between the two groups. Micro_TESE was performed in all 70 patients; in 26 patients (37.1%), mature sperm were found in the wet preparation.

No statistically significant correlation was found between the presence of spermatozoa in the extraction specimen and age, serum follicle-stimulating hormone, serum testosterone, prolactin or oestradiol. The statistically significant predictor variable for sperm extraction was mosaicism, luteinising hormone, testicular volume and FISH. The sperm retrieval rate of the patients with mosaic and non-mosaic KS was 57.1% and 32.1%, respectively.

Limitations, reasons for caution: 1) Larger (n) number of patients was needed.

2) Despite our valuable findings, further studies should be performed to illuminate the relation between FISH for X and Y chromosomes and sperm retrieval rate success.

Wider implications of the findings: Klinefelter patients with mosaicism should be offered high sperm retrieval rate during IVF counselling.

[9]East Lancashire Hospitals NHS Trust, Department of Obstetrics and Gynaecology, Burnley, United Kingdom
[10]University of Nottingham, Nottingham Clinical Trials Unit, Nottingham, United Kingdom

Study question: Is a combination of parenteral methotrexate and oral gefitinib more effective than methotrexate alone in the treatment of tubal ectopic pregnancy?

Summary answer: In women with a tubal ectopic pregnancy, adding oral gefitinib to parental methotrexate does not offer clinical benefit over methotrexate and increases minor adverse reactions.

What is known already: Current treatment of tubal ectopic pregnancies is with methotrexate or surgery. Methotrexate treatment fails in ~30% of women and they require rescue surgery. At the time of the design of the trial, it had been shown in preclinical studies that tubal implantation sites express high levels of epidermal growth factor receptor (EGFR) and that gefitinib (an EGFR antagonist) augments methotrexate-induced regression of pregnancy-like tissue. There was also evidence from uncontrolled phase I and II trials that raised the possibility that combination methotrexate and gefitinib could be a more effective medical treatment than methotrexate alone to treat stable ectopic pregnancies.

Study design, size, duration: Between 2nd November 2016 and 6th October 2021, we performed a multicentre, randomised, double-blind, placebo-controlled trial across 50 UK hospitals. Eligible participants were women with a tubal ectopic pregnancy deemed suitable for medical management with methotrexate. Inclusion criteria were: aged 18-50 years; pre-treatment serum hCG level of 1000–5000 IU/L; and either a definite diagnosis of tubal ectopic pregnancy or a clinical judgement of 'probable' tubal ectopic pregnancy.

Participants/materials, setting, methods: Participants were administered a single dose of intramuscular methotrexate (50 mg/m^2) and randomised (1:1 ratio) to seven days of additional oral gefitinib (250mg daily) or placebo. The primary outcome, analysed by intention to treat, was surgical intervention to resolve the ectopic pregnancy. Secondary outcomes included time to resolution of ectopic pregnancy and serious adverse events.

Main results and the role of chance: 328 participants were allocated to methotrexate and gefitinib (n = 165) or methotrexate and placebo (n = 163). Three participants in the placebo group withdrew. Surgical intervention occurred in 30% (50/165) of the gefitinib group and in 29% (47/160) of the placebo group (adjusted risk ratio 1.15, 95% confidence interval [CI] 0.85-1.58; adjusted risk difference -0.01, 95% CI -0.10-0.09; p = 0.37). Without surgical intervention, median time to resolution was 28.0 days in the gefitinib group and 28.0 days in the placebo group (subdistribution hazard ratio 1.03, 95% CI 0.75-1.40). Serious adverse events occurred in 3% (5/165) of the gefitinib group and in 4% (6/162) of the placebo group. Diarrhoea and rash were more common in the gefitinib group.

Limitations, reasons for caution: Limitations of the trial include the fact that we only tested one dose regimen. It is possible gefitinib may be effective if a different protocol were used, such as a longer period of administration. Also, we did not carry out pharmacodynamic studies to determine optimal drug bioavailability.

Wider implications of the findings: Our results show that the addition of gefitinib to standard medical management with methotrexate to treat tubal ectopic pregnancy is not clinically effective as it does not reduce subsequent surgical intervention and is associated with higher rates of reported symptoms than placebo.

O-142 Surgical evacuation with adjuvant uterine artery embolization: a fertility preserving treatment for advanced live caesarean scar ectopic pregnancies

S. Nijjar[1], L. De Braud[1], D. Jurkovic[1]

[1]EGA Institute for Women's Health- University College London- London- United Kingdom, Faculty of Population Health Sciences- University College London- London- United Kingdom., London, United Kingdom

Study question: Can advanced caesarean scar ectopic pregnancies be managed safely surgically whilst preserving future fertility?

Summary answer: With the available support of uterine artery embolization, suction and curettage can be an effective treatment for live advanced caesarean scar ectopic pregnancies, avoiding hysterectomy.

What is known already: Caesarean scar ectopic pregnancies (CSEPs) are associated with significant maternal morbidity and termination of pregnancy is often offered to patients to protect their health and fertility. Treatment of early first trimester CSEPs is usually effective and safe, but the management of more advanced cases is more challenging, and hysterectomy has been considered the treatment of choice for second trimester CSEPs.

Study design, size, duration: This was a retrospective cohort study in a tertiary referral centre between 2008-2023. Of 371 women diagnosed with CSEP, 22 (6%) had live advanced CSEPs. 17/22 (77%) patients opted for surgery, whilst the remaining five opted to continue with their pregnancies. CSEP was defined by implantation of the pregnancy into a myometrial defect caused by dehiscence of a lower uterine segment caesarean scar. Advanced CSEP was defined as crown rump length (CRL) of ≥ 40mm.

Participants/materials, setting, methods: A preoperative ultrasound was performed in each patient. All women underwent surgical evacuation under ultrasound guidance and insertion of modified Shirodkar cervical suture as a primary haemostatic measure. Additional haemostatic measures included uterine artery embolization (UAE). Our primary outcome was the rate of blood transfusion. Secondary outcomes were estimated intraoperative blood loss (BL), UAE, and admission to intensive care unit (ICU) and fertility preservation. Descriptive statistics were used to describe these variables.

Main results and the role of chance: For the 17 cases included, median CRL was 54.1 mm (range 40.0 - 85.7) and median gestational sac diameter was 52.7mm (range 41.0 – 82.7). Median gestational age based on CRL was 12 + 2 weeks (range 10 + 6 weeks and 15 + 2 weeks).

Two (12%) women had a recurrent CSEP and 1 woman had a heterotropic pregnancy. On pre-operative ultrasound placental lacunae were recorded in 13 (76%) cases and colour Doppler score was ≥3 in 10 (59%) cases.

A Shirodkar cervical suture was used in all cases, as per our protocol. It was successful in achieving haemostasis by tamponade in 13/17 (76%) cases. In the remaining 4 (24%) tamponade failed to achieve a complete haemostasis and

UAE was required to control persistent arterial bleeding into the uterine cavity. Median BL at the time of surgery was 800 ml (range 250-2500) and 7/17 (41%) patients had a BL of > 1000 ml with 6/17 (35%) requiring blood transfusion. All four women who had UAE required admission to ICU. Three cases had a two-stage procedure with interval UAE to control the bleeding. All patients made a good postoperative recovery and no emergency hysterectomy was required. Three patients fell pregnant again and all pregnancies were normally sited.

Limitations, reasons for caution: Although this is the largest series of advanced CSEPs one limitation is its retrospective design and the relatively small number of cases. A second limitation is no women ≥ 16 weeks were included. Lastly, this study was conducted in a tertiary referral centre and results may not be widely replicable.

Wider implications of the findings: Surgical evacuation with a Shirodkar cervical suture and selective UAE is an effective treatment for advanced CSEPs and should be available to women who want to retain their fertility and avoid a hysterectomy. Pre-surgical planning and collaboration between gynaecologists and interventional radiologists is key in managing these high-risk women.

O-143 Biopsy-free profiling of the uterine immune system in patients with recurrent pregnancy loss and unexplained infertility

K. Vomstein[12], P. Egerup[2], A.M. Kolte[2], I. Behrendt-Møller[12], A. Dyhrberg Boje[2], M.L. Bertelsen[2], C. Eiken[2], M. Raupelyté Reiersen[2], B. Toth[3], N. La Cour Freiesleben[14], H.S. Nielsen[24]

[1]Fertility Clinic, Dep. of Obstetrics and Gynaecology- Copenhagen University Hospital Hvidovre, Hvidovre, Denmark
[2]The Recurrent Pregnancy Loss Unit, Copenhagen University Hospitals, Copenhagen, Denmark
[3]Department of Gynecological Endocrinology and Reproductive Medicine, Medical University of Innsbruck, Innsbruck, Austria
[4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Study question: What are the differences in menstrual blood lymphocytes between controls, patients with recurrent pregnancy loss (RPL) or with unexplained infertility (uINF)?

Summary answer: Compared with controls, RPL- and uINF patients had a different menstrual blood immune profile, including altered NK-subtypes indicating an altered cytotoxicity in these patients.

What is known already: T-cells, particularly regulatory T-cells, and uterine natural killer cells play a vital role as they are the main immunological regulators at the feto-maternal interface. However, an endometrial biopsy (EB) is required for the examination of these cells, necessitating an invasive and uncomfortable procedure. Moreover, the small tissue samples are mainly analyzed by immunohistochemistry, limiting the amount of analysable markers and ultimately results in controversial data. Menstrual blood (MB) has been used in proof-of-concept studies to analyse lymphocyte populations. So far, no study has investigated MB lymphocytes in a well-defined cohort of RPL- and uINF patients in comparison to healthy controls.

Study design, size, duration: In this prospective study, 46 healthy controls, 28 RPL patients and 11 uINF patients were included between 03/2021 and 02/2022. RPL was defined as ≥ 3 consecutive pregnancy losses. For being diagnosed with uINF, all standard-diagnostic procedures for infertility had to provide negative results in couples trying to conceive for >12 months.

Participants/materials, setting, methods: To establish the procedure, lymphocyte compositions in EB in 7 controls were compared with those in MB during 48h. The first 24h and the second 24h were collected separately. In all other RPL- and uINF-patients, as well as controls, peripheral blood (PB) and MB was collected. Density gradient centrifugation was performed to isolate PB and MB mononuclear cells. Cells were analyzed by flow cytometry focusing on the main lymphocyte populations and NK-cell subsets.

Main results and the role of chance: The first 24h of MB closely resembled the uterine lymphocyte composition in EB, with were $CD3^+$ T-cells and $CD56^+$ NK-cells being the predominant lymphocyte populations in EB and MB. We therefore based further analyses on the first 24h of menstrual shedding. In comparison to controls, RPL-patients showed significantly higher MB-$CD56^+$-NK-cell numbers (mean ± SD: 31.13 ± 7.52 vs. 36.73 ± 5.4; p = 0.002). Furthermore, MB-$CD56^{dim}CD16^{bright}$ NK-cells within the $CD56^+$-NK-cell population were decreased in individuals with RPL and uINF compared to controls (mean ± SD: 20.4 ± 11.53;16.34 ± 14.65;15.7 ± 5.91; Ctrl vs. RPL p = 0.011; Ctrl vs. uINF p = 0.02). Further, compared to controls and RPL patients, uINF patients had lower $CD3^+$ T-cell counts (mean ± SD Ctrl. vs. uINF: 47.93 ± 11.11 vs. 38.81 ± 5.04, p = 0.013), with decreased $CD4^+$ (mean ± SD Ctrl. vs. uINF: 25.78 ± 7.91 vs. 15.66 ± 4.88, p = 0.001) and $CD8^+$ T-cells (mean ± SD Ctrl. vs. uINF: 15.32 ± 4.14 vs. 8.43 ± 2.85, p < 0.001). Interestingly, uINF-patients showed higher $CD25^{high}CD127^{dim/neg}$ regulatory T-cell counts than controls (mean ± SD Ctrl. vs. uINF: 1.34 ± 0.49 vs. 1.84 ± 0.51, p = 0.009). The cytotoxicity receptors NKp46 and NKG2D were more present in uINF and RPL patients. Furthermore, RPL and uINF patients had significantly higher peripheral $CD56^+$-NK-cell counts as compared to controls (mean ± SD: 8.4 ± 3.5;11.42 ± 4.05;12.86 ± 4.29; Ctrl vs. RPL p = 0.021; Ctrl vs. uINF p = 0.009).

Limitations, reasons for caution: The small sample size of our study limits our ability to extrapolate the findings to other populations, as well as perform further subgroup analyses in controls, RPL and uINF. Future research must concentrate on NK cell subpopulations in larger cohorts, potentially in a multi-center setting.

Wider implications of the findings: Strengths of this study include well phenotyped participants and that the immunological milieu of the endometrium is directly compared for EB and MB. In future studies, this non-invasive analysis might enable to identify and monitor patients who could profit from (immunomodulatory) medications, and thereby improve live birth rates.

O-144 Critical assessment of possible clinical benefits of culturing human embryos until day 7

A. Abdala[1], I. Elkhatib[1], A. Bayram[1], A. El-Damen[1], L. Melado[2], B. Lawrenz[2], E. Kalafat[3], H.M. Fatemi[2], D. Nogueira[1]

[1]ART Fertility Clinics, IVF Laboratory, Abu Dhabi, United Arab Emirates
[2]ART Fertility Clinics, Gynecology, Abu Dhabi, United Arab Emirates
[3]Division of Reproductive Endocrinology and Infertility- Koç University School of Medicine, Department of Obstetrics and Gynecology, Istanbul, Turkey

Study question: Is there any benefit of extending culture until day (D) 7 to increase euploid blastocysts yield and clinical outcomes in a PGT-Aneuploidy analysis (PGT-A) program?

Summary answer: Extended culture until D7 increases euploid blastocysts yield and cumulative live birth. Highest benefit was observed in patients aged ≤41 with ≤2 D5/D6 blastocysts biopsied.

What is known already: It is well-known that female age is the strongest predictive factor of embryo aneuploidy and has been associated with delayed blastocyst development in vitro. Culturing embryos until D7 might increase biopsied blastocyst yields and euploidy outcomes among women undergoing ART as already been published. However, extended culture until D7 increases IVF workload and implies extra cost. It is unclear whether the practice is justified when a certain number of blastocysts have already been biopsied on D5/D6. Therefore, the additive value of extended culture until D7 needs further evaluation. Studies published in the literature have small sample sizes and are controversial.

Study design, size, duration: This single center observational study included 30,941 blastocysts from 6,976 consecutive IVF/ICSI PGT-A fresh autologous cycles performed between 2017 and 2022. Patients who underwent PGT-A by Next Generation Sequencing (NGS) were considered for the analysis. Only blastocysts graded ≥BL3CC (Gardner) that underwent TE biopsy on D5, D6 or D7 were included. Data were stratified by age categories (<37, 37-41 and >41) and on number of biopsied blastocysts performed on D5 and/or D6 of embryo culture.

Participants/materials, setting, methods: The additive value of extended embryo culture was assessed in terms of absolute numbers (percentage of D7 euploid blastocysts obtained) and theoretical benefit to cumulative live birth rate (having at least 1 live birth by using all available euploid blastocysts) as calculated by binomial density function. Results was assessed between female age strata (<37, 37-41, >41) and number of embryos biopsied in D5/D6 (No biopsy, ≤2, 3-4, 5-6 or ≥ 6 biopsied).

Main results and the role of chance: A total of 18,478 blastocysts were biopsied on D5 (38.5%), D6 (55.2%) or D7(6.3%). Euploidy rate decreased significantly for blastocysts biopsied on D5, D6 and D7 (55.6%, 39.7% and 27.1%, $P < 0.001$, respectively). When stratifying patients by age, euploidy rates were consistently higher for D5 biopsied blastocysts compared to D6 and D7 (<37: 61.1%, 50.0% and 38.5%, $P < 0.001$; 37-41: 39.0%, 27.8% and 20.1%, $P < 0.001$; >41: 18.5%, 9.0% and 3.9%, $P < 0.001$, for D5, D6 and D7, respectively). The chances of obtaining at least one euploid D7 blastocyst was higher among patients <37 and 37–41 years compared to > 41 years (7.2% and 4.4% vs. 0.6%, $P < 0.001$). Among women <37, a > 25% increase in cumulative live birth rate (theoretical) was detected in 10.1% with no biopsy on D5/D6, 2.5% with 1-2 blastocysts biopsied on D5/D6 and only 0.3% with ≥3 blastocysts biopsied on D5/D6 ($P < 0.001$). In older women (37-41), a > 25% increase in cumulative live birth rate (theoretical) was found in 5.6% with no biopsy on D5/D6, 2.5% with 1-2 blastocysts biopsied on D5/D6, and only 0.4% with ≥3 blastocysts biopsied on D5/D6 ($P < 0.001$). Women >41 years rarely benefited from extended culture util D7 (<1%) regardless of the number of blastocysts biopsied on D5/D6.

Limitations, reasons for caution: The study was based on a retrospective analysis data and results were calculated on a theoretical cumulative live birth. While this study provides one of the largest number of blastocysts analyzed in PGT-A and "freeze all" strategy, results should not be extrapolated to other populations or different ART routine practices.

Wider implications of the findings: Usable blastocysts (6.3%) and euploidy rates (27.1%) are significantly lower with D7 blastocysts compared to D5/D6 blastocysts. Patients aged >41 do not benefit from extended embryo culture to D7 (<1%). Culturing blastocysts for 7 days should be mainly decided based on the number of blastocysts biopsied on D5 or D6.

O-145 From mathematical modeling to real-life clinical data: live birth rates up until the tenth blastocyst transfer without PGT-A

S. Mackens[1], S. Loreti[1,2], E. Goyens[1], M. De Vos[1], H. Tournaye[1], E. Somigliana[2], N. De Munck[1], C. Blockeel[1]

[1]*UZ Brussel, Centre for Reproductive Medicine - Brussels IVF, Jette- Brussels, Belgium*
[2]*University degli Studi di Milano, Clinical Sciences and Community Health, Milan, Italy*

Study question: What is the cumulative live birth rate (CLBR) from the first until the tenth consecutive blastocyst transfer, across all age-groups, if no PGT-A is applied?

Summary answer: Our clinical data confirm existing mathematical models: without PGT-A, a CLBR of 70.0% after three, 88.9% after seven and 95.9% after ten transfers was observed.

What is known already: The rate of 'true' repeated implantation failure (RIF) from endometrial origin is an important topic of debate in our scientific community. Its existence was challenged with the reporting of CLBRs >90% after three consecutive euploid blastocyst transfers. These findings are not directly applicable when PGT-A is not routinely performed. Mathematical models have been developed to tackle this issue by taking into account (1) the anticipated euploidy rate based on the oocyte's age and (2) the probability of an euploid embryo to implant. So far, no actual patient data have confirmed the validity of this model.

Study design, size, duration: This is a single-center, retrospective, observational cohort study including 4320 unique women who underwent up to ten consecutive blastocyst transfers between 2010 and 2020. All age categories were included, as well as fresh/frozen and single/double embryo transfers. Patients using donor oocytes, PGT or cleavage stage embryo transfers were excluded or led to drop-out in the study.

Participants/materials, setting, methods: Patient characteristics were retrieved and cumulative outcomes were analyzed. A Kaplan-Meier curve was plotted for CLBR. For each transfer cycle the live birth rate (LBR), double embryo transfer rate (DET) and multiple pregnancy rate were calculated.

Main results and the role of chance: The mean age of the patients included in the study was 31.8 (± 4.5) years at the time of the first ovarian stimulation. The mean body mass index was 23.7 (± 4.3) kg/m^2 and mean basal FSH 6.8 (± 2.3) IU/L. The mean number of stimulations per patient was 1.21 (± 0.5) and a total mean number of 4.6 (± 3.2) blastocysts were obtained per patient. The mean time to the pregnancy leading to live birth was less than one year (0.3 ± 0.7).

We observed the highest LBR (46.3%, 2002/4320) after the first blastocyst transfer followed by 35.4% (593/1672), 32.3% (275/851), 32.2% (147/456), 32.8% (78/238), 21.3% (26/122), 23.9% (17/71), 25.6% (10/39), 31.8% (7/22), 18.2% (2/11) for the second until the 10th transfer, respectively.

The Kaplan-Meier curve showed CLBRs to mount from 70.0% after the third, up to 88.9% after the seventh and 95.9% after the tenth blastocyst transfer.

We noticed a steady increase in DET rate from only 6.4% in the first up to > 27% as of the fourth and >44% as of the seventh transfer with acccompanied multiple pregnancy rates of 1.3% over 10.9% and 11.8%, respectively.

Limitations, reasons for caution: The main limitation is the study's retrospective nature. As our center performs cleavage stage and blastocyst transfer, the included population is a good prognosis one as embryology allowed to perform extended culture. Nevertheless, to investigate RIF due to endometrial causes, this could also be seen as an asset.

Wider implications of the findings: These patient data confirm mathematical models and further question the prevalence of insurmountable, endometrial origin RIF. Preserved LBRs (even in higher cycle ranks) and a CLBR >95% provide hope and reassurance to couples with failed embryo transfers and encourage them to continue treatment if blastocysts are available.

O-146 Oocyte donation does not increase live birth rates in young women suffering from recurrent pregnancy loss

I. Miguel-Escalada[1], A. Almansa-Ordoñez[2], J. Santaló[3], A. Blázquez[4], R. Vassena[2], G. Tiscornia[2], M. Popovic[2], A. Rodriguez[5]

[1]*Clinica EUGIN, Research and Development, Barcelona, Spain*

[3]*Universitat Autònoma de Barcelona, Departament de Biologia Cel·lular- Fisiología i Inmunología, Barcelona, Spain*
[4]*Clinica EUGIN, Medical, Barcelona, Spain*
[5]*EUGIN group, Corporate Medical, Barcelona, Spain*

Study question: Does oocyte donation improve reproductive outcomes in recurrent pregnancy loss (RPL) patients?

Summary answer: Oocyte donation increases live birth and reduces miscarriage rates in RPL women older than 35, but it does not improve reproductive outcomes in younger patients.

What is known already: Recurrent pregnancy loss (RPL) is defined as 2 or more pregnancy losses prior to 20-24 weeks of gestation and has an incidence of approximately 1 to 2% in couples trying to conceive. Known risk factors for RPL are embryo aneuploidy, advanced maternal age (AMA), previous miscarriages, uterine abnormalities, parental chromosomal abnormalities, antiphospholipid syndrome, endocrine factors, such as thyroid function or obesity, and thrombophilia. However, 50-70% of patients suffering from RPL do not present any known risk factor, making the management of idiopathic RPL patients particularly challenging for ART clinicians.

Study design, size, duration: This is a cohort retrospective study involving 2 centers. Charts from 18,273 women undergoing IVF treatment between

2011 and 2020 were reviewed. A total of 912 patients (5%) met the definition of RPL and were classified into study groups based on their age and oocyte origin: ≤35 years old receiving oocyte donation (n = 39) or using their own oocytes (n = 35), and AMA women using donor eggs (n = 716) or their own (n = 122).

Participants/materials, setting, methods: Demographic variables analysed included known risk factors, number of transferred embryos, day of embryo transfer (3 vs 5) and sperm origin (partner/donor). Differences in biochemical, clinical, ongoing pregnancy, miscarriage and live birth rates were assessed by Pearson's Chi-squared or Fisher's exact test. P-values <0.05 were considered significant.

Main results and the role of chance: RPL patients had 2.77 ± 1.27 pregnancy losses overall (2.76 ± 1.37 in women ≤35 and 2.77 ± 1.26 in patients >35). Most RPL patients (91.9%) were of AMA. Other RPL-associated risk factors, including uterine malformations, previous pregnancy losses, chromosomal abnormalities and thrombophilia were identified in 207/912 patients (22.7%). Interestingly, these were more frequent in patients <35 (37.8% vs 21%, p = 0.001). Young RPL women presented higher rates of karyotype abnormalities than older patients (17.6% vs 3.8%, $p < 1x10^{-04}$), while showing a similar incidence of uterine abnormalities (14.9% vs 12.9%, p > 0.63) and thrombophilia (4.1% vs 4.7%, p > 0.81).

RPL patients >35 preferentially underwent oocyte donation (85.4% vs 52.7%, $p < 1x10^{-04}$), which led to significantly higher biochemical (52.5% vs 17.1%, $p < 1x10^{-04}$), clinical (42.4% vs. 8.5% $p < 1x10^{-04}$), ongoing pregnancy (37.9% vs 5.1%, $p < 1x10^{-04}$), live birth (32% vs 4%, $p < 1x10^{-04}$) and lower miscarriage rates (10.5% vs 40%, p = 0.0186) than in autologous cycles. In contrast, RPL patients <35 had similar reproductive outcomes: biochemical (41% vs. 52.9), clinical (28.2% vs. 37.1%), ongoing pregnancy (25.6% vs 29.4%), live birth (25.6% vs 26.4%) and miscarriage rates (9% vs 23%), regardless of oocyte origin (donated vs own, p > 0.05 for all cases). Importantly, this was also true for a small subgroup of idiopathic young RPL patients (n = 13).

Limitations, reasons for caution: The main limitation of this study is its retrospective nature, which does not allow for full elucidation of all potential confounders. The number of young RPL patients undergoing oocyte donation may be too low to draw significant conclusions.

Wider implications of the findings: RPL can be resolved in AMA patients by using donor oocytes, which points to key roles of oocyte quality and aneuploidy underlying RPL aetiology. However, RPL is not ameliorated by oocyte donation in young women, suggesting an endometrial/systemic origin and highlighting the need to further study mechanisms driving this disorder.

O-147 Factors influencing ICSI outcome after sperm retrieval in nonobstructive azoospermia patients with different types of etiologies: a retrospective study of 1157 patients

L. Zhang[1], T. Wenhao[2], L. Ping[1], H. Kai[2]

[1]*Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China*
[2]*Peking University Third Hospital, Department of Urology, Beijing, China*

Study question: What are predictors of fertilization, clinical pregnancy, miscarriage and livebirth delivery outcomes after microdissection testicular sperm extraction (mTESE)-ICSI in NOA patients with different etiologies?

Summary answer: Predictors for ICSI outcome were different in patients with various etiologies and type of NOA are associated with ICSI outcome in these patients.

What is known already: NOA patients due to spermatogenic dysfunction, accounting for about 60 percent of the total azoospermia cases, may have opportunities to be fathers with their own biological children by mTESE combined with ICSI. For them, there were some of predictive factors for ICSI outcome including sperm motility, sperm morphology, testis volume and levels of reproductive hormone including follicle stimulating hormone (FSH), luteinizing hormone (LH) and testosterone (T), while the predictive factors of ICSI outcome remains underappreciated, especially about the relationship between ICSI outcome and male factors after reviewing the large scale clinical data.

Study design, size, duration: This retrospective study involved 1157 NOA patients with treated 1534 complete ICSI cycles at the Reproductive Medical Centre of Peking University Third Hospital from March 2012 to October 2021.

Participants/materials, setting, methods: 1534 ICSI cycles included 558, 359, 243, 155, 128, 56 and 35 cycles performed in males with idiopathic NOA (iNOA), Klinefelter syndrome (KS), AZFc microdeletions, cryptorchidism, a history of mumps orchitis, cryptozoospermia and with other causes separately. Primary outcome was livebirth delivery per ICSI cycle (LBR) and secondary outcomes were clinical pregnancy rate per ICSI cycle (PR) and fertilization rate (FR). Multi-variable logistic and linear regression was used to analyze ICSI outcome.

Main results and the role of chance: Overall LBR, PR and FR were 37.35%, 44.98%, 49.34% separately. Patients with mumps orchitis showed the highest LBR, PR and FR of 53.13%, 60.94% and 59.52% respectively, and AZFc-deleted patients displayed the lowest LBR, PR and FR of 25.93%, 30.04% and 32.87% separately. Lower female age (0.947 [0.904;0.993], p = 0.024), more transferred embryos (1.345 [1.225;1.477], p<0.001), higher AFC (1.033[1.011;1.056], p = 0.003) were related with higher LBR, and higher male BMI (0.974[0.950; 0.999], p = 0.046) and lower AFC (1.057[1.034; 1.080], p<0.001) were related with lower PR. Comparing outcome of mumps orchitis group, patients with cryptorchidism were associate with lower LBR(0.467[0.281; 0.778], p = 0.003), PR (0.440[0.268;0.721], p = 0.001) and FR(-0.169 [-0.226; -0.11], p<0.001) separately. AZFc-deleted patients had a relationship with lower LBR (0.426[0.260; 0.697], p = 0.001), (0.273[0.170; 0.437], p<0.001) and FR (-0.282 [-0.336; -0.228], p<0.001) respectively. KS patients were related with lower LBR (0.455[0.288; 0.720], p = 0.001), PR (0.477 [0.306; 0.745], p = 0.001) and FR (-0.073 [-0.126; -0.020], p = 0.007) separately. iNOA patients were associated with lower PR (0.616 [0.409; 0.928], p = 0.020) and FR (-0.076 [-0.124; -0.029], p = 0.002) respectively. Furthermore, patients with cryptozoospermia were related with lower FR (-0.141 [-0.220; -0.061], p = 0.001).

Limitations, reasons for caution: Sperm characteristics maybe predictors for ICSI outcome which is a potential selection bias. Pituitary prolactin and Anti-Müllerian hormone weren't included as covariates due to limited information in our database. We couldn't verify the conclusion in more population from multicenter despite the current study with the large sample size so far.

Wider implications of the findings: Our results provide valuable information for NOA patients who want to counsel surgeons about their ICSI outcome to help patients and surgeons to perform a shared decision-making for optimal therapy methods, especially for AZFc-deleted patients with worse ICSI outcome who may consider donor semen to get better ICSI outcome.

O-148 Cumulative embryotoxic effect of IVF plastic devices used sequentially in routine clinical practice could slow the embryo development and delay blastulation

L. Delaroche[1], L. Besnard[1], M. Acacio[2], E. Mestres[2], N. Costa-Borges[2]

[1]Ramsay Santé, Biogroup - IVF Center - Parly 2 Private Hospital, Le Chesnay, France
[2]Embryotools, Embryotools, Barcelona, Spain

Study question: Is there an embryotoxic cumulative effect resulting from IVF plastic consumables (PC) when used sequentially under clinical routine practice?

Summary answer: Reduced blastulation rates and slow development were detected in some associations of PC evaluated by the Mouse Embryo Assay (MEA) suggesting possible cumulative embryotoxicity.

What is known already: Recommendations from European (ESHRE) and American (ASRM) societies regarding the use of IVF PC suggest that they should undergo appropriate quality control tests to detect the possible presence of embryotoxins. The main test used by manufacturers to exclude any embryotoxicity is the MEA. This assay is currently performed individually on each PC so that a certificate of conformity is delivered for each product/lot. However, several PC are used during a single IVF cycle, potentially creating an embryotoxic cumulative effect. To our knowledge, the cumulative toxicity of several PC used sequentially on gametes and embryos has not been studied so far.

Study design, size, duration: The objective of this prospective study was to determine if there is cumulative embryotoxicity when several PC are used together under clinical routine conditions. Ten associations, each containing 13 to 31 PC, were designed, and assessed for embryotoxicity using a MEA methodology. The tested combinations replicated the different steps used in an IVF cycle, including sperm collection and selection, oocyte pick-up, fertilization, embryo culture, embryo transfer, vitrification and thawing and sperm freezing.

Participants/materials, setting, methods: A defined volume of culture media was used to extract the toxicity of several PC used in every association in triplicate. The MEA tests were performed on each medium extraction with 21 one-cell stage fresh mouse embryos. Blastocyst formation rates after 96 and 120h of culture (Day 5/6), blastocyst good quality rates and hatched blastocyst rates were compared between the tested and control groups. The total cell number per blastocyst was also evaluated.

Main results and the role of chance: No toxicity was detected in the first two associations comprised of 22 and 23 PC, which mimicked the collection (either in sperm cups or in spermicide-free condoms) and processing of sperm samples.

However, the third association comprised of 32 plastic devices replicating the sperm collection in sperm cups, processing, and freezing in high security straws, showed toxicity as the mean blastulation rate at day 5 was reduced to 20.6% compared to 95.6% in the control group ($p < 0.05$). Surprisingly, the mean blastulation rates observed at day 6 was 55.6% versus 100.0% in the control group ($p < 0.05$). The blastocysts obtained at day 6 showed a mean number of cells ($n = 112.5$) significantly reduced in comparison with the control group ($n = 167.9$) ($p < 0.05$), suggesting a sublethal presence of toxins which slowed embryo development down and delayed blastulation.

More experiments involving toxicity assessment in other associations of PC are currently undergoing and will be presented at the conference.

Limitations, reasons for caution: Sensitivity could vary depending on the methodologies used for toxicity extraction and MEA. The main cause, if any, of the detected toxicity will need to be pinpointed by analyzing each element of the affected associations individually.

Wider implications of the findings: Also, professionals should rationalize and minimize the number of plastic consumables used during the IVF procedures to reduce the potential accumulation of toxicity in the embryo culture system.

O-149 Endometrial thickness as a predictor of live birth and perinatal outcomes following oocyte donation

S. Santos-Ribeiro[12], F. Rafael[34], F. Fernandes[2], J. Martínez[5], A.R. Neves[1], E. Labarta[6], N. Garrido[5], S. Nunes[1], J.A. Garcia-Velasco[7], S. Reis-Soares[1]

[5]IVI-RMA, IVI Foundation, Valencia, Spain
[6]IVI-RMA Valencia, Reproductive Medicine, Valencia, Spain
[7]IVI-RMA Madrid, Reproductive Medicine, Madrid, Spain

Study question: Does endometrial thickness (EMT) predict the occurrence of live birth following oocyte donation?

Summary answer: Our study found that EMT is predictive of live birth in oocyte donation.

What is known already: EMT is a widely used surrogate marker of endometrial receptivity and is believed to be associated with in vitro fertilization pregnancy outcomes. However, the evidence thus far is mixed, with many studies (and even meta-analyses) suggesting that EMT may have little/no predictive value. One potential reason for the heterogeneity in results may be that most studies assessed mostly fresh autologous embryo transfers, without accounting for embryo quality nor the effect exogenous ovarian stimulation may have on endometrial receptivity and subsequent pregnancy/perinatal outcomes. Moreover, most subcategorized EMT to facilitate interpretation, which may have inadvertently introduced bias to the analyses.

Study design, size, duration: This retrospective, multicentre, cohort study analyzed all single blastocyst embryo transfers following oocyte donation from 2010-2019 subdivided into regular intervals of EMT (<7.0 mm, 7.0-8.9 mm, 9.0-10.9 mm, ≥11.0 mm). EMT was also evaluated as a continuous variable, comparing the best-fitting fractional polynomial against the linear function, to minimize bias due to residual confounding that may occur following the categorization of continuous variables. Confounder adjustment was performed using multivariable generalized estimating equations regression analysis.

Participants/materials, setting, methods: The oocyte donation model was chosen to minimize the influence of potential confounding factors such as poor embryo quality and the effect of ovarian stimulation on endometrial receptivity. The main objective of the study was to compare live birth rates (LBR). Our secondary outcomes included other surrogate pregnancy (hCG-positive pregnancy, clinical pregnancy, and miscarriage rates) and perinatal (gestational age at birth, preterm birth under 37 weeks, birthweight z-score, small and large for gestational age) outcomes.

Main results and the role of chance: In total, 33915 embryo transfers were analyzed. Confounder variables included were female donor and recipient age, recipient BMI, female factor infertility, male factor infertility, number of mature oocytes donated, oocyte status (fresh versus vitrified), sperm source (partner or donor), embryo status (fresh versus vitrified), embryo quality, endometrial preparation (natural or artificial cycle) and year of transfer. When compared to the reference EMT of 9.0-11.0 mm, EMT <7.0 mm was associated with lower hCG positive pregnancy rates (51.3% vs 57.6%; aOR 0.82 CI 0.75-0.89), lower clinical pregnancy (41.9% vs 49.1%; aOR 0.79 CI 0.73-0.86), higher miscarriage rates per hCG positive pregnancy (37.5% vs 31.4%; aOR 1.31 CI 1.16-1.47) and lower LBRs per transfer (32.1% vs 39.5%; aOR 0.76 CI 0.69-0.83). Regarding perinatal outcomes, we found significantly higher preterm delivery rates following an EMT <7.0 mm (14.1% vs 9.9%; aOR 1.54 CI 1.21-1.96) and higher large for gestational age rates associated with EMT ≥11.0 mm (16.4% vs 12.2%; aOR 1.40 CI 1.07-1.83). The fractional polynomial analysis revealed that the subcategorization of EMT caused clinically-relevant residual confounding. Specifically, LBRs assumed an approximate bell-shaped relationship with EMT, with LBR rates decreasing for both thinner EMTs (<7 mm subgroup) and thicker EMTs (≥11.0 mm subgroup).

Limitations, reasons for caution: The retrospective nature of the study and the inherent risk of bias related to unmeasured confounding may have impacted the results. Another potential limitation is the lack of perinatal outcome data due to loss of follow-up, which should be considered when interpreting these results.

Wider implications of the findings: Our results support the use of EMT as a predictor of live birth and as a marker of endometrial receptivity and competence. Moreover, it stresses the potential danger of subcategorizing all EMT <7.0 mm and >11.0 mm as equivalent, as the study found that these subgroups have varying LBR.

O-150 Birth defects reporting and the use of oral dydrogesterone in assisted reproductive technology : a global pharmacovigilance study

A. Henry[1,2], P. Santulli[3], M. Bourdon[3], J.M. Treluyer[1,2], L. Chouchana[1,2]

[1]Assistance Publique–Hôpitaux de Paris AP–HP- Hôpital universitaire Paris Centre HUPC-Université Paris Cité- Centre Hospitalier Universitaire CHU Cochin, Regional Center of Pharmacovigilance- Department of perinatal- pediatric and adult Pharmacology, Pa
[2]Université Paris Cité, EA7323- Pharmacology and Therapeutic Evaluation in children and pregnant women, Paris, France
[3]Assistance Publique–Hôpitaux de Paris AP–HP- Hôpital universitaire Paris Centre HUPC-Université Paris Cité- Centre Hospitalier Universitaire CHU Cochin, Department of Gynaecology Obstetrics and Reproductive Medecine, Paris, France

Study question: Is dydrogesterone exposure during early pregnancy associated with the reporting of birth defects ?

Summary answer: We observed an increased reporting of birth defects, such as congenital heart defects and hypospadias, with dydrogesterone, especially compared to progesterone use.

What is known already: In assisted reproductive technology (ART), intravaginal administration of progesterone is the standard of care to overcome luteal phase progesterone deficiency induced by ovarian stimulation. In the recent years, the Lotus I and Lotus II randomized controlled clinical trials, demonstrated that oral dydrogesterone, a synthetic progesterone derivative, was non-inferior for pregnancy rate at 12 weeks of gestation and could be an alternative to micronized vaginal progesterone (MVP). Safety profiles in both mother and child were similar. However, concerns have been raised recently regarding an association between dydrogesterone usage during early pregnancy and congenital heart disease in the offspring.

Study design, size, duration: We performed a case-non case study, similar in the concept to case-control study, using the international pharmacovigilance database, VigiBase. Study cohort consisted in spontaneous reports regarding pregnant women identified using the ad-hoc standardized query (SMQ "Pregnancy and neonatal topics"). Birth defect cases were reports containing a term related to "congenital, familial and genetic disorders" System Organ Classes (SOCs) (excluding genetic, infectious and metabolic abnormalities). Non-cases were reports of any other adverse drug reaction.

Participants/materials, setting, methods: Through a case–non case study conducted since database inception to 12/31/2021, we first compared the reporting of birth defects with dydrogesterone to that of any other drug, then to any other drug used for ART. Secondly, we performed a comparison on the reporting of birth defects for dydrogesterone with progesterone. Results are presented as reporting odds ratio (ROR) and their 95% confidence interval (95%CI). For each comparison, two sensitivity analyses were performed.

Main results and the role of chance: Among 29,120,563 individual case safety reports, 50,653 were related to the use of drugs for ART. Of these, 375 were cases of birth defects, including 60 (16%) with dydrogesterone. Dydrogesterone cases were mostly reported from Europe (73%) by physicians (82%). No other teratogenic drug was suspected in the onset of birth defect for dydrogesterone. 44 cases out of 60 (73.3%) were compatible with major birth defect (MBD) cases according to EUROCAT classification. These cases contained a total of 55 MBD, consisting mainly in genital defects such as hypospadias (n = 18, 32.7%), congenital heart defects (n = 15, 27.3%) limb defects (n = 10, 18.2%) and digestive system defects (n = 6, 10.9%). In the primary analysis, a significant disproportionate reporting of birth defects was found with dydrogesterone when compared to any other drug (ROR 5.4, 95%CI [3.9-7.6]) and to any other ART agent (ROR 5.9, 95%CI [4.2-8.4]). In the head-to-head comparison to progesterone, we found an increased reporting of birth defect with dydrogesterone (ROR 5.4, 95%CI [3.7-7.9]).These results were confirmed in both sensitivity analyses.

Limitations, reasons for caution: First, under-reporting, being inherent to pharmacovigilance systems, impedes the measurement of the incidence of adverse drug reaction and can limit the sensitivity of signal detection. Second, drug causality, not being the same for all cases, is challenging for such events and requires further assessment. However, sensitivity analyses showed consistent results.

Wider implications of the findings: Physicians should be aware of this potential risk and caution should be used when prescribing dydrogesterone for luteal phase support. Further data are needed to confirm that safety signal.

O-151 Intrahepatic cholestasis of pregnancy and relevant neonatal outcomes in IVF versus spontaneous conception: a prediction nomogram-based study

J. Yang[1], X. Zhang[1], G. Huang[1], H. Ye[1]

[1]chongqing health center for women and children, Chongqing Reproductive and Genetics Institute, Chongqing, China

Study question: Does the incidence of intrahepatic cholestasis of pregnancy (ICP) differ in spontaneous conception(SC) versus in vitro fertilization (IVF) conception?

Summary answer: We observed that the ICP rate was higher in IVF than in SC, and first built a prediction nomogram to find the predictors of ICP.

What is known already: There are limited clinical studies comparing intrahepatic cholestasis of pregnancy(ICP) and neonatal outcomes in puerperae who spontaneously conceived and those who conceived via assisted reproductive technology. Several studies comparing the maternal, laboratory, and perinatal characteristics of in-vitro fertilization(IVF) and spontaneous pregnancies concerning ICP show that IVF treatment has an increased risk of ICP in singleton and multiple deliveries. However, given that it is difficult to collect big data, most research on IVF patients with ICP involve small sample size or case reports.

Study design, size, duration: This was a retrospective real-world data study that linked the information from puerperae and neonates. We included 4,467 puerperae who conceived via ART, and 28,336 puerperae who conceived spontaneously.

Participants/materials, setting, methods: Cochran–Mantel–Haenszel (CMH) analysis and a general linear model (GLM) were used to control bias. We compared the related serum-derived indicators and neonatal outcomes of ICP patients with in vitro fertilization (IVF) and SC. Multivariate logistic regression analysis, a forest plot, and nomogram were used to assess impact factors and risk prediction.

Main results and the role of chance: Logistic analysis adjusted for confounders revealed significant differences in the ICP rate of singleton delivery (4.24% vs. 3.41%, adjusted OR = 1.26 [95% confidence interval (CI) 1.03–1.53], *P*=0.025) and in groups with total bile acids(TBA) ≥40 and <100 μmol/L (14.77% vs. 10.39%, aOR=1.31[95% CI 1.06–1.63], *P*=0.023) between IVF and SC. When we divided newborns into singleton and twins delivery, the GLM revealed a higher rate with Apgar score <7 (13.44% vs. 3.87%; aOR=3.85 [95% CI: 2.07–7.17], *P* <0.001) and fetal distress for IVF in comparison with SC (19.32% vs. 5.55%; OR = 3.48 [95%CI: 2.39–6.95], *P* <0.001) in the singleton group. In multivariate logistic regression analysis, five factors were independent predictors of ICP: body mass index (BMI) (aOR=1.75 [95% CI 1.03–2.13], *P*=0.036), number of embryo transferred (ET) (single ET vs. double ET: aOR=4.82 [95% CI 3.83–6.05], *P*<0.001), E_2 level on the ET day (aOR=2.79 [95% CI 1.79–4.05], *P*=0.011),

fresh ET which compared with frozen ET (FET) (aOR=1.40 [95% CI 1.09–1.80], P=0.008), and severe ovarian hyperstimulation syndrome which compared with non-OHSS (aOR=3.97 [95% CI 1.79–8.80], P<0.001). These predictive factors in the logistic regression model were integrated into the nomogram (C-index=0.735 [95% CI, 0.702–0.764]); for each patient, higher total points indicated a higher risk of ICP.

Limitations, reasons for caution: The limitations of this study include its retrospective nature, and the balance in baseline characteristics between IVF and SC measured using statistical methods.

Wider implications of the findings: Our results provide evidence for the incidence of ICP between spontaneously conceived and those who conceived via IVF, and found predictors of ICP in IVF treatment. It could assist physicians in making clinical decisions avoiding risk factors during IVF, and taking preventive countermeasures for patients.

O-152 Benign epithelial ovarian tumors following use of fertility drugs: a register-based cohort study from Denmark

M. Gottschau[1], K. Frederiksen[2], C. Lima, Brown Frandsen[1], M. Hargreave[3], B. Nøhr[1], S. K. Kjær[3], A. Jensen[1]

[1]*Danish Cancer Society Research Center, Lifestyle- Reproduction and Cancer, Copenhagen, Denmark*
[2]*Danish Cancer Society Research Center, Statistics and Data Analysis, Copenhagen, Denmark*
[3]*Danish Cancer Society Research Center, Virus- Lifestyle and Genes, Copenhagen, Denmark*

Study question: Is use of fertility drugs associated with an increased risk of benign epithelial ovarian tumors among women with infertility?

Summary answer: Among women with infertility, use of fertility drugs is not associated with an increased risk of benign epithelial ovarian tumors.

What is known already: Benign epithelial ovarian tumors are the most common neoplasms in the ovaries. These benign tumors share some of the same risk factors, which are associated with ovarian cancer. The general understanding of the pathogenesis and etiology of ovarian cancer is sparse; therefore, knowledge on factors influencing development of benign epithelial ovarian tumors—and hence likely ovarian cancer—is warranted. Previous studies on the association between fertility treatment and ovarian cancer are conflicting, whereas no previous study has examined the association between use of fertility drugs and benign epithelial ovarian tumors.

Study design, size, duration: Retrospective register-based cohort study of nearly 145,000 women included in the Danish Infertility Cohort during 1995–2017 at age 20–45 years. Women were followed from one year after infertility diagnosis until first benign epithelial ovarian tumor or one of the censoring criteria: borderline ovarian tumor, ovarian cancer, oophorectomy, emigration, death or end of follow-up (December 31, 2018).

Participants/materials, setting, methods: Using the Aalen-Johansen estimator, we determined 10-year cumulative risks of benign epithelial ovarian tumors among approximately 25,000 women who used fertility drugs (defined within one year after infertility diagnosis: clomiphene citrate, gonadotropins, human chorionic gonadotropin, gonadotropin-releasing hormone [GnRH] receptor modulators, and progesterone) compared with women diagnosed with infertility and no drug use. Additionally, we used Cox proportional hazards regression models to calculate hazard ratios (HRs) and 95% confidence intervals (CIs).

Main results and the role of chance: Our results showed that the crude 10-year cumulative risk of benign epithelial ovarian tumors were 0.32% (95% CI: 0.29%–0.36%) for women who used any fertility drug compared with 0.49% (95% CI: 0.40%–0.60%) in women with no use of fertility drugs (risk difference: -0.17% [95% CI: -0.28–(-0.07)]). When adjusted for age, calendar period of infertility diagnosis, educational level, parity, obesity, polycystic ovary syndrome, and origin of infertility information, the HR for use of any fertility drug was 0.73 (95% CI 0.55–0.96). In general, the 10-year risk differences as well as the HRs for each drug evaluated separately were similar to the results for use of any drug. Lastly, we tested the robustness of our results by various pre-defined secondary analyses, and this did not change our results.

Limitations, reasons for caution: We did not include information on number of cycles and treatment regimens as these are only partly available in the registers.

Wider implications of the findings: Among women with infertility, we observe a lower relative risk of benign epithelial ovarian tumors for women treated with fertility drugs compared with women who did not use fertility drugs. However, this finding translates into a small decrease in absolute risk, which does not appear to have any clinical relevance.

Trial registration number: Not applicable

POSTER DISCUSSION SESSION

P-172 Effect of anti-centromere antibodies on multi pronuclear formation

Y. Kumagawa[1,2], K. Ihara[1,2], M. Tokoro[1,2], N. Fukunaga[1,2], Y. Asada[1,2]

[1]*Asada Ladies Clinic, Laboratory, Nagoya, Japan*
[2]*Asada Institute for Reproductive Medicine, Laboratory, Kasugai, Japan*

Study question: Do the anti-centromere antibodies (ACA) affect the multi pronuclear formation (MPF) rate?

Summary answer: MPF rate was higher in patients with ACA. The MPF rate of ACA patients with antibody titers ≥160-fold was significantly higher than in titers 40-fold.

What is known already: ACA is an anti-nuclear antibody (ANA), and specifically recognizes the centromere. Recently, several studies have reported that the rate of oocyte maturation is lower in patients with ACA. Moreover, in MI oocytes collected from ACA patients, female chromosomes were frequently dispersed in the cytoplasm.

Study design, size, duration: A total of 4756 patients from our clinic were tested for ANA before oocyte retrieval from January 2014 to December 2021. After retrospective ANA testing, patients were classified according to 3 groups; 62 ACA patients (with only ACA), 1134 non-ACA patients (with ANA but not with included ACA) and 3560 non-ANA patients (without ACA and any ANA).We considered ACA-positive levels at titers ≥40. ACA patients were further classified into 6 groups by antibody titer.

Participants/materials, setting, methods: The MPF rate after ICSI was compared in the 3 groups (ACA patients, non-ACA patients, non-ANA patients) and at 6 ACA titers in each group (titer of ACA; 40-fold, 80-fold, 160-fold, 320-fold, 640-fold, ≥1280-fold).MPF rate was calculated by dividing the number of embryos that formed three or more pronuclei by the number of embryos inseminated by ICSI.Ryan's method was used for multiple comparisons of ratios.

Main results and the role of chance: MPF rate was 3.8% (1997/53240) in non-ANA patients, 4.3% (733/17003) in non-ACA patients, and 32.1% (351/1092) in ACA patients, being significantly higher in ACA vs other groups (P<.01). In comparisons between ACA titers, MPN rate was 8.7% (4/46) at 40-fold , 13.0% (3/23) at 80-fold , 36.1% (56/155) at 160-fold , 32.4% (48/148) at 320-fold , 36.0% (111/308) at 640-fold , and 31.3% (129/412) at ≥ 1280-fold, respectively. MPN rate of patients with titers ≥160-fold was significantly higher than with 40-fold.

Limitations, reasons for caution: A potential limitation of the present study is the small sample size. This is because ACA patients account for only 1% of patients who underwent ART treatments.

Wider implications of the findings: MPF rate in ACA patients was significantly higher than in non-ANA and non-ACA patients and was also significantly higher in ACA patients with titers of ≥ 160-fold vs 40-fold. The dispersion of the female chromosome in the cytoplasm of MI oocytes may be a cause of MPN formation.

P-171 Identification of aneuploid embryos using cell free DNA in embryo culture medium

F. Kondo[1,2], H. Kitasaka[1,2], H. Watanabe[1,2], Y. Kida[1,2], S. Takeda[1,2], N. Fukunaga[1,2], Y. Asada[1,2]

[1]*Asada Ladies Clinic, Nagoya-Building 5F- 4-6-17 Meieki Nakamura-ku, Nagoya, Japan*
[2]*Asada Institute for Reproductive Medicine, RUNEK 3F- 1-4 Matsushin-cho, Kasugai, Japan*

Study question: Can noninvasive preimplantation genetic testing (PGT) using cell free DNA from embryo culture medium discriminate embryonic aneuploidy status?

Summary answer: Aneuploid embryos in older patients can be identified by cell free DNA in embryo culture medium.

What is known already: There have been reports of non-invasive PGT by analysing cell free DNA (cfDNA) released from embryos into culture medium, and found to be highly correlated with the analysis results of Trophectoderm (TE)-biopsy (Carmen.Rubio, 2020).We have initiated in 2021, a preliminary research program for the clinical application of niPGT. In aneuploid embryos, we have found a tendency for a high concordance rate between cfDNA analysis and blastocyst analysis results, suggesting the usefulness of cfDNA analysis in terms of identifying aneuploid embryos.Subsequently, we examined the usefulness of cfDNA analysis by comparing the concordance rate with cfDNA analysis and TE biopsy of blastocysts.

Study design, size, duration: After thawing pronuclear-stage frozen embryos for which consent was obtained for research use, they were co-cultured until Day 4, and then individually cultured on in new dishes.40 embryos that reached morula on day 4 or day 5 and blastocyst on day 6 or day 7 were included.

Participants/materials, setting, methods: The biopsied TE, the biopsied blastocyst, and the cfDNA obtained after individual culture were all sent to an external provider (Igenomix: Valencia, Spain) for chromosomal aneuploidy analysis by NGS. The concordance rate of the analysis for blastocysts in cfDNA and TE was calculated by dividing them into euploidy and aneuploidy, and by age. Concordance between the results of the blastocyst analysis and the culture medium were assessed according to the standards of the inspection company.

Main results and the role of chance: For the blastocyst analysis results, the concordance rate with cfDNA was 76.5% (26/34) and the concordance rate with TE was 85.3% (29/34), showing no difference. For the euploid blastocysts analyzed, the matching rate with cfDNA was 61.1% (11/18) and with TE was 77.8% (14/18), showing no difference. Similarly, for aneuploid blastocysts, the concordance rate with cfDNA was 93.8% (15/16) and with TE was 93.8% (15/16), showing no difference. Detailed analysis of aneuploid blastocysts revealed that the concordance rate with cfDNA was 88.9% (8/9) and the concordance rate with TE was 88.9% (8/9) in women under 39 years of age. In addition, the concordance rate with cfDNA was 100.0% (7/7) with TE was 100.0% (7/7) in those aged 40 and over. (Fisher's exact test)

Limitations, reasons for caution: Concordance between cfDNA and blastocyst analyzes in euploid embryos was low, continued follow-up is considered necessary.

Wider implications of the findings: In a detailed analysis of aneuploid blastocysts aged 40 years or older, Similar to TE, cfDNA showed a high concordance rate with the results of blastocyst analysis, demonstrating that cfDNA provides sufficient accuracy for identifying aneuploid embryos in women over 40 years of age.

P-152 Velocity of cytoplasmic movement in trophectodermal cells depends on the keratin cytoskeleton

A. Walewska[1], I. Pilaszek[1], A. Ajduk[1]

[1]*University of Warsaw- Faculty of Biology- Institute of Developmental Biology and Biomedical Sciences, Department of Embryology, Warsaw, Poland*

Study question: Can dysfunction of the keratin cytoskeleton, known to severely hinder postimplantation development of mammalian embryos, be detected by analysis of cytoplasmic movement in trophectodermal cells?

Summary answer: Depletion of keratins increases cytoplasmic movement in trophectodermal cells in extent depending on the developmental stage and on the location of the trophectodermal cells (mural/polar).

What is known already: Recent literature data indicate that keratins, intermediate filament proteins, are key regulators of trophectoderm function in mouse and human embryos. Keratin knockouts display trophoblast fragility, placental bleeding, and lethality after implantation. However, depletion of keratin 8 (Krt8) and keratin 18 (Krt18), which are most abundant in preimplantation embryos, does not lead to severe phenotype up to the blastocyst stage at least in mice and cattle, so can easily remain unnoticed. However, it affects the biomechanical properties of the trophectoderm. Analysis of cytoplasmic movement allows for biomechanical assessment of the trophectoderm in a non-invasive way.

Study design, size, duration: We analyzed 188 mouse embryos (66 control, 60 with Krt8 depletion, and 62 with Krt18 depletion) to quantitatively assess changes in the velocity of cytoplasmic movement caused by a knockdown of Krt8 and Krt18. Additionally, we correlated the velocity of cytoplasmic movement in trophectodermal cells ($n = 70$ embryos) with the ability to form outgrowths. Appropriate statistical tests were used to determine the statistical significance of the obtained results. A value of $p < 0.05$ was considered statistically significant.

Participants/materials, setting, methods: Zygotes were injected with Krt8 and Krt18 siRNAs or with scrambled siRNAs used as a negative control. The efficiency of the knockdown was tested on mRNA and protein levels. The embryos were cultured for 3 or 4 days and the velocity of cytoplasmic movement in polar and mural trophectoderm cells was measured. Additionally, we correlated the cytoplasmic movement velocity in trophectodermal cells in E3.5 embryos with their ability to implant in vitro (i.e., form outgrowths).

Main results and the role of chance: Our research showed that the velocity of cytoplasmic movement of trophectodermal cells varies depending on the embryo's developmental stage. Namely, the velocity of cytoplasmic movement was higher in E3.5 blastocysts than in E4.5 blastocysts. In addition, the velocity of cytoplasmic movement was higher in polar (8.45 ± 2.64 nm/s in E3.5 and 6.79 ± 1.96 nm/s in E4.5 control embryos) than in mural (6.30 ± 2.30 nm/s in E3.5 and 4.98 ± 1.89 nm/s in E4.5 control embryos) trophectodermal cells. Noteworthy, the depletion of Krt8 and Krt18 increased the velocity of cytoplasmic movement both in the mural and polar trophectodermal cells. However, it appears that changes caused by the depletion of these keratins depend on the embryo's developmental stage. For example, the depletion of Krt18 increased the velocity of cytoplasmic movement in mural trophectodermal cells in E3.5 embryos (9.61 ± 3.80 nm/s), while the depletion of Krt8 - in E4.5 embryos (6.65 ± 2.35 nm/s). In addition, data from our preliminary experiments with in vitro implantation suggested that embryos characterized by the higher cytoplasmic movement velocity were unable to form an outgrowth. The above data suggest that the velocity of cytoplasmic movement depends on the keratin cytoskeleton and probably can be used to predict an embryo's ability to implant.

Limitations, reasons for caution: We used mouse embryos, a well-established model of early mammalian embryo development. However, analogous experiments should be repeated on other mammalian species, including humans, if we wish to pursue the possibility that cytoplasmic velocity in trophectodermal cells is an embryo quality marker.

Wider implications of the findings: Our data indicate that cytoplasmic velocity in trophectodermal cells may be a valuable tool in embryo quality assessment, as it reflects the functionality of the keratin cytoskeleton in embryos as well as correlates with the embryos' ability to implant.

P-170 A sibling oocyte study using a real-time image analysis system to identify optimal puncture positions in Piezo-ICSI

T. Maekawa[1], T. Morimoto[1], S. Mizuta[1], H. Matsubayashi[1], T. Takeuchi[1], Y. Hata[2], T. Ishikawa[1]

[1]Reproduction Clinic Tokyo, Reproductive medicine, Tokyo, Japan
[2]University of Hyogo, Graduate School of Simulation Studies, Kobe, Japan

Study question: Is the newly developed image analysis system capable of visualizing the shape features of the oolemma in real-time, useful for reducing oocyte degeneration during Piezo-ICSI?

Summary answer: Unintentional membrane rupture (UMR) can be reduced by this real-time image analysis, which lowers the risk of oocyte degeneration following Piezo-ICSI.

What is known already: UMR in the puncturing process of ICSI often predisposes oocyte degeneration. Identifying the appropriate puncturing positions may decrease the likelihood of UMR and thus degeneration, but this cannot be visualized via a microscope. We have reported that visualization of the shape features of the oolemma using moving image analysis during Piezo-ICSI can locate areas on the oolemma where UMR is likely to occur. It is feasible to assess the incidence of UMR and oocyte degeneration by performing ICSI while selecting appropriate puncturing positions with the aid of the newly developed imaging system.

Study design, size, duration: Our team have developed an image analysis system called ICSI POSITION DETECTOR (IPD), which can identify areas where rupture is likely to occur and visualize it in real-time using a video monitor. We prospectively evaluated the usefulness of IPD in a sibling oocyte study. From January 2020 to August 2021, a total of 1268 oocytes obtained in 225 oocyte retrieval cycles (average maternal age: 38.3 ± 4.7 years old) was included.

Participants/materials, setting, methods: The oocytes were randomly assigned to two groups: IPD-using vs. non-IPD-using. In the IPD-using group, Piezo-ICSI was performed at the "appropriate" position with a low chance of UMR indicated by IPD. In the non-IPD-using group, Piezo-ICSI was performed blindly. The rates of UMR, oocyte degeneration, fertilization and embryonic development were compared between the two groups. In addition, in the non-IPD-using group, moving images were recorded during Piezo-ICSI and analyzed retrospectively using IPD.

Main results and the role of chance: The rates of UMR and degeneration were significantly lower in the IPD-using group compared to the non-IPD-using group (6.0% vs. 11.9%, $P < 0.001$ and 1.6% vs. 4.6%, $P < 0.01$, respectively). The rates of fertilization (83.7% vs. 79.7%), blastocyst formation (51.9% vs. 51.0%), and good-quality blastocyst (24.7% vs. 24.3%) were not significantly different. Retrospective analysis of moving images using IPD on the non-IPD-using group showed that in 45.3% of oocytes (286 out of 632) ICSI was performed at a position with a high chance of UMR (inappropriate position). When ICSI was performed at the appropriate positions using IPD, the rates of UMR (6.0% vs. 18.2%, $P < 0.001$) and degeneration (1.6% vs. 7.3%, $P < 0.001$) were significantly lower, while the rates of fertilization (83.7% vs. 74.5%, $P < 0.01$) and blastocyst formation (51.9% vs. 43.0%, $P < 0.05$) were significantly higher than those when ICSI was performed at an inappropriate position. The rate of good-quality blastocyst (24.7% vs. 19.7%) was also higher, but not statistically significant. These results indicate that IPD can reduce the risk of UMR, thereby lower the degeneration rate. Furthermore, the embryonic development was better when using IPD to identify the appropriate position to perform ICSI, suggesting that UMR seems to be associated with poor ICSI outcome.

Limitations, reasons for caution: In this study, Piezo-ICSI was performed by only two designated embryologists in a single center. It did not assess clinical outcomes. Further research involving more embryologists is needed. Moreover, it would be feasible to investigate whether the usage of IPD is similarly effective on conventional-ICSI outcome.

Wider implications of the findings: The application of IPD to perform ICSI at the appropriate position can significantly avoid UMR, and thereby reduce oocyte degeneration and provide better embryonic development. We therefore, consider IPD to be a highly clinically useful tool, which contributes to the production of more embryos that can be used for treatment.

P-201 Developmental analysis of blastocysts with blastomere exclusion during compaction and its relationship to pregnancy outcomes and preimplantation genetic testing for aneuploidy results

S. Nakano[1], M. Shioya[1,2], T. Sugirura[1], M. Fujita[1], K. Takahashi[1]

[1]Takahashi Women's Clinic, Reproductive Medicine, Chiba-Shi, Japan
[2]Chiba University Graduate School of Medicine, Reproductive Medicine, Chiba-Shi, Japan

Study question: What effects do blastocysts with blastomere exclusion during compaction have on embryo morphokinetics, morphology grade, genetic testing for aneuploidy (PGT-A) results, and pregnancy outcomes?

Summary answer: Blastocysts with blastomere exclusion leads to delay blastulation and poor morphology grade, but does not affect pregnancy outcomes and euploidy in PGT-A.

What is known already: It has been reported that aneuploid blastomeres are excluded during compaction, which is a mechanism for chromosome repair in blastocysts through the exclusion of aneuploid cells.Furthermore, in this phenomenon, it is known that the first cleavage of embryos is often abnormal, in which three or more cells originate from a single cell division event.However, this phenomenon has not been reported in the evaluation of embryo morphokinetics, artificial intelligence (AI) scores, or PGT-A results.

Study design, size, duration: In this retrospective study, we analyzed clinical medical reports at the Takahashi Women's Clinic in Japan. We included 934 blastocysts cultured in a time-lapse incubator (EmbryoScope) after intracytoplasmic sperm injection (ICSI) from January 2018 to June 2021.

Participants/materials, setting, methods: Blastocysts cultured using a time-lapse incubator (EmbryoScope) after ICSI were classified into a control group ($N = 515$) with blastomere compaction or a BE group ($N = 419$) with blastomere exclusion during compaction. The first type of cleavage, AI score (IDAScore), embryo morphokinetics, and single frozen-thawed blastocyst transfer outcome were evaluated.Logistic regression analysis was performed to compare the two groups, considering patient age, blastocyst grade (Gardner classification), culture days, body mass index, and basal anti-Müllerian hormone level.

Main results and the role of chance: Comparing the control and BE groups, the first cleavage abnormality rate was 16.9% vs. 67.3% ($P < 0.001$), the percentage with good embryo grade (Gardner criteria ≧BB) was 93.4% vs. 61.0% ($P < 0.001$), and the mean score by AI analysis was 8.3 ± 1.3 vs. 6.4 ± 1.9 ($P < 0.001$), respectively. The BE group had a higher rate of abnormal cleavage and a significantly worse embryo grade and AI score than the control group.In the evaluation of embryo morphokinetics, the time to morula was 84.2 ± 7.0 h vs. 89.0 ± 8.5 h ($P < 0.05$) and time to blastocyst was 105.9 ± 9.4 h vs. 114.7 ± 11.4 h ($P < 0.05$). The BE group significantly delayed blastulation compared to the control group.The euploidy, mosaicism, and aneuploidy rates of PGT-A were 13.6% (9/66), 9.1% (6/66), and 77.3% (51/66) in the control group vs. 13.2% (5/38), 13.2% (5/38), and 73.7% (28/38) in the BE group, respectively. There was no significant difference in the PGT-A results between the two groups. Furthermore, the single-blastocyst transfer pregnancy rates (gestational sac with heart activity) in the control and BE groups were 47.1% (147/312) and 32.6% (60/184), respectively. Pregnancy rate was lower in the BE group, but was not significantly different from that of the control group.

Limitations, reasons for caution: The study was conducted at a single in vitro fertilization center. Embryo transfer results were based on ongoing pregnancies, while live birth data for all pregnancies are not yet available.

Wider implications of the findings: Although the BE group was graded worse, statistical analysis considering the grade showed no significant difference in PGT-A and pregnancy rates between the two groups.These results suggest that blastocysts with blastomere exclusion can be useful as transferable embryos if they grow to a transferable grade.

P-217 Artificial intelligence (AI)-supported MAGENTA oocyte assessments shown to prospectively correlate with utilizable blastocyst development in patients, and for the first time in oocyte donors

J. Pons Ballester[1], M. Alavés[1], J. Teruel[1], J. Fjeldstad[2], N. Mercuri[2], A. Krivoi[2]

[1]*Equipo Médico Juana Crespo, IVF Laboratory, Valencia, Spain*
[2]*Future Fertility, Clinical Embryology and Scientific Operations-, Toronto, Canada*

Study question: Can MAGENTA, an AI oocyte assessment tool, prospectively assess the quality of oocytes retrieved from patients and donors as it relates to reproductive outcomes?

Summary answer: MAGENTA AI oocyte assessments provide insights on the quality of mature oocytes retrieved from both patients and young donors that correlate with utilizable blastocyst development.

What is known already: Oocyte donation has increasingly become a treatment path for many patients struggling with infertility. With specific criteria, oocyte donation aims to provide higher quality oocytes to increase the chances of success for recipients. However, not all oocytes from even a young donor will be of the same quality or have the same chances of reproductive success. MAGENTA is a non-invasive oocyte AI image analysis tool that provides an assessment of oocyte quality through a score on a scale of 0-10. MAGENTA scores in patient oocytes have previously been shown to correlate with subsequent development of a blastocyst, and its quality.

Study design, size, duration: A prospective study was conducted from April-November 2022 by Equipo Médico Crespo (Valencia, Spain) utilizing MAGENTA to assess the oocyte quality of patient and donor oocytes by assigning a score on a scale of 0-10. MAGENTA scores of denuded metaphase II (MII) oocytes were assessed for correlation to reproductive outcomes (fertilization and blastocyst development). 1,313 fresh MII oocytes retrieved from 126 subjects (68 patients, 59 donors) between the ages of 19-47 were included for analysis.

Participants/materials, setting, methods: Prior to ICSI, a non-invasive light microscopic image was taken of denuded MII oocytes utilizing specialized image capture software. Images were uploaded and analyzed by MAGENTA to provide a score, which remained blinded for the duration of the study. Reproductive outcomes regarding each mature oocyte were collected over the fertility cycle. Blastocyst development was defined by a Gardner grade by Day 5/6 post-ICSI. A utilizable blastocyst was considered a Gardner grade of 2CC or greater.

Main results and the role of chance: The following comparisons were assessed by Welch's Two Sample t-tests.

Overall, successfully fertilized oocytes had higher mean MAGENTA scores (4.5) than those that did not (3.9) ($p < 0.01$); furthermore, those oocytes that successfully developed into a blastocyst had higher mean MAGENTA scores (4.8) than those that did not (4.0) ($p < 0.01$).

Patient oocytes were found significantly older (mean age: 38.5) compared to donated oocytes (mean age: 25) ($p < 0.01$).

Patient oocytes that successfully developed into a blastocyst had a higher mean MAGENTA score (4.7) than those that did not (4.0) ($p < 0.01$); similarly, donated oocytes that successfully developed into a blastocyst had a higher mean MAGENTA score (4.9) than those that did not (4.1) ($p < 0.01$).

The MAGENTA scale was divided into 4 groups: A: 0-2.5 (346 oocytes); B: 2.6-5 (454 oocytes); C: 5.1-7.5 (358 oocytes); D: 7.6-10 (155 oocytes), over the whole dataset.

There was an overall increasing proportion of oocytes that developed into not only blastocysts, but more impressively, utilizable blastocysts from the lowest to highest MAGENTA score groups with significant differences between the patient oocytes scored in group B(38%) and C(50%) ($p < 0.05$), and the donated oocytes scored in group A(39%) and B(52%), and group C(54%) and D(66%) ($p < 0.05$) by Two Proportions Z-tests.

Limitations, reasons for caution: This study was conducted in fresh oocyte ICSI cycles. The use of frozen patient and donor oocytes should be assessed by VIOLET prior to vitrification, which takes into consideration freezing and thawing statistics. Further data is required to determine any correlation of MAGENTA with embryo ploidy or implantation status.

Wider implications of the findings: MAGENTA's a valuable tool for oocyte quality assessments correlating with utilizable blastocyst development amongst both autologous and donated oocytes. Although young donors are assumed to have high quality oocytes, this is not always true. MAGENTA assessments for donor oocytes could be essential to provide insights when these cycles unexpectedly fail.

[11]*ESHRE Central Office, Meerstraat 60, Grimbergen, Belgium*

Study question: What are the reported data on cycles in ART, IUI and fertility preservation interventions in 2020 as compared to previous years and what are the main trends over the years?

Summary answer: author: The 24rd ESHRE report on ART and IUI shows a progressive increase in reported treatment cycle numbers in Europe, a small decrease in the number of transfers (IVF + ICSI) with more than one embryo with a trend to decreasing multiple delivery rates, outcomes for IUI cycles are similar to previous years. WHAT IS KNOWN ALREADY: Since 1997, ART

aggregated data generated by national registries, clinics or professional societies have been collected, analyzed by the European IVF-monitoring Consortium (EIM) and reported in 23 manuscripts published in Human Reproduction and Human Reproduction Open.

Study design, size, duration: Yearly collection of European medically assisted reproduction (MAR) data by EIM for ESHRE. The data on treatments performed between January 1 and December 31 2020 in 35 European countries were provided by either National Registries or registries based on personal initiatives of medical associations and scientific organizations.

Participants/materials, setting, methods: In all, 1157 clinics offering ART services in 35 countries reported a total of 713 708 treatment cycles, involving 110 097 with IVF, 253 095 with ICSI, 239 759 with frozen embryo replacement (FET), 46 610 with preimplantation genetic testing (PGT), 59 906 with egg donation (ED), 344 with IVM of oocytes and 3897 cycles with frozen oocyte replacement (FOR). European data on IUI using husband/partner's semen (IUI-H) and donor semen (IUI-D) were reported from 1176 institutions offering IUI in 28 and 18 countries, respectively. A total of 102 702 treatments with IUI-H and 36 476 treatments with IUI-D were included. A total of 18 270 fertility preservation (FP) interventions from 15 countries including oocyte, ovarian tissue, semen and testicular tissue banking in pre-and post-pubertal patients were reported.

Main results and the role of chance: In total, 1157 IVF clinics participated (88.5% of registered clinics in the participating countries). Next to these also 1176 IUI units reported their data. In the 35 reporting countries, after IVF the clinical pregnancy rates (PR) per aspiration and per transfer in 2020 were similar to those observed in 2019 (27.9% and 32.9% versus 28.5% and 34.6%, respectively). After ICSI the corresponding rates were also similar to those achieved in 2019 (24.3% en 32.2% versus 26.2% and 33.5%). After FET with own embryos, the PR per thawing is stabilizing, 35.1% in 2019 and 34.6% in 2020. After ED the PR per fresh embryo transfer was 50.4% (50.5% in 2019) and per FOR 45.3% (44.8% in 2019). In IVF and ICSI together, the trend towards the transfer of fewer embryos continues with the transfer of 1, 2, 3 and $\geq$4 embryos in 62.1%, 32.3%, 2.2% and 0.3% of all treatments, respectively (corresponding to 55.4%, 39.9%, 2.6% and 0.2% in 2019). This resulted in a proportion of singleton, twin and triplet DRs of 90.5%, 9.3% and 0.2%, respectively (compared to 87.7%, 12.0% and 0.3%, respectively in 2019). Treatments with FER in 2020 resulted in twin and triplet DR of 7.0% and 0.1%, respectively (versus 9.3% and 0.1% in 2019). After IUI, the DRs remained similar at 8.9% after IUI-H (9.2% in 2019) and at 12.4% after IUI-D (12.1% in 2019). Twin and triplet DRs after IUI-H were 8.3% and 0.4%, respectively (in 2019: 8.7% and 0.3%) and 5.8% and 0.2% after IUI-D (in 2019: 6.2% and 0.2%). The majority of FP interventions included the cryopreservation of oocytes (n = 5 365 from 14 countries) and of ejaculated sperm (n = 11 571 from 14 countries).

Limitations, reasons for caution: As the methods of data collection and levels of completeness of reported data vary among European countries, the results should be interpreted with caution. For this abstract, some countries were not able to provide adequate data about the number of centers and initiated cycles and deliveries. WIDER IMPLICATIONS OF THE FINDINGS: The 24rd ESHRE report on ART and IUI shows a continuous increase of reported treatment numbers and MAR-derived live births in Europe. Being already the largest data collection on MAR in Europe, continuous efforts to stimulate data collection and reporting strive for future quality control and completeness of the data and offer higher transparency and vigilance in the field of reproductive medicine.

Abstract title: International Committee for Monitoring Assisted Reproductive Technologies (ICMART) Preliminary World Report on ART, 2019

Study question: In 2019 what was the global utilization, effectiveness and safety of ART?

Summary answer: Globally, ART utilization and data collection continue to increase but with wide variations in utilization, effectiveness and safety.

What is known already: ICMART began ART global data collection in 1991. Utilization, effectiveness and safety have continuously improved with more cycles, higher pregnancy rates and lower multiple birth rates, the latter due to the transfer of fewer embryos. Frozen embryo transfer (FET) and donor egg cycles continue to increase. However, wide variations in practice and outcomes exist globally. Approximately 10 million ART babies have been born. ICMART has helped develop registries internationally. A new electronic data collection platform has been developed with the University of New South Wales (UNSW) in Sydney, Australia; nevertheless, data collection and quality remain challenging.

Study design, size, duration: Countries and regions annually collect ART data, some prospectively and others retrospectively. ICMART retrospectively requested data from all known global sources for 2019 and reviewed them for missing or incorrect data. The dataset was reviewed and corrected by ICMART, in partnership with UNSW for validation and analysis, then ICMART finalized the results tables. Standardized definitions from The International Glossary on Infertility and Fertility Care, 2017, and previously developed methods were used. Preliminary results are presented.

Participants/materials, setting, methods: The European IVF Monitoring Consortium (EIM), Latin American Network of Assisted Reproduction (REDLARA), Australian/ New Zealand Registry and African Network and Registry for ART (ANARA) submitted regional data, and other countries contributed national data, through standardized formats, to ICMART. A few individual clinics with no registry access also contributed. Data received were reviewed, corrected, and validated to the extent possible, analyzed and summarized by ICMART using descriptive statistics.

Main results and the role of chance: Data collection and analysis are ongoing, so the presented results are preliminary. The number of ART cycles continues to increase, but utilization is still highly variable among countries and regions. Regional and country differences persist in the age of women treated, number of embryos transferred, live birth rates, rate of multiple births, use of ICSI, cryopreservation cycles and other factors.

The role of chance is minimal. Actual global ART results are limited to reporting countries and clinics representing 90 to 95% of global cycles. However, this is a very large sample size from which imputation of total global results is performed.

Limitations, reasons for caution: Most, but not all, countries report to ICMART. Some countries have limited data and many countries have limited data validation. ICMART can perform only minimal verification of submitted data. Widespread adherence to consensus definitions provided in the Glossary takes time and requires translation into multiple languages. Standardization of validation and reporting is an ongoing process because of missing data and continuing changes in clinical practice.

Wider implications of the findings: ICMART World Reports standardize data, track trends, enable comparisons, stimulate questions and improve ART

quality. Better understanding of ART increases societal acceptance and support for equitable access and ART research.

O-155 Building bridges to harmonize different data collection systems worldwide - need and challenges

M.S. Kupka[1]

[1]*Gynaekologicum Hamburg / Ludwig-Maximilians University of Munich, Unit for infertility treatment and endocrinology, Hamburg, Germany*

In order to transfer data from individual IVF centers and a national register into a regional register and then merge this data into a world register, certain basic definitions must be established.

The treatment strategies of each country are influenced by the legislative and insurance framework.

The expectations of patient couples also vary greatly from region to region.

All of this can only work if there are definitions of what data is to be collected and in what way.

Above all, there are difficulties in creating statistics when the raw data first has to be adjusted and merged.

This article is intended to point out some difficulties, but also to show solution concepts.

O-156 Embryo-like models: Using 3D gastruloids to understand human development

N. Moris[1]

[1]*Francis Crick Institute, Developmental Models lab, London, United Kingdom*

The mammalian embryo develops through coordinated cell fate decisions that enable emerging spatiotemporal and morphogenetic complexity. While much insight into this process has been gained through studying model organisms, including mouse embryos, equivalent experiments are technically and ethically challenging in the human embryonic context. Instead, we use gastruloids: 3-dimensional aggregates of pluripotent stem cells that undergo multilineage differentiation to all three germ layers, polarise their gene expression and exhibit axial organisation that recapitulates many of the features of gastrulation and early organogenesis. By closely examining the dynamics and coordination of cell fate decisions and spatial gene expression organisation, we hope to better understand the regulatory logic behind early developmental events, particularly those that are human-specific. Likewise, by carefully manipulating the environment in which these gastruloids are grown, we can bias the structures towards particular lineages and morphological structures of interest. Doing so allows us to explore many of the principles of early development, and provides an opportunity to probe the mechanisms of biomedically-relevant conditions, such as congenital abnormalities.

O-157 Modelling human early development

L. David[1]

[1]*Université de Nantes, Inserm- CR2TI, Nantes, France*

Understanding human peri-implantation development is necessary to improve in vitro fertilisation. Technical progress, such as scRNAseq and integrated stem cell models have dramatically improved our ability to understand human peri-implantation development. However, in-depth analysis and systematic validation in human embryos remains necessary to build a reliable reference. Here, we started by integrating pre- and post-implantation scRNAseq embryo datasets to generate a peri-implantation reference, highlighting progression of fates during early human development. Second, we identified the dynamics of genes modules, groups of genes with similar expression pattern. In particular, this highlighted the hierarchy of transcription factor potentially driving cell fate progression. Importantly, we performed prolonged embryo culture to validate by immunofluorescence progression of EPI and TE fates. Moreover, we compared the expression profile of the identified markers in stem cell models. Finally, we used the combination of gene modules to benchmark blastoid models. Altogether, our study paves the way for modelling human peri-implantation development with stem cell models.

O-158 Prediction of implantation of vitrified-warmed blastocysts using a deep learning algorithm on a single post-warming image of each embryo

L. Conversa Martínez[1], **M.Á. Valera Cerdá**[1], **L. Bori Arnal**[1], **L. Murria Aguilar**[1], **A. Cobo Cabal**[2], **M. Meseguer Escrivá**[2]

[2]*IVI-RMA Valencia, IVF Laboratory, Valencia, Spain*

Study question: Can a deep learning algorithm determine the implantation likelihood of vitrified blastocysts from single time-point post-warming time-lapse images obtained from EmbryoScope?

Summary answer: A significant positive correlation was found between the score given by the deep learning algorithm and the implantation rate of the frozen blastocysts analyzed.

What is known already: Despite the safety and success of the vitrification technique, many of the best morphologically classified embryos prior to vitrification do not maintain their characteristics when returned to room temperature. Since artificial intelligence (AI) has been shown to be useful in assessing the quality of fresh embryos at different stages, it could also be used to predict the outcome of frozen embryo transfers. This is the first attempt to distinguish vitrified blastocysts that will implant from those that will not by applying deep learning on a single image taken in the period between warming and transfer.

Study design, size, duration: This retrospective single-centre study included 689 blastocysts with known implantation data. All of them were vitrified and warmed using the Cryotop method (Kitazato, Biopharma, Japan). Warmed embryos were assessed by experienced embryologists according to the ASEBIR morphological scoring system and the degree of expansion. Immediately after warming, blastocysts were placed in EmbryoScope (Vitrolife, Denmark) time-lapse incubators for 2-5 hours to let them re-expand until embryo transfer.

Participants/materials, setting, methods: A pre-transfer embryo image was provided to the algorithm (Life Whisperer Viability), which returned scores from 0 to 10. Data were analyzed by chi-square test or one-way ANOVA. Multivariate logistic regression analysis was performed including embryo score, oocyte origin (donated vs. autologous), oocyte age, patient age, oocyte handling (fresh vs. vitrified eggs), and day of vitrification (5 vs. 6). The area under the receiver operating characteristic (ROC) curve (AUC) was used to calculate evaluation performance.

Main results and the role of chance: There was a significant difference between the scores given to vitrified implanted and non-implanted embryos. The mean value was 4.98 [95% CI 4.70-5.26]* for non-implanted embryos and 6.16 [95% CI 5.84-6.48]* for implanted embryos. When dividing the embryo score by quartiles, the implantation rate for each quartile was 27.7% for Q_1, 33.7% for Q_2 (Odds ratio (OR)=1.31 [0.82–2.09]), 44.8% for Q_3 (OR = 2.05 [1.30–3.22]*) and 48.3% for Q_4 (OR = 2.46 [1.56–3.87]*). The contribution of each increased unit of the algorithm score to the implantation (OR = 1.16 [95% CI: 1.09–1.23]*) was statistically significant. The deep learning algorithm score successfully predicted implantation with an AUC of 0.65 [95% CI: 0.60–0.69]*. Moreover, the algorithm performed better than the ASEBIR morphological classification, which achieved an AUC of 0,62 [95% CI: 0.58–0.66] in predicting implantation. *$P < 0.001$.

Limitations, reasons for caution: Our clinic was not involved in the development of the algorithm. Furthermore, it was designed to assess fresh embryos prior to vitrification but not thawed ones, so this study should be considered an external trial. A post-warming full video analysis by AI could possibly provide additional information.

Wider implications of the findings: The use of predictive models on vitrified cycles may help to select the best frozen embryo for transfer and predict which embryos will result in implantation failure early enough to thaw another one with a better chance of success. It also indicates that AI can generalize to thawed embryo assessment.

O-159 Impact of open and closed methods of vitrification on oocyte mitochondria function and RNAseq transcriptome profile: a preclinical screening study

T. Adeniyi[1], A. Stevens[2], R. Sturmey[3], D. Brison[4]

[1]Manchester University NHS Foundation Trust MFT, Department of Reproductive Medicine- Old St Mary's Hospital Manchester- Maternal and Fetal Health Research Centre, Manchester, United Kingdom
[2]Manchester University, Division of Developmental Biology and Medicine, Manchester, United Kingdom
[3]University of Manchester, Maternal and Fetal Health Research Centre, Manchester, United Kingdom
[4]University of Manchestester, Maternal and Fetal Health Research Centre, Manchester, United Kingdom

Study question: Do current methods of open vitrification (OV) and closed vitrification (CV) impact on oocyte mitochondria function and transcriptome?

Summary answer: Oocyte vitrification confers unique mitochondria distribution patterns and alters the expression of stress response genes and mitochondria function relative to control (fresh) oocytes.

What is known already: Mitochondria are essential for maintenance of metabolic function and developmental competence at physiological conditions. Conversely, open and closed methods of oocyte vitrification are associated with physical, chemical and non-physiological changes, and exposures to cryoprotecting agents which could be harmful at extremely high and low temperatures.

Study design, size, duration: Ninety-four unfertilised Metaphase II (MII) oocytes were donated to research between May 2018 and August 2021. Fifty-seven oocytes were randomly allocated to the different study groups. Similarly, thirty-seven oocytes were allocated to the different study control groups.

Participants/materials, setting, methods: Fourteen women underdoing IVF/ICSI treatment cycles were involved in the study. cDNA was obtained for qPCR and the Smart-Seq2 protocol and single-cell RNA-Seq was performed (illumina NextSeq2000). Mitochondrial staining on live-oocytes was performed using Mito-tracker Deep Red stain, and images evaluated using fluorescence microscopy. Differentially expressed genes were identified using the R package edgeR and functional gene ontology was performed using an over-representation analysis via WebGestalt. Correction for multiple testing was calculated using Benjamini-Hochberg method

Main results and the role of chance: Mean mitochondrial intensity/density showed similarities between open (OV) and closed vitrification (CV) and control (fresh oocytes FO): 25.8 (12.7-44.9, standard deviation [SD] 10.2) for FO oocytes (n = 15), 30.3 (16.2-44.8, SD 10.1) for OV oocytes (n = 11), 26.6 (13.3-64.6, SD 15.3) for CV oocytes (n = 12) (p = 0.617). Distinct mitochondria distribution patterns (cytoplasmic and peripheral) were associated with OV and CV oocytes. Twice as many peripheral to cytoplasmic patterns were observed in FO and OV oocytes in contrast to CV oocytes (p = 037). Mean expression of the gene SDHB, which is associated with the TCA cycle and the mitochondrial electron transport chain was reduced in vitrified oocytes (n = 13) (0.0879 ± 0.0216 vs 0.0593 ± 0.0479), as was the anti-apoptotic gene BCL2 (p = 0.0061), relative to control oocytes (n = 13), (p = 0.01). Conversely, genes associated with apoptosis and stress response (BAX (p = 0.002) and BCL2L1 (p = 0.016)) were significantly enriched relative to control oocytes. RNAseq transcriptome analysis revealed a total of 71 differentially expressed genes following vitrification relative to control oocytes. Genes associated with critical metabolic processes (death domain binding, BCL-2 homology 3 (BH3) domains, and exopolyphosphatatse activities) were enriched in vitrified oocytes relative to the control group (FDR>0.05).

Limitations, reasons for caution: The use of unfertilised metaphase II (MII) oocytes on day 1 as a preclinical application screening model for vitrification may not reflect the molecular status and integrity of clinical grade MII oocytes on day 0.

Wider implications of the findings: This study emphasizes the inherent impact of vitrification on oocyte mitochondria function and transcriptome relative to control oocytes. Importantly, unintended perturbations may be detrimental to oocyte health and developmental competence, suggesting the need for a continuous safety screening and monitoring of ART methods of cryopreservation and offspring long-term health.

O-160 Do day of vitrification, grade of expansion and blastocyst quality affect embryo survival rate? An observational study in oocyte recipient patients

M. Lopez Rodriguez[1], Y. Garijo López[1], A. Arnanz Poyatos[1], F. Bronet Campos[1]

[1]IVI RMA Madrid, IVF Laboratory, Madrid, Spain

Study question: Which parameters are the most predictive of embryo survival rate in oocyte recipient cryotransfer cycles?

Summary answer: We have identified that only day of vitrification and grade of expansion have an impact on embryo survival rate

What is known already: Embryo vitrification is a well stablished technique that has led to survival rates around ± 96%. Recent studies, based on day of vitrification, grade of expansion and blastocyst quality, are trying to identify which vitrified blastocyst has the highest potential to survive and to implant. However, controversial results are present in the literature, improvements in laboratory quality parameters and embryo culture could unleash into no significant differences regardless of morphological parameters. Nevertheless, having an acceptable survival rate does not mean to have a good implantation rate, biomarkers to identify the best potential blastocyst to survive and to implant are needed

Study design, size, duration: An unicenter-based retrospective observational clinical study was performed at IVI Madrid, approved by the local institutional review board (IRB). The study included all the warmings at blastocyst stage from oocyte recipient patients from January 2019 to April 2022. A total of 4.196 of warmed blastocysts were assessed, out of which 4.006 blastocysts were transferred

Participants/materials, setting, methods: All warmed blastocysts were allocated in groups according to the day of vitrification, grade of expansion and quality. The primary outcome analysed was embryo survival rate that was calculated as the number of viable embryos divided by the total number of embryos warmed. Vitrification and warming were performed following

Kitazato method (Cryotop, Kitazato, Biopharma). Embryo classification was assessed previous vitrification according to IVIRMA criteria. Statistical analyses were conducted using univariate and multivariate regression model

Main results and the role of chance: The mean maternal oocyte recipient age was 42.27 ± 3.89 years old and body mass index 23 ± 3.74 kg/m2). In a multivariate logistic regression analysis, a statistically significant association between embryo survival rate and the day of vitrification and grade of expansion was found. Chance of survival was significantly reduced for blastocyst vitrified on day 6 (n = 737) compared to day 5 (n = 3459) (93,2 % versus 96,0% [OR = 0.976 (0.960-0.993); p=0.05]). Regarding grade of expansion, cavitated blastocyst (n = 840) survival rate was 97,7% [OR = 1;p<0.001], expanded blastocyst (n = 1866) was 96,2% [OR = 0.095 (0.978-1.013)], hatching blastocysts (n = 1465) was 94% [OR = 0.978 (0.960-0.997); p=0.02) and fully hatched blastocysts (n = 25) was 60% [OR = 0.704 (0.648-0.765);p<0.001)]. However, no association was found neither between lower inner cell mass quality [OR = 0.964 (0.842-1.104); p=0.596) nor trophoectoderm [OR = 1.004 (0.981-1.028); p=0.746)] and survival rate. Analysing the combination of these three variables will give us the possibility to choose the best embryo to warm. The impact of day of vitrification, grade of expansion and blastocyst quality on implantation, clinical pregnancy, miscarriage, and live birth rates will be included in further studies

Limitations, reasons for caution: A weakness of this study is that it is retrospective in nature. The single-group design employed in retrospective studies limits the researchers' ability to determine cause and effect. Further studies are needed to determine the impact of these variables on the survival rate

Wider implications of the findings: Based on our findings, blastocyst survival rate is influenced mostly by the day of vitrification and degree of expansion. To be able to select the best blastocyst to warm, a comparison between different day of vitrification when we have a similar morphology and embryo quality cohort is needed

Trial registration number: Not applicable

O-161 Performance of IDAScore prediction models on clinical, obstetric and neonatal outcomes of single vitrified-thawed blastocyst transfer

B. Huang[1], M. Bingxin[1], J. Lei[1]

[1]Huazhong University of Science and Technology, Tongji Hospital- Tongji Medicine College, Wuhan- Hubei, China

Study question: Does a free-annotation embryo scoring system (IDAScore) prediction model effective in clinical assisted embryo selection?

Summary answer: iDAScore could be used to predict the clinical pregnancy and live birth.

What is known already: iDAScore model, as a free-annotation and deep learning-based embryo scoring system, was created according to deep learning model by training 115,832 embryos and 14,644 known implantation embryos from 18 reproductive medical center. Then, every blastocyst was scored without any manipulation and intervention by embryologists. Although iDAScore's performance was validated by a few reproductive centers, it has not yet been verified in a sizable cohort study. As a result, the effectiveness of iDAScore should be assessed in more reproductive clinics.

Study design, size, duration: A total of 6,291 vitrified-thawed single blastocyst transfer (SBT) cycles from 2018 to 2021 at the Reproductive Medicine Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, were analyzed a free-annotation and deep learning-based embryo scoring system (IDAScore) (EmbryoScope Plus, Vitrolife, Sweden).

Participants/materials, setting, methods: All blastocysts undergoing SBT were scored from 1 to 9.9 with ida system. Blastocyst scores were grouped according to quartile.The effectiveness of ida system was evaluated according to clinical outcomes, perinatal and neonatal outcomes of different groups (1.0-8.0, 8.1-8.9, 9.0-9.3, 9.4-9.9).

Main results and the role of chance: The iDA scores decreased with increasing maternal age.

Clinical pregnancy rate and live birth rate increased with iDAScores, and there was a significant correlation ($p < 0.001$). The abortion rate decreased slightly with the increase of iDAScores, but there was no significant difference ($p > 0.05$). Ectopic pregnancy rate did not change significantly with iDAScores. No statistically significant difference were observed between single and twin live birth among different iDAScore groups ($p > 0.05$).

For perinatal and neonatal outcomes, no significant difference was shown in four iDAScore group ($p > 0.05$). Among them, gestational age and premature birth rate were similar ($p > 0.05$). Besides, no significant difference was shown in types and rate of pregnancy complication ($p > 0.05$). For newborn babies, the birth weight and sex were statistically similar across all groups ($p > 0.05$). The birth defect outcome was also evaluated. No significant difference were shown on different types of birth defect in all groups ($p > 0.05$).

The uni-variate and multi-variate logistic regression for live birth was also analyzed. iDAScore were significantly correlated with a positive live birth probability (OR: 1.200, 95% CI: 1.148-1.253, $p < 0.05$).

Limitations, reasons for caution: The experimental samples in this study are all blastocyst transfer cycles. There is no guiding significance for other centers using the cleavage embryo transfer cycle.

Wider implications of the findings: iDAScore could be used to predict the clinical pregnancy and live birth. For the blastocyst that has obtained live birth, different iDAScore did not cause significant differences in obstetric and neonatal outcomes. Therefore, iDAScore determined blastocyst implantation more than fetal development.

O-162 Fresh or frozen Day 6 blastocyst transfer : Is there still a question?

L. Ferreux[1], M. Bourdon[2], A. Chargui[1], C. Maignien[2], C. Chapron[2], P. Santulli[2], C. Patrat[1], K. Pocate-Cheriet[1]

[1]Assistance Publique – Hôpitaux de Paris AP- HP- APHP. Centre – Université de Paris- Hôpital Cochin-, Service de Biologie de la Reproduction et CECOS- Paris- France., Paris, France

[2]Assistance Publique – Hôpitaux de Paris AP- HP- APHP. Centre – Université de Paris- Hôpital Cochin-, Service de Gynécologie-Obstétrique II et de Médecine de la Reproduction- Paris- France, Paris, France

Study question: Whether slow developing expanded day 6 (D6) blastocysts should be either transferred during fresh cycle or systematically vitrified at D6

Summary answer: Fresh D6 blastocyst transfer is independently associated with reduced live birth rate compared to frozen thawed D6 transfer

What is known already: Live birth rate (LBR) after D5 blastocyst transfers are significantly higher when compared with D6 embryos in both fresh and frozen-vitrified embryo transfer cycles according to the last published meta-analyses. Therefore, for women obtaining only D6 blastocysts, chances of pregnancy may be lower but still persist and these embryos should be transferred. The question of the best strategy for transfer (i.e. in fresh or frozen cycles) remains unclear while data on this subject are scarce.

Study design, size, duration: Retrospective observational cohort study. Patients having only embryos reaching blastocyst stage at D6 were included between January 2018 and May 2021. Two groups were compared : patients having a fresh D6 transfer (D6 fresh transfer group) and patients having a frozen thawed D6 transfer (D6 frozen transfer group).

Participants/materials, setting, methods: 830 D6 single blastocyst transfers (736 frozen blastocysts and 94 fresh blastocysts) were analyzed. LBR and neonatal outcome were compared between groups, as well as the influence of clinical characteristics and data related to COS protocols. Correlation between D6 blastocyst morphology according to Gardner's classification and livebirth occurrence was also evaluated. Statistical analysis of the data was carried out using univariate and multivariate logistic regression models.

Main results and the role of chance: LBR was significantly lower after D6 fresh blastocyst transfer compared to D6 frozen thawed blastocyst transfer

[5.3% (5/96) vs 12.2% (90/736), $p < 0.05$]. Moreover, when comparing a subgroup of 68 first D6 frozen embryo transfers (1st D6 frozen transfer group) to the 94 fresh D6 blastocyst transfers (D6 fresh elective group), the superiority of D6 frozen blastocyst transfers regarding LBR was also confirmed (17.6% vs 5.3% $p < 0.001$, respectively). Concerning neonatal outcomes, the mean birth weight was comparable between the two groups. Univariate logistic regression analysis taking into account blastocyst morphology parameters showed that TE grade was the only parameter significantly associated with LBR after D6 embryo transfer ($p < 0.001$).

Multiple logistic regression revealed that D6 embryo fresh transfer was independently associated with reduced LBR compared to frozen thawed D6 transfer (OR 0.367; 95%IC 0.143-0.945; $p = 0.038$). Moreover, our results showed that transferring a good or top quality D6 blastocyst increases 3 fold chances of live birth.

Limitations, reasons for caution: The number of fresh cycles seems relatively small, but the consistency of our results was guaranteed by the homogeneity of the 2 subgroups, standardization of all biological and clinical procedures and the robust statistical analysis methodology used in this study.

Wider implications of the findings: Despite their lower potential, D6 blastocysts have to be transferred with the objective to improve LBR, especially in women obtaining only these type of embryos. Our results recommend to transfer D6 blastocysts in frozen cycles. However, these findings have to be confirmed on larger series in prospective randomized trials.

Abstract citation ID: dead093.196
O-163 The influence of aquaporin 3 on dynamics of cavitation, implantation and re-expansion after vitrification/warming

E. Kosyl[1], **A. Ajduk**[1]

[1]*University of Warsaw- Institute of Developmental Biology and Biomedical Sciences, Department of Embryology, Warsaw, Poland*

Study question: We wished to investigate whether aquaporin 3 (AQP3) is involved in trophectoderm-related events: cavity formation and maintenance, implantation and re-expansion after the vitrification/warming process.

Summary answer: AQP3 regulates blastocoel formation and expansion. It is also required for implantation (as assessed by in vitro implantation assay) and maintaining developmental potential after vitrification.

What is known already: During blastocoel expansion blastocyst pulsates, i.e. contracts and re-expands in an oscillatory way. Recent studies utilizing a mouse model have shown, that the dynamics of cavitation and biomechanical properties of the trophectoderm are intertwined, and our results suggest, that it may, to a certain extent, reflect the developmental capabilities of blastocysts. Moreover, the dynamics of blastocyst re-expansion after vitrification/warming is also suggested to be a promising biomarker of embryo quality. As AQP3 is involved in water influx and transportation of small molecules (such as cryoprotectants) through the epithelial layer, it is a good candidate for a regulator of blastocoel expansion.

Study design, size, duration: We analyzed 142 mouse blastocysts to correlate the dynamics of their cavitation with their ability to implant in vitro (an outgrowth assay). We investigated the expression of *Aqp3* throughout the preimplantation development. We tested how inhibition of AQP3 affects the dynamics of cavitation ($n = 37$; control $n = 118$) and formation of outgrowths ($n = 77$; control $n = 81$). We vitrified blastocysts with a limited activity of AQP3 ($n = 41$; control $n = 38$) and investigated their ability to re-expand and implant in vitro.

Participants/materials, setting, methods: The dynamics of cavitation was assessed by time-lapse imaging. After filming, mouse blastocysts were cultured for additional 4 days to test their ability to form outgrowths. Inhibition of AQP3 was performed by adding 100μM DFP00173 (a selective AQP3 inhibitor) to the culture medium. AQP3-inhibited blastocysts were analyzed for the dynamics of cavitation and outgrowth formation. Additionally, embryos with a limited activity of AQP3 were vitrified, warmed and then the outgrowth assay was performed.

Main results and the role of chance: Blastocysts unable to implant in vitro properly (i.e. forming too small outgrowths or not forming outgrowths at all) contract longer and more frequently than embryos that form correct outgrowths. Moreover, in such blastocysts, we observed shorter and weaker re-expansion phases. As AQP3 may be one of the regulators of cavitation, we followed its expression in embryos and showed that *Aqp3* mRNA level increases from the 2-cell to the morula stage. AQP3 protein can be found in the cytoplasm during cleavage and translocates to basolateral membranes in trophectodermal cells in blastocysts. We revealed that inhibition of AQP3 resulted in delayed cavity formation. Moreover, inhibition of AQP3 significantly weakened the blastocyst's ability to (re-)expand and also extended the duration and decreased frequency of the blastocoel contractions. Importantly, changes in the duration of contractions and amplitude of re-expansions were similar to those observed in blastocysts not able to implant in vitro properly. This accords with our observation that blastocysts with a limited activity of AQP3 are mostly unable to create outgrowths. Finally, we proved that inhibition of AQP3 strongly weakened re-expansion of the cavity after vitrification/warming. Furthermore, such blastocysts had a significantly lower ability to implant in vitro after vitrification.

Limitations, reasons for caution: We examined the role of AQP3 in blastocoel (re)-expansion and the relationship between cavitation dynamics and embryo's ability to implant only in mice, so additional studies on other mammalian species, including humans, are needed. Moreover, our in vitro implantation assay does not fully reflect the complexity of implantation in vivo.

Wider implications of the findings: Our data indicate, that AQP3 regulates the dynamics of blastocoel expansion in mouse embryos. Impaired dynamics of cavitation, unsuccessful implantation or vitrification failures might be a result of decreased AQP3 activity, possibly not only in a mouse but also in other mammalian species, including humans.

O-164 The emotional and ethical complexity of end of treatment in ART

D. Leone[1]

[1]*University of Milan- San Paolo Hospital, Department of Health Sciences, Milan, Italy*

In the context of Assisted Reproductive Technology (ART), the decision to end the treatment is very complex and involves emotional and ethical dimensions. It should occur after a series of failed attempts and when "the chances for a successful outcome are so low that it is in the patient's best interest to stop any further attempt at it"[1]. The lack of a clearly defined biological endpoint makes the decision to end treatment extremely challenging and is one of the most complex bad news within the doctor-patient relationship. The decision to end treatment can be experienced by patients as an existential failure; they are overwhelmed by all sorts of emotions related to the acknowledgment that the pregnancy they hoped for might eventually never happen. When treatment is interrupted, hope could be lost with feelings of intense sorrow, and failing to become a parent requires rethinking a new identity. Patients who end ART treatment may experience a crisis characterized by shock, denial, anger, frustration, and loss of control. Many patients approach ART treatment thinking that repeated attempts will sooner or later lead to the long-awaited pregnancy. This attitude could turn into "over-persistence", the condition in which patients insist on continuing ART treatment with very low or any chance of success. According to the literature, doctors may

mitigate patients' emotional distress related to the end of treatment (EoT) through effective communication, which has the potential to facilitate the process of acceptance and reduce psychological suffering.

Likewise, physicians may experience intense emotions (e.g., frustration, denial). Clinicians reported feelings ranging from the idealization of the process to impotence, and these emotions intertwined with a sense of duty could influence decisions about ART treatment and lead to compulsive use of ART procedures. Clinicians remain fully aware of the probability of success and perceive patients' expectations as a burden, resulting in performance anxiety.

The decision to end unsuccessful ART treatment also involves ethical aspects. In particular, the decision to end treatment raises the dilemma between beneficence and patient autonomy. The request for (over)persisting ART treatment may come from patients with a strong desire for parenthood, who do not accept the possibility of giving up on biological pregnancy. On one hand, any choice about EoT must be in accordance with the patient's self-determination; on the other hand, doctors should consider the patient's beneficence and favorable risk/benefit ratio. EoT should be considered as a matter of proportionality of care, recognizing that benefits may be less than the medical, economic, but especially psychophysical burdens. The value of distributive justice and equity must also be addressed. Owing to rising healthcare costs, health professionals have an ethical duty to manage medical services, eliminating all those non-essential procedures requiring a waste of resources and/or time with few or no significant results.

P-391 Importance of oxygen tension in human ovarian tissue in vitro culture

F. Vitale[1], **L. Cacciottola**[1], **F. Yu**[1], **M. Barretta**[1], **C. Hossay**[1], **J. Donnez**[2], **M.M. Dolmans**[3]

[1]*Université Catholique de Louvain - Institut de Recherche Expérimentale et Clinique, Gynecology Research Unit, Bruxelles, Belgium*
[2]*Société de Recherche pour l'Infertilité SRI, Society for Research into Infertility, Bruxelles, Belgium*
[3]*Université Catholique de Louvain - Cliniques Universitaires Saint-Luc, Gynecology Research Unit - Gynecology Department, Bruxelles, Belgium*

Study question: Is there any difference between 20% and 5% oxygen (O_2) tension on the viability and quality of human follicles contained in cultured ovarian cortex?

Summary answer: 5% O_2 yields higher follicle viability and quality than does 20% O_2 tension after 6 days of in vitro culture (IVC).

What is known already: The primordial follicle (PMF) pool resides within the ovarian cortex, where in vivo O_2 tension ranges between 2% and 8%. However, IVC is commonly performed at atmospheric O_2 tension (20% O_2), yielding low follicle survival rates. Elevated O_2 tension or insufficient antioxidant protection can cause excessive reactive oxygen species (ROS) accumulation, leading to DNA lesions, such as oxidative stress damage and double-strand breaks (DSB).

Study design, size, duration: This prospective experimental study included frozen-thawed ovarian cortex from 6 adult patients (mean age: 28.5 years; age range: 26–31 years) undergoing laparoscopic surgery for non-ovarian diseases. Ovarian cortical fragments were cultured for 6 days at (i) 20% O_2 with 5% CO_2, and (ii) 5% O_2 with 5% CO_2. Non-cultured fragments served as controls.

Participants/materials, setting, methods: Cortical fragments were analyzed according to: hematoxylin and eosin (H&E) staining for follicle count and classification; cleaved caspase-3 immunostaining to identify follicle apoptosis; 8-hydroxy-2-deoxyguanosine (8-OHdG) and gamma-H2AX (γH2AX) immunolabeling to detect oxidative stress damage and DNA DSBs; and β-galactosidase staining to assess follicle senescence. Droplet digital PCR was also performed to further explore gene expression of superoxide dismutase 2 (SOD2) from the antioxidant defense system, and cyclin-dependent kinase inhibitors (p21 and p16) as senescence-related genes.

Main results and the role of chance: Apoptosis ($p = 0.002$) and follicle senescence ($p = 0.03$) rates were significantly lower in the 5% O_2 than the 20% O_2 group. Moreover, granulosa cells (GCs) in follicles in the 20% O_2 group exhibited significantly ($p < 0.001$) higher oxidative stress damage rates than in the 5% O_2 group. DNA DSB damage rates in GCs of follicles were also significantly higher ($p = 0.001$) in the 20% O_2 than the 5% O_2 group. SOD2 values were significantly greater in the 5% O_2 group compared to the 20% O_2 group ($p = 0.04$) and the non-cultured group ($p = 0.002$). Expression of p21 was significantly increased in 20% O_2 ($p = 0.03$) and 5% O_2 ($p = 0.008$) compared to no culture. Moreover, the 20% O_2 group showed significantly greater p16 expression ($p = 0.04$) than the non-cultured group, while no significant variation was observed between 5% O_2 and no culture.

Limitations, reasons for caution: This study focuses on improving follicle outcomes during the first step of ovarian tissue IVC, where follicles remain in situ within the tissue. The impact of O_2 tension in further steps, such as secondary follicle isolation and maturation, was not investigated here.

Wider implications of the findings: Our findings suggest that 5% O_2 tension culture is a promising step towards potentially solving the problem of poor follicle viability after IVC.

P-394 Neurotrophin-4 supplementation during human secondary follicle in-vitro-culture supports morphologically normal blastocyst formation

Y.C. Guo[1], **L. Jia**[1], **P. Sun**[1], **W. Su**[1], **T. Li**[1], **C. Fang**[1]

[1]*The Sixth Affiliated Hospital- Sun Yat-sen University, Reproductive Medicine Research Center, Guangzhou, China*

Study question: Can matrix-free culture system supplemented with Neurotrophic factor 4 (NT4) improve human follicular development and achieve mature and fertile oocytes *in vitro*?

Summary answer: NT4 promotes the growth, steroid hormone production of human secondary follicles cultured *in vitro* (including post- and pre-pubertal patients), thereby yielding mature and fertile oocytes.

What is known already: Reconstituting folliculogenesis *in vitro* play vital roles in reproductive biology research, fertility preservation and reproductive toxicity testing. However, fertile oocyte from *in-vitro*-grown (IVG) human follicle remains unachieved. It has been demonstrated that NT4 promotes *in-vitro* survival, growth, and maturation of mice secondary follicles. NT4 and its receptors have been detected in human ovaries. However, if the advance proved in mice model is effective to replicate in human has not been reported.

Study design, size, duration: Discarded ovarian tissues after ovarian tissue cryopreservation (OTC) were collected from 6 patients aged from 11 to 21 years old who underwent unilateral oophorectomy for fertility preservation, after obtaining written informed consent. Isolated secondary follicles were

cultured *in vitro* with or without NT4 in a matrix-free system for 4-6 weeks individually.

Participants/materials, setting, methods: Secondary follicles isolated from each patient were randomly assigned to control or NT4 group, followed by incubation on the ultra-low attachment microplate individually. Follicle growth and survival were assessed by microscopy. Anti-Müllerian hormone (AMH), estradiol and progesterone levels were quantified in the medium. Oocyte marker expression was evaluated by DEAD box polypeptide 4 (Ddx4) staining. Oocyte mature and fertile potential were assessed by *in-vitro* maturation and intracytoplasmic sperm injection (ICSI) with donated sperm, separately.

Main results and the role of chance: In control condition, isolated follicles survived for 4-6 weeks with increased diameters over time ($P < 0.05$), reaching a terminal diameter of 967.00 ± 41.1 µm with the confirmed induction of steroidogenesis and expression of widely accepted oocyte markers (DDX4). Three out of twelve (25%) alive follicles were matured successfully *in vitro*, most of which produced morphologically normal MII oocytes with sizes of 120 ± 2.1 µm. The diameter and steroid hormone production were significantly higher in the group cultured with NT4 than in the control group ($P < 0.05$). An increased efficiency of MII oocyte production in the NT4 group was also observed, while the difference was not statistically significant. MII oocyte obtained from the control group showed abnormal fertilization after ICSI. In contrast, MII oocyte acquired from the NT4 group progressed to available blastocyst.

Limitations, reasons for caution: The population included were all patients with thalassemia. Whether this culture system is effective for patients with other diseases is unknown. Limited by the small sample, the effect of NT4 on maturation competence needs further confirmation. Oocytes obtained have not been quantified with ploidy status and epigenetic signatures.

Wider implications of the findings: Surplus ovarian tissue after OTC, which is otherwise discarded, may serve as an additional precious source of fertile oocytes for fertility preservation, even for pre-pubertal girls, without a threat of tumor reintroduction. The system described here will provide a powerful research tool for reproductive biology research and reproductive toxicity testing.

P-412 Long-term in vitro dynamic culture of bovine ovarian cortical tissue (BOCT) increases follicle growth, viability and AMH secretion

V. Barbato[1], V. Genovese[1], V. De Gregorio[1], A. Travaglione[1], A. Candela[1], G. Catapano[2], A. Amoresano[3], S. Serpico[3], G. Pinto[3], G. Mondrone[4], T. D'Hooghe[5], S. Longobardi[5], W. Zheng[5], R. Gualtieri[1], R. Talevi[1]

[3]University of Naples Federico II, Chemical Science, Naples, Italy
[4]IVF RED srl, IVF RED srl, Caserta, Italy
[5]Merck KGaA, Global Medical Affairs Fertility, Darmstadt, Germany

Study question: Does improved oxygen availability and biomechanical stimulation during long-term dynamic in vitro culture of BOCT enhance secondary follicles growth and health?

Summary answer: Long-term dynamic versus static in vitro culture of BOCT increases the proportion, viability and AMH secretion of growing follicles.

What is known already: A limiting factor in multistep in vitro folliculogenesis is the low yeld of healthy secondary follicles after ovarian cortical tissue culture. We previously reported that dynamic in vitro culture of ovarian cortical tissue for 7 days in a newly designed perifusion bioreactor (patent 102020000027290) enhances follicle growth and health compared to conventional static culture. The bovine represents a valuable animal model to study early folliculogenesis in vitro.

Study design, size, duration: Bovine ovaries (age 8-24 months) were collected from slaughterhouse. BOCT strips from the same ovary were cultured for 14 days in perifusion bioreactors (PB, dynamic culture) and conventional dishes (CD, static culture). BOCT cultured in both PB and CD was monitored by collecting spent media every 2 days and through histology, live-dead confocal analysis at the end of culture.

Participants/materials, setting, methods: BOCT slices (0.5mm thick) were obtained by a custom tissue slicer, chopped into 1x1mm strips and cultured in group of 10 under in PB and CD. Follicle stages and quality in fresh (D0) and cultured tissues were evaluated by histology (hematoxylin-eosin staining), follicle viability was estimated by labelling with live-dead far-red and propidium iodide at the confocal microscope. Whole tissue viability (spectrophotometric LDH assays) and AMH secretion (mass spectrometry) were evaluated on spent media.

Main results and the role of chance: Overall, 939 follicles were analyzed (histology, 338; viability, 601). Day 0-Follicle stages: primordial, 82.4%; primary, 13.2%; secondary, 4.4%; follicle quality: grade 1-2, 37,6%; grade 3, 62,4%; live follicles: 94.3%. Day 14: PB vs CD - Follicle stages: primordial, 3.8 vs 5.7%,NS; primary, 75 vs 86.1%, NS; secondary, 21.2 vs 8.2%, $P < 0.05$; follicle quality: grade I/II, 70 vs 18.9%, $P < 0.01$; grade III, 30 vs 81.1%, $P < 0.01$; live follicles 62.6 vs 35.3%, $P < 0.01$. LDH activity in PB was markedly lower than in CD at all culture times (PB_{14d} 150.5 nmol vs CD_{14d} 233.1 nmol). During 14 days culture, AMH secretion continuously increases in PB (1700 picomol/Vtot) whereas in CD it markedly decreases during culture, falling down at very low values at the end of culture (67 picomol/Vtot). Findings indicate that the increased transport of solutes and dissolved oxygen, and the biomechanical stimulation in our novel dynamic bioreactor are key factors during ovarian tissue culture. Analysis of LDH and AMH levels in spent media confirm that dynamic culture better mantains general tissue health and promote a better functionality of growing follicles.

Limitations, reasons for caution: Although the bovine is considered a reliable model for human folliculogenesis, the study should be validated on human ovarian tissue.

Wider implications of the findings: Poor yield of secondary follicles during organ culture is a limiting step in the in vitro production of mature oocytes from primordial follicles. The use of a newly developed dynamic bioreactor for long-term culture could represent a valuable tool for in vitro multistep folliculogenesis.

P-432 Gonadal function and fertility preservation in girls with Hodgkin lymphoma treated according to the EURONET-PHL-C2 Protocol: the fertility add-on study

K. Drechsel[1], S. Broer[2], A. Beishuizen[3], W.H. Wallaca[4], G. Kaspers[5], M. Veening[6]

[6]Princess Maxima Center and 1.Emma Children's Hospital- Amsterdam UMC- Vrije Universiteit Amsterdam-, Pediatric Oncology, Utrecht and Amsterdam, The Netherlands

Study question: What is the gonadotoxic potential of the EURONET-PHL-C2 treatment protocol for female childhood Hodgkin lymphoma patients, and how frequently are co-treatments to preserve fertility applied?

Summary answer: Treatment-induced amenorrhea (72%) persisted in > 10% of cases. Results on AMH are available by April 2023. Fertility preserving (co-)treatments were applied in 27% of patients.

What is known already: Current treatment for childhood Hodgkin lymphoma (HL) is highly effective with survival rates exceeding 90%. However, HL treatment affects gonadal function and HL survivors were proven to be at risk of premature ovarian insufficiency. In effort to reduce late effects, treatment protocols were adapted and toxic procarbazine was successfully omitted. The current EuroNET-PHL-C2 protocol aims to reduce use of radiotherapy by intensifying chemotherapy. The cumulative dose of cyclophosphamide is increased by 25% in the intensified treatment-arm, the impact of this change in therapeutic protocol on gonadal function is currently unknown. Therefore, a fertility study was incorporated in the EuroNET-PHL-C2 study.

Study design, size, duration: This international, prospective, multicenter cohort study is embedded in the EuroNET-PHL-C2 study, an European phase-3 treatment study evaluating the effectivity of HL treatment with OEPA-COPDAC (OEPA: vincristine sulfate (oncovin), etoposide, prednisolone and doxorubicin (adriamycin); COPDAC: cyclophosphamide, vincristine sulfate (oncovin), prednisone and dacarbazine) versus OEPA-DECOPDAC (DECOPDAC: COPDAC with additional doxorubicin and etoposide) in a randomized setting. In the present fertility add-on study, 205 (104 girls, 101 boys) patients were included between January 2017 and September 2021.

Participants/materials, setting, methods: Female patients, aged <18 years, treated according to the EuroNet-PHL-C2 protocol for classical HL, were recruited across 18 sites (the Netherlands, Belgium, Germany, Austria, Czech Republic). All parents and patients (aged ≥12 years old) provided written informed consent.

Serum AMH levels and menstrual cycle were evaluated over time (at diagnosis, during- and directly after treatment, 2 years post-diagnosis) and compared between OEPA-COPDAC and OEPA-DECOPDAC treatment groups. Moreover, use of available fertility preservation treatments was evaluated.

Main results and the role of chance: In the present analysis, 100 girls were included of whom 88 completed 2 years of follow up. Median age at diagnosis was 15 years (7-18), 8 girls were prepubertal and 92 post pubertal (87% postmenarchal). 17 girls were diagnosed at an early stage of HL (TL1) and 83 in more advanced stages (TL2/TL3, 66% received COPDAC and 33% DECOPDAC). 5 patients (5%) were irradiated in the pelvic area. Of the 46 postmenarchal girls who did not receive hormonal contraceptives during treatment, 33 (72%) experienced treatment-induced amenorrhea, at least 4 (12%) had persisting amenorrhea at 2 years post-diagnosis. 4 girls (22%) who stopped taking hormonal contraceptives after treatment had no (return of) spontaneous cycle. 2 girls (2%) underwent ovariopexy. 4 girls cryopreserved oocytes before treatment and 12 cryopreserved ovarian tissue (OTC). 15 (15%) received GnRH analogues as a co-treatment.

Data on AMH-levels up to 2 years post-diagnosis will be available by April 2023. Change in AMH will be evaluated, comparing number of received chemotherapy-cycles (3/4/6), DECOPDAC versus COPDAC and pubertal stage at time of diagnosis. Additional analyses will be performed to assess the impact of applied fertility preservation methods on gonadal function (i.e. AMH levels after OTC or receiving GnRH agonist).

Limitations, reasons for caution: The current analysis included data up to 2 years post-diagnosis. Potential recovery or late emerging effects of treatment remain unknown. The studied population comprises young girls with diagnosis of HL often concurring with pubertal transition, during which AMH levels naturally rise. SD z-scored will be used to analyze AMH results.

Wider implications of the findings: The fertility add-on study is the first study to prospectively evaluate reproductive markers in children treated for HL. Study results are highly valuable to determine effect of the proposed new treatment regimen for childhood HL on fertility .

O-166 Distinct molecular signatures of successful sperm in situ

J.J. Chung[1]

[1]*Yale University School of Medicine, Dept. of Cellular & Molecular Physiology, New Haven, U.S.A.*

Out of millions of ejaculated sperm, a few reach the fertilization site in mammals. Flagellar Ca2+ signaling nanodomains, organized by multi-subunit CatSper calcium channel complexes, are pivotal for sperm migration in the female tract, implicating CatSper-dependent mechanisms in sperm selection. Here using biochemical and pharmacological studies, we demonstrate that CatSper1 is an O-linked glycosylated protein, undergoing capacitation-induced processing dependent on Ca2+ and phosphorylation cascades. CatSper1 processing correlates with protein tyrosine phosphorylation (pY) development in sperm cells capacitated in vitro and in vivo. Using 3D in situ molecular imaging and ANN-based automatic detection of sperm distributed along the cleared female tract, we demonstrate that spermatozoa past the utero-tubal junction possess the intact CatSper1 signals. Together, we reveal that fertilizing mouse spermatozoa in situ are characterized by intact CatSper channel, lack of pY, and reacted acrosomes. These findings provide molecular insight into sperm selection for successful fertilization in the female reproductive tract.

O-167 The good egg: on the onset of transcription in mouse and human embryos

A. Perry[1]

[1]*University of Bath, Department of Life Sciences, Bath, United Kingdom*

At the moment of union in fertilisation, sperm and oocyte are transcriptionally silent, but little is understood about how transcription initiates in the newly-formed embryo. In this talk, I shall suggest why this fundamental process has remained arcane for so long, and how my lab has sought to unlock its secrets in mouse and human embryos. By combining micromanipulation and single-cell RNA-sequencing, we have revealed a programme of embryonic transcription initiation beginning within four hours of fertilisation in the mouse. The talk will outline our efforts to characterise this initiating transcription, and its conservation in human one-cell embryos. Transcribed genes predict regulation by oncogenic factors, including c-Myc, whose features will be detailed, together with a model suggesting predictive parallels between the onset of embryogenesis and cancer.

O-168 The dark shadow of historical eugenics on reproductive technologies and practices

G. Cavaliere[1]

[1]*King's College London, Dickson Poon School of Law, London, United Kingdom*

Eugenics is often referred to in discussions on the ethics of reproductive technologies. References to the word "eugenics" are often used to draw distinctions between ethically permissible and impermissible technologies, and permissible and impermissible uses of these technologies. While historians have long argued that 20th century eugenics cannot be reduced to a uniform set of practices, references to eugenics in discussions on the ethics of reproductive technologies have proven difficult to eradicate. Some authors stress the similarities between past eugenics and present reproductive technologies (what I define here as "the continuity view") to condemn these technologies. Others focus instead on the differences between past and present (what I define here as "the discontinuity view") to defend reproductive technologies.

In this talk, I canvass the meanings and uses of the word "eugenics" in relation to the permissibility of reproductive technologies and argue that disagreement concerning the value and ethical standing of these technologies originates in divergent views of condemnable and justifiable features of the past. Moreover, I suggest focusing on the reproductive preferences of those accessing fertility treatment as a starting point for any analysis concerning the permissibility of novel reproductive technologies.

O-170 The true impact of fertility problems: insights from the Fertility Network UK and Middlesex University survey

E. Rees[1]

[1]*Fertility Network UK, Wales Co-Ordinator, London, United Kingdom*

Fertility Network UK's survey of approaching 1,300 fertility patients in the UK reveals the devastating toll infertility wreaks on people's mental health, relationships, finances and career. Released at the start of National Fertility Awareness Week 2022, the findings highlight the emotional and financial impact, as well as the lack of information provided by GPs and the limited support options, such as counselling services.

Background: Fertility challenges and the use of assisted conception are increasing. Yet access to funded treatment and associated supports, such as counselling, is often limited, so the financial and emotional impacts of treatment are problematic for many people. In order to examine the impact of fertility challenges and treatment, Fertility Network UK commissioned Middlesex University to conduct a survey to examine the impacts of fertility challenges and treatment in order to update the survey conducted in 2016. The online survey was conducted between April and July 2022 to examine the psychological, emotional and relationship impacts of treatment, funding and support issues, and experiences of combining treatment and work. Specifically, Fertility Network UK gathered information on: - Emotional and psychological impacts of experiencing fertility challenges and of treatment - How it affects relationships with partner, friends, family and colleagues - How it impacts work and career, and how supportive employers are - Access to counselling and other supports - Access to NHS-funded fertility treatment. Fertility Network UK wished the survey to be applicable to a broad range of individuals including those who have fertility challenges but are not having treatment, those who have received or are currently having treatment or who are planning or awaiting treatment, and those who have completed their fertility journey, whether it has been successful or they have had to accept involuntary childlessness.

Key Findings: Mental health

• 4 out of 10 respondents experienced suicidal feelings.

• Approaching half (47%) of respondents experienced feelings of depression often or all the time, while the vast majority (83%) felt sad, frustrated and worried often or all the time.

Finances

• Two-thirds of patients (63%) had to pay for their own medical treatment.

• The average cost of investigations and treatment was £13,750. • Around 1 in 10 couples (12%) spent more than £30,000 and a few (0.5%) spent over £100,000.

Career

• 15% either reduced their hours or left their job.

• Over a third (36%) of respondents felt their career was damaged as a result of fertility treatment, and the majority (58%) felt concerned that fertility treatment would affect their career prospects.

• Only a quarter (25%) reported the existence of a supportive workplace policy

• Less than half (45%) of respondents felt they received really good support from their employer.

Relationships

• The majority of respondents (59%) reported some detrimental impact of fertility problems and/or treatment on their relationship with their partner.

Information & Support

• Approaching half (44%) of respondents sought help from Fertility Network UK, the nation's leading fertility charity.

• Three-quarters of respondents (75%) felt their GP did not provide sufficient information about fertility problems and treatment and 7% were not sure. Less than one-fifth (18%) were satisfied with the information GPs provided.

• The majority of respondents (78%) would have liked to have counselling if it was free. Half of respondents (51%) did have counselling, but most of these (59%) had to fund some of it themselves.

O-171 Psychological support: the light in the darkness of my infertility journey

S. Dumont[1]

[1]*Fertility Europe, Patient association, Saint-Maur des Fosses, France*

Sandrine Dumont shares her own personal patient experience : « my infertility journey started at the age of 32, when I was finally diagnosed with endometriosis after years of pain. I went through one year of natural but monitored baby trials, 4 artificial inseminations, a break-up with my then partner, and 3 IVF with my new partner : these 3 IVF took place during a short period of 5 months. First IVF was in a public hospital, who kicked us out after first IVF failed. Other two IVF took place in a private hospital in Paris, who incidentally diagnosed PCOS : both IVF were also unsuccessful. I was physically and psychologically exhausted, and then decided to take a break from fertility treatments. We expected information and guidance from both fertility centers to help us through this. It never came.

During all these years, we've been appalled with how very few information we were given from all the medical staff. We were never prepared for failure at all. We felt treated badly, even in a rude and sometimes brutal way, by some professionals. Patient care was almost inexistent. We felt like a mere number on a list, not worth being explained anything or just answered our legitimate and simple questions about our own case. We were left alone with our doubts and questions: how could we make an enlightened decision as whether to continue treatments or not, with no information to nurture this decision ?

It seemed an endless dark tunnel with no exit. Then came guilt, loneliness and depression. I searched for external psychological support to help us get through this: this was not easy, since psychological weakness was something to be very ashamed of at the time, in French society. Psychological support turned out to be the light in our darkness. I found a psychiatrist to whom I went weekly for almost two years. This is what it took to heal : accepting failure, accepting my own limits to what I was ready to endure to try to be a mother, accepting to be different from what is expected of a woman in our traditional French society. This therapy was a lifesaver. There also came the association Collectif Bamp, thanks to whom I met a two women in the same situation as me. Knowing I was not alone just changed everything : it was the first day of the rest of my life.

Today, 10 years later, I am now an active member of Bamp association : I try to be there for patients as Bamp was there for me. I share my experience, so people don't feel alone. I advocate pyschological support and real patient care.

SELECTED ORAL COMMUNICATIONS

SESSION 56: OOCYTE PRESERVATION: MISSION ACCOMPLISHED?

Tuesday 27 June 2023 Auditorium 10–12 14:00 - 15:00

Abstract citation ID: dead093.209
O-172 Room and directions for improvement in oocyte cryopreservation

M.J. De Los Santos[1]

[1]*IVI Valencia, IVF Laboratory, Valencia, Spain*

Cryopreservation and more specifically oocyte vitrification has become a before and after in the field of Assisted Reproduction Techniques. Despite great efforts to improve slow oocyte freezing protocols, the levels of reproducibility, survival rates and clinical outcomes achieved by oocyte vitrification have never been reached by any of these old approaches.

However, once this barrier was overcome, new challenges emerged. We must reassert ourselves on issues such as the efficacy, efficiency and safety of a technique that is now fully implemented in IVF laboratories around the world.

Continuos monitoring and improvement as part of the quality management system is mandatory, to keep the the standards of qualilty, identify factors that may affect survival rates and look for room for improvemnt and finetune the protocols.

But also it is important to provide answers to women who wish to preserve their fertility for medical or non-medical reasons. They have key questions such as how many oocytes to store, what the survival rate will be after warming, will the cryopreserved oocytes be able to fertilize and develop as good as the fresh counterparts, how does the number of oocytes used affect the cumulative live birth rate?

Also for women undergoing ART, oocyte vitrification may represent a successful strategy. For example, patients with low response or women at risk of ovarian hyperstimulation, the two sides of the coin, may benefit from oocyte cryopreservation. The former, by storing and accumulating oocytes that allow them to obtain success rates comparable to those of normal responders while avoiding the adverse effects of a low response; the latter, by postponing insemination over time, investing in safety.

Yet embryo vitrification can offer good alternatives to oocyte vitrification so both options can be explored and compared

Trial registration number: XXXX

Abstract citation ID: dead093.210
O-173 Cellular and developmental damage from oocyte cryopreservation

P. Comizzoli[1]

[1]*Smithsonian's National Zoo and Conservation Biology Institute, Veterinary Hospital, Washington, U.S.A.*

Compared to somatic or sperm cells, mammalian oocytes are much more sensitive to cryopreservation mainly because of the large volume, cytoskeleton, and presence of the zona pellucida. Connections with the surrounding cumulus cells also are challenging to preserve in immature oocytes. Besides the genetic and epigenetic information enclosed in the nucleus, oocytes contain organelles and cytoplasmic factors that are necessary for the early embryo development. Therefore, exposure to cryoprotectant and freezing temperatures can easily damage the oocyte's complex cellular structure and developmental competence, which leads to poor success in fertilization, lower embryo quality, and reduced pregnancy rates. Using the domestic cat as a model, our laboratory has studied damages in cumulus-oocyte complexes (immature oocytes) occurring at each step of the cryopreservation process. Specifically, this included the impact of cryoprotectants on microtubules, the effect of osmotic changes on the overall structures, as well as sensitivity of the nuclear chromatin and epigenetic patterns to freezing temperatures. Based on those findings, it has been possible to design mitigating solutions like customized ultra-rapid freezing or vitrification protocols, Laser-warming methods, or post-warming reanimations. New horizons have also been explored to move away from issues and limitations related to cryopreservation. Approaches like storage of oocytes for the long-term at non-freezing temperatures are currently being developed based on encouraging data generated in preliminary studies. For instance, incorporation of trehalose into the oocyte followed by microwave-assisted dehydration can allow to remove enough water while creating a protective trehalose glass compatible with survival and storage at non-freezing temperatures. Interestingly, transcriptomic and proteomic studies have already shown that stresses and damages induced by dehydration versus cryopreservation are different and may be easier to overcome.

O-174 The transition from fertility to maternity care services - a Royal College of Nursing publication

F. Steyn[1]

[1]*Peppy Health, Nursing, London, United Kingdom*

Study question: Is there a need for guidance for nurses and midwives involved in the delivery of care for patients transitioning from fertility service to maternity services.

Summary answer: There is a potential knowledge gap that exists in the transition of care from fertility to maternity services.

What is known already: Once a patient becomes pregnant through fertility treatment in the UK, they are usually discharged out into NHS maternity care services via their general practitioner. This means that the maternity service staff are often unaware of the time it has taken to conceive, fertility treatments and procedures, fertility medications and emotional trauma that the patient has been through already and may not be aware of some of the complexities surrounding the fertility treatment journey.

Study design, size, duration: A project group of 14 key contributors was invited to be part of the publication that included fertility nurses, midwives, early pregnancy specialist nurses and patient representative members. An initial literature review took place and each person contributed from their specialist area. The project to produce the guidance took 9 months of planning, reviewing and meeting to discuss content with a final publication in September 2022.

Participants/materials, setting, methods: An initial literature review of the project subject did not highlight any existing research or publications in this area. A forum governance bid was submitted to produce a 45 page online resource aimed at fertility nursing staff, early pregnancy care staff and maternity services staff. The key project team contributed from their specialist areas and was reviewed by stakeholder groups.

Main results and the role of chance: Pregnancy following fertility treatment can be an exciting, challenging and anxious time for expectant parents. This projects aim was to primarily raise awareness of possible pathways of care for women and others (their partners/support networks) as they travel through fertility treatment and pregnancy, and how they can best be supported by the health care professionals they encounter along their journey. A 45 page online resource was produced and disseminated to fertility, early pregnancy and maternity staff via stakeholder groups and a webinar to launch the publication.

Limitations, reasons for caution: No limitations identified. The publication is available for all staff working in all three areas and provided guidance for all patient pathways including those from the LGBTQIA community.

Wider implications of the findings: No wider implications.

Trial registration number: Not applicable

Abstract citation ID: dead093.212

O-175 The Positive Reappraisal Coping Intervention: how it works in recurrent pregnancy loss

S. Bailey[1], **A. Parkinson**[2], **J. Steer**[2], **J. Boivin**[3]

[1]*University Hospitals Southampton NHS Foundation Trust / University of Southampton, Gynaecology, Southampton, United Kingdom*
[2]*Cardiff University at time of analysis, School of Psychology, Cardiff, United Kingdom*
[3]*Cardiff University, Cardiff Fertility Studies Research Group- School of Psychology, Cardiff, United Kingdom*

Study question: How does the Positive Reappraisal Coping Intervention (PRCI) sustain coping during the early stages of a new pregnancy in women with recurrent pregnancy loss (RPL)?

Summary answer: The PRCI improved psychological well being by sustaining coping and providing psychological respite from the stress of uncertainty.

What is known already: Increased levels of maternal anxiety and uncertainty are common during the early stages of a new pregnancy following RPL when women wait for confirmatory scan of ongoing pregnancy, however psychological support is often limited. The PRCI is a self-administered coping tool developed for uncontrollable and unpredictable situations like waiting, theorised to achieve its benefits by promoting positive feelings alongside negative feelings in unrelenting stressor situations, sustaining coping. It has been shown to have benefits for those awaiting the outcome of fertility treatment and those experiencing RPL by increasing positive emotions, positive appraisals of the situation and emotional quality of life.

Study design, size, duration: We performed secondary analysis of qualitative data from a two-centred feasibility randomised controlled study on the effectiveness of the PRCI for psychological well being of women with RPL. Participants (n = 75) were recruited over a two-year period. Participants for the qualitative component of the study (n = 14), participated in semi-structured interviews exploring their experience of pregnancy following RPL, perception of study methods and the intervention.

Participants/materials, setting, methods: Participants were recruited from the Recurrent Miscarriage Clinic in two tertiary referral hospitals in the UK. Women who had experienced three or more pregnancy losses were eligible to participate. Semi-structured interviews were conducted face to face. Data for the secondary analysis were interview data from the intervention arm of the study, that received the PRCI. Interview transcripts were analysed using NVivo 12 software and the approach of Braun and Clarke (2006).

Main results and the role of chance: This secondary analysis focused on improving understanding of the mechanisms by which the PRCI was perceived to be effective at promoting maternal psychological well being during the challenging early stages of a new pregnancy following RPL. Inductive thematic analysis of the qualitative data identified three themes on which the main theme of 'PRCI sustains coping' was based, namely that PRCI:

- prevented further falling or spiralling down by stimulating questioning of negative thoughts and encouraging time out for oneself
- encouraged an 'I can do this' attitude, acting as a reminder of the positives and stimulating positive thinking in this experience
- was perceived a helpful coping resource to lean on

The study identified that the PRCI was a 'go to' resource in taxing moments of need, conveying benefits to maternal psychological well being by restoring depleted coping resources, stimulating positive coping, and providing psychological respite from the stressor of uncertainty experienced during the early stages of a new pregnancy. There were no apparent downsides of use. These insights are consistent with theory of how positive reappraisal helps people carry on coping in challenging situations.

Limitations, reasons for caution: Since this is a secondary analysis, data was utilised from a study that was not originally designed to investigate the perceived mechanism of the PRCI, and as such the data should be interpreted cautiously.

Wider implications of the findings: PRCI has the potential to be made more widely available as an effective, safe, convenient, and low-cost intervention to provide emotional support in RPL clinics. It might also be a useful coping technique in other clinical contexts where patients/carers experience increased psychological strain because of prolonged periods of uncertainty.

[3]Islamic Azad University- Central Tehran Branch, Department of Sociology, Tehran, Iran
[4]AVAG- University Medical Center Groningen- University of Groningen, Department of General Practice and Elderly Care Medicine- Section Midwifery Science, Groningen, The Netherlands

Study question: What is the knowledge and beliefs of the female students in Tehran universities regarding the oocyte cryopreservation for medical and social reasons?

Summary answer: This study highlighted the positive attitude but insufficient knowledge about medical and social egg freezing and the ideal timing of childbearing in female students.

What is known already: Emerging research indicates that physiologic or pathologic ovarian aging limits the female reproductive capacity and oocyte cryopreservation (OC) is a rapidly evolving branch of reproductive medicine. Given the growing numbers of young women surviving cancer, along with increasing numbers of high educated women postponing childbearing for educational or professional pursuits, there will be a growing demand for egg freezing services to guarantee the pregnancy in near future. Egg freezing can prevent age-related infertility, but it also can cause new potentially ethical and financial problems and the neonatal and maternal risks of childbearing at an advanced maternal age.

Study design, size, duration: Totally, 1279 students from Tehran universities were included in this cross-sectional survey between March and August 2022.

Participants/materials, setting, methods: The survey was distributed through an online forum and advertised on social media groups targeting students in Tehran universities. Childless students in master's and doctoral degrees with the age of ≤ 38 years were included. Bachelor's students were not included. Knowledge and beliefs about medical and non-medical oocyte cryopreservation were assessed through Fertility Preservation Survey (FPS) instrument. To analyze the data, descriptive statistical methods (mean and standard deviation) and analytical statistics (One-way ANOVA) were used.

Main results and the role of chance: The majority of participants were 30-34 years (41.1%, M: 26.38 ± 4.9), not married (77.2%), master's student (77.7%), and hoped to have 2 children in the future (40.5%). Most of participants expected to be "30-34 years" when they become pregnant with their first child (34.4%) and "35-39 years" when they give birth to their last child (39.1%). The students agreed with preserving fertility with medical (93.3%) and social (86.9%) indications and believed medical (95.1%) and social (87.4%) costs of cryopreservation should be covered by health system. Participants believed in the routine providing of information about egg freezing to women of childbearing age as part of regular healthcare visits by health care professionals (95.5%). Women stated if they decide not to use eggs to become pregnant, they would consider donating them for fertility research (67.1%), to a friend or family member with fertility problems (58.1 %) and to infertile couples (42.7%). The overall correct response to knowledge questions was 57.7% which is relatively moderate. The marital status ($P = 0.028$), university faculty ($P = 0.025$) and occupation ($P = 0.048$) were related to knowledge. Married (M: 7.40 ± 1.98) and unemployed students (M: 7.24 ± 2.24) had more knowledge and students of Art faculty had lower knowledge than other faculties (M: 6.36 ± 2.22).

Limitations, reasons for caution: The results would not be generalizable to all female students because the research project's advertisement may have been ignored by students who are not interested in childbearing or it might have been noticed by students who are more interested in childbearing and preserving their fertility.

Wider implications of the findings: The findings are valuable in planning fertility preservation services. The supportive policies for childbearing could be expanded to cover the costs of fertility preservation. Midwives could play an important role in increasing the knowledge about age-related infertility and oocyte cryopreservation and help students in their reproductive life planning.

[7]UMCUtrecht, Gynaecology- fertility, Utrecht, The Netherlands
[8]UMCUtrecht, Gynaecology- pediatric gynaecology, Utrecht, The Netherlands
[9]Princess Maxima Centre, Pediatric surgery, Utrecht, The Netherlands

Study question: How to start an onco-fertility program in a pediatric oncology unit as standard of care

Summary answer: An active onco-fertility program helps to offer the best option for future fertility for pediatric oncology patients. Awareness of fertility risk is necessary.

What is known already: Infertility after treatment for pediatric oncology is an important late effect Of these patients, 25-35 % classify as high risk (HR) for infertility. With the increasing survival chance (>80%) this late effect plays an important role.

Study design, size, duration: An onco-fertility program was started in 2018 with the start of a centralized hospital for pediatric oncology patients (yearly 600 patients) navigated by a nurse-practitioner. The program runs with intense collaboration between the different specialties. All new patients are identified. Fertility-risk is based on the international fertility guidelines.

Participants/materials, setting, methods: All patients are informed on fertility risk by their oncologist. All HR children are additionally counseled by the onco-fertility nurse-practitioner and referred for further counseling to gynecology for ovarian tissue cryopreservation(OTC) or urology for sperm cryopreservation or testicular biopsy (in research setting). Monthly the onco-fertility working-group members discuss difficult cases and research in the field. Survivors have the possibility for fertility consultations.

Main results and the role of chance: Awareness of treatment (chemotherapy, radiotherapy and surgery) on fertility in children has increased from 2018 till now 2023 among oncologists, nursing staff, carers of the child, and the patients themselves. We offer fertility preservation mainly in the high risk for infertility group but also for low risk groups we offer information and counseling . In the outpatient clinic for survivors, there is an increasing number of consults yearly on fertility questions From 2018 till 2022 we saw a fourfold of consults.

The number of high risk for infertility over the years is stable around 30%. Over the years we see an increasing number of patients who have fertility preservation done in time In the girls this increased from 32% in 2018 to nearly 40% in 2022. For the boys it increased from 37% in 2018 to 57% in 2022

Limitations, reasons for caution: This is an ongoing programme in a large pediatric oncology unit in a first world country where this programme is possible. insurance is well organized We realize that in other countries it is much more difficult to run this program

Wider implications of the findings: In 75% of survivors risk of infertility is the most important late effect. Therefore running an onco fertility program at the start of the patient journey offering the patient the best options for fertility preservation will help the patient in future to improve their quality of life concerning fertility issues.

P-793 Human trophoblastic spheroid derived from human expanded potential stem cells (hEPSC) for the identification of adhesion molecules for embryo implantation.

Y.L. Lee[1], H. Ruan[2], A.C.H. Chen[2], S.W. Fong[2], R.H.W. Li[2], E.H.Y. Ng[2], W.S.B. Yeung[2]

[1]The University of Hong Kong, Obstetrics and Gynaecology- School of Clinical Medicine, Hong Kong, Hong Kong
[2]The University of Hong Kong, Department of Obstetrics and Gynaecology- School of Clinical Medicine- Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Study question: Are cell surface proteins on trophoblastic spheroid BAP-EB derived from hEPSC involved in the endometrial epithelial cell attachment?

Summary answer: E-cadherin (CDH1) and Neuropilin-1 (NRP1) are two potential embryonic surface molecules involved in the human implantation process.

What is known already: Study of the mechanisms of human implantation in vivo is challenging. The availability of high-quality human embryos for in vitro research is limited. We have recently derived morula-like hEPSC lines (hEPSC-em) from donated human embryos. Trophoblastic spheroids (em-BAP-EB) derived from hEPSC-em resemble human trophectoderm during the early implantation process. The em-BAP-EBs attach specifically onto receptive endometrial epithelial cells, suggesting its usefulness as human embryo surrogate for studying embryonic surface molecules involving in early implantation process.

Study design, size, duration: hEPSC-em was subjected to embryoid body formation and induced to differentiate into trophoblastic spheroids (em-BAP-EB) for 48h and 72h. Endometrial aspirates were collected from infertile women in their natural cycles 2 or 7 days after LH surge (LH+2/+7). Endometrial epithelial cells (EEC) were isolated and cultured for the attachment assays. Biotin-labelled apical surface proteins on em-BAP-EB were identified by mass spectrometry. Antibody blocking assays were performed to confirm the biological functions.

Participants/materials, setting, methods: The attachment rates of em-BAP-EB onto EEC were compared between pre-receptive (LH+2 day) and receptive (LH+7 day) phases. The differentially expressed apical surface protein on em-BAP-EB-48h and -72h were subjected to plasma membrane proteins (PMP) identification and pathway analysis. The gene and protein expression patterns of the target proteins were analyzed by single cell RNA sequencing (scRNA-seq) and western blotting respectively. The functional roles of the target proteins were studied by antibody blocking during attachment

Main results and the role of chance: The attachment rates of em-BAP-EB-72h onto receptive stage (LH+7, n=17) EEC were significantly higher than those onto pre-receptive stage (LH+2, n=5) EEC. Gene Ontology analysis indicated that the PMP with induced expression levels on em-BAP-EB-72h when compared to -48h (72h>48h) were enriched for "protein binding" and "cadherin binding" in molecular functions, and "cell-cell adhesion" in biological processes. Among them, 28 PMP were trophectoderm-specific. CDH1 and NRP1 were selected for further analysis. Analysis based on a published dataset showed that significantly higher expressions of *CDH1* and *NRP1* were detected in polar trophectoderm as compared to mural trophectoderm of E7 human blastocyst. *CDH1* and *NRP1* were significantly up-regulated in trophectoderm-like em-BAP-EB by scRNA-seq analysis. Live-cell immunocytochemistry demonstrated more intense apical surface expression of CDH1 and NRP1 on em-BAP-EB-72h as compared to -48h. Antibody blocking experiments indicated that pre-treatment of the em-BAP-EB-72h with specific antibody individually against the ectodomains of CDH1 and NRP1 significantly reduced the attachment rates onto receptive endometrial epithelial cells. The data suggested that CDH1 and NRP1 are two potential apical surface molecules essential for blastocyst attachment.

Limitations, reasons for caution: The lack of embryonic compartment in the em-BAP-EB and the absence of other key players like decidualized stromal cells and immune cells in the coculture model might not fully represent the early attachment process. The limited sample size in this study may also limit the interpretation of the data.

Wider implications of the findings: Despite advancement in in vitro fertilization, the success rate remains unsatisfactory. It is not known if embryological factor(s) other than embryo aneuploidy are involved. The current data may suggest the potential roles of CDH1 and NRP1 as non-chromosomal embryological markers of its implantation potential.

P-794 Autologous stem cell-derived mitochondria transfer show therapeutic advantages in human embryo quality rescue

H. Shen[1], Z. Jiang[1]

[1]Peking University People's Hospital, Reproductive Medical Center, Beijing, China

Study question: To fill gaps in the evidence base on the autologous superior mitochondria donor cells, and its therapeutic effect on human embryo development among infertile population.

Summary answer: Autologous urine-derived mesenchymal stromal cells (USC) mitochondria transfer may be an effective strategy to improve embryonic development, especially in infertile females with advanced age.

What is known already: Mitochondria are vital for the initial development of oocytes and embryos. Transferring autologous mitochondria into oocytes of infertile females is a novel and feasible strategy for infertile problems without genomic safety and ethical concerns. Stem cells have biological advantages, but research and evidence in this area are quite scarce.

Study design, size, duration: In vitro fertilization/Intracytoplasmic sperm injection (IVF/ICSI) patients at the Assisted Reproductive Technology (ART) Centre of Peking University People's Hospital (Beijing, China) were divided into young group (<35) and advanced age group (≥35) according to age. Oocytes obtained from each age group were randomly assigned to the conventional ICSI group and the mitochondria ICSI group.

Participants/materials, setting, methods: Mitochondrial morphology, mitochondrial DNA (mtDNA) copy number, mitochondrial activity, metabolic capacity are analyzed among autologous adipose, marrow, urine-derived mesenchymal stromal cells (ADSC, BMSC and USC) and ovarian germline granulosa cells (GC). Whole mitochondrial genome sequencing was performed to validate mtDNA biosecurity. The effect of mitochondrial transfer was evaluated by human early embryonic morphology, euploidy, mitochondrial content, mitochondrial membrane potential (MMP), cytosolic reactive oxygen species (ROS) and Ca^{2+} levels.

Main results and the role of chance: Among many types of human primary cells, urine-derived mesenchymal stromal cells (USC) demonstrate a non-fused spherical mitochondrial morphology and low oxidative stress status, which resembles the oocyte stage. Moreover, USC mitochondrial content, activity and function are all higher than other cell types and less affected by age, and it also exhibits a biphasic metabolic pattern similar to the pre-implantation stage of embryonic development. After the biosafety identification of USC mitochondrial genome, human early embryos after USC mitochondria transfer showed improvements in mitochondrial content, activity, and cytoplasmic Ca^{2+} levels. Further, aging embryos also showed improved

embryonic morphological indicators, euploidy rates, and oxidative stress status.

Limitations, reasons for caution: Our study is an in-vitro basic research on human early embryos, further basic mechanisms and clinical trials are still needed to confirm its clinical therapeutic results.

Wider implications of the findings: Autologous USC mitochondria transfer provides evidence and possibility for the autologous treatment in the infertile females without invasive and ethical concerns.

P-805 Gene expression of human endometrial organoids hormonally treated in vitro for 28 days

Y. Jiang[1,2], M. Varshney[3], A. Reyes Palomares[1,2], J. Inzunza[3], K.A. Rodriguez-Wallberg[1,2,4]

[1]Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden
[2]BioClinicum, Laboratory of Translational Fertility Preservation, Stockholm, Sweden
[3]Karolinska Institutet, Department of Biosciences and Nutrition, Stockholm, Sweden
[4]Karolinska University Hospital, Department of Reproductive Medicine- Division of Gynecology and Reproduction, Stockholm, Sweden

Study question: Does gene expression of human endometrial organoids (EO) mimic the *in vivo* response to a 28- days substitutive hormonal treatment?

Summary answer: Gene expression profile of human EO exposed to 28-day hormone treatment showed correspondence with the phases of the menstrual cycle *in vivo*.

What is known already: The recent development of human EO demonstrated their translational potential for reproductive medicine. Current studies testing functional response to hormones of EO are based on short-term responsiveness to estrogen (E2), progesterone (P4) and differentiation factors up to 10 days. It is unknown how organoids can be used to faithfully reproduce and/or model a complete menstrual cycle of 28 days. High-throughput analyses on endometrium have identified specific markers available for characterizing differentiation and functional aspects related to secretory activity and receptivity to implantation.

Study design, size, duration: Experimental research was carried out including 4 endometrial biopsies donated by women with normal endometrium function, recruited at an academic center for assisted reproduction between 2022-06-15 to 2022-07-28. These endometrial biopsies were processed for organoid derivation and culture. The EO were hormonally treated *in vitro* and analyzed for gene expression.

Participants/materials, setting, methods: Human endometrial biopsies were enzymatically digested to isolate endometrial glands, embedded in matrigel and cultivated in a spinning bioreactor to achieve organoid formation. Thereafter EO were treated as following: 1) E2: (day 0–28); 2) E2 + P4: E2 (day 0–28), P4 (day 14–28); 3) E2 + P4 + dibutyryl cyclic Adenosine monophosphate (dbcAMP): E2 (day 0–28) + P4 (day 14–28) + dbcAMP (day 14–28) or 4) control group.

Main results and the role of chance: A total of 10 markers were selected for functional analysis and 3 showed a pattern of interest. The target gene expression included Forkhead box O1 (FOXO1), involved in regulating endometrium receptivity in human; progesterone associated endometrium protein (PAEP), a major protein in glandular endometrium secretions; and secreted phosphoprotein 1 (SPP1), an extracellular cytokine that increases in endometrium during the receptive phase.

Gene expression of FOXO1, PAEP and SPP1 showed a significant increase in the organoids exposed to complete hormonal cycle, compared to controls. PAEP and SPP1 gene expression was lower up to day 21 but upregulated to 15-fold relative to non-treated group by day 28. This pattern recapitulates a similar response to the physiological conditions *in vivo* in the human endometrium. Although gene expression patterns followed similar trends, individual biopsies had slight variations in gene expression along 28-day hormone treatment.

The 28 day-hormone treatment can stimulate EO for recapitulating histological and functional aspects. The dynamics resembled a timely correlation with gene expression changes accounting for some specific markers mostly involved in receptivity, and thus reinforcing the potential application of EO for further research purposes.

Limitations, reasons for caution: In vitro organoid culture conditions may have some influence over responsiveness and gene expression that requires further optimization to reproduce uterine environment in vitro and for other conditions related to infertility in a completely defined culture system.

Wider implications of the findings: Our findings enable the opportunity to expand experimental research over endometrial disorders affecting different stages of the menstrual cycle and also to improve research related to embryo-endometrium interactions.

Trial registration number: This research has been funded by grants from The Swedish Cancer Society, The Swedish Childhood Cancer Foundation, The Cancer Research Funds of Radiumhemmet, The Swedish Cancer Association BRO, the Stockholm County Council (CIMED) and Karolinska Institutet.

P-803 3D human endometrium from noninvasively retrieved primary endometrial cells is a reliable model to mimic the implantation window

F.P. Luongo[1], I. Ortega Baño[1], G. Morgante[1], A. Luddi[1], P. Piomboni[1]

[1]University of Siena, Molecular and developmental medicine, Siena, Italy

Study question: Can human endometrial organoids (hEOs) from a noninvasive source (menstrual blood-MB) mimic the physiology of a receptive endometrium

Summary answer: Endometrial organoids from MB functionally respond to stimuli and express markers of receptivity and can be modulated.

What is known already: 3D models are considered a new step in promoting precision medicine and an advanced tool for studying endometrial biology, endometrial-associated diseases, and understanding the complex mechanisms that comprise endometrial-embryo crosstalk. So far, both 2D and 3D models are usually obtained from endometrial biopsy. The recent discovery of molecules crucial for successful embryo implantation has offered researchers valuable insights in this field. However, important questions about the molecular mechanisms that drive this process remain to be deciphered.

Study design, size, duration: hEOs are usually obtained from endometrial biopsy, in this case a noninvasive source(MB) was used to isolate endometrial epithelial (Ep) and stromal (hESC) cells. The hEOs were generated to study the morphological changes that occur in vivo during the menstrual cycle, particularly in the window of implantation (WOI). The hEOs obtained from MB were exposed to hormones treatments to mimic WOI and were also treated with the progesterone blocker mifepristone to reverse the decidualization process.

Participants/materials, setting, methods: 3D hEOs were prepared from 6 healthy volunteers and cultured for 4 days in expansion medium supplemented with 10^{-8} M E_2 + 10^{-6} M P_4 and 500 uM cAMP. As a control, hEOs were treated with the progesterone blocker mifepristone to reverse the decidualization process. Finally, hEOs were washed with PBS and fixed for immunofluorescent staining or for scanning-electron-microscopy (SEM) or stored at -80 °C for gene expression analysis.

Main results and the role of chance: In this study, we were able to establish a reliable 3D model using both epithelial and stromal cells with a less invasive approach to mimic the mid-secretory phase. Immunofluorescence staining of vimentin (marker of stromal cells) and cytokeratin 19 (marker of epithelial cells) confirmed that organoids are formed by both Ep and hESCs. Using SEM, we closely observed the luminal surface of hEOs in proliferative phase, where the inner side of Ep cells was characterized by the presence of pinopods, a specific marker of the implantation window. In addition, hEOs

express PP14, an implantation marker that has been shown to be significantly up-regulated during WOI. Finally, the expression of FKBP5, regulated by cAMP, and ZBP16, regulated by progesterone, increased significantly during decidualization, while their expression was up-regulated at dawn by mifepristone, a progesterone blocker, thus confirming that hEOs are an effective model of WOI.

Limitations, reasons for caution: All results need to be validated in a larger cohort and further implemented with other cell types (e.g., endothelial and immune cells) to implement this model for drug testing and therapy

Wider implications of the findings: Effective and reliable modeling of embryonic implantation is needed to mimic the cascade of molecular events that occurs in vivo. This model can be used for personalized medicine without the invasiveness of biopsy.

O-178 Conventional IVF results in better embryo development when compared with ICSI in patients without severe male factor

M.D. Cuquerella[1], S. Rafael[1], S. Veganzones[1], M. Vidaurreta[1], M.I. Calventus[1], I. Cristobal[1]

[1]*Hospital Clinico San Carlos, Reproduction Unit, Madrid, Spain*

Study question: Which fertilisation technique offers better embryo development results in patients without severe male factor?

Summary answer: Conventional IVF offers better results regarding embryo development than ICSI in patients without male factor when applying both techniques in the same cohort of oocytes.

What is known already: ICSI was originally indicated for severe male factor. Nevertheless, it is currently used for many other indications so that it has become the most used technique. One of the reasons for the use of ICSI is the fear of a fertilisation failure when using conventional IVF (cIVF).

We have to consider that ICSI is more expensive and invasive. For this reason, it is important to know whether there is a justification to use it in these cases.

Study design, size, duration: It is a randomized prospective study where 68 IVF/ICSI cycles were analysed. The study comprised 812 oocytes and 469 embryos and was conducted from January to December 2022 in the Assisted Reproduction Unit of a tertiary hospital.

In each cycle, we performed a mixed technique using cIVF and ICSI in the same cohort of oocytes.

MII rate, fertilisation rate and embryo development were analysed.

Participants/materials, setting, methods: All consecutive cycles with at least 6 fresh oocytes and semen parameters suitable for cIVF were offered to participate.

In each cycle, oocytes were divided into two groups in order of collection and the fertilisation technique (cIVF or ICSI) was randomly assigned for each group.

All the embryos were cultured to blastocyst stage.

Data of maturity, fertilisation and embryo development were individually registered for every oocyte.

Data were statistically analysed by applying multilevel regression models.

Main results and the role of chance: The patients average age was 36.3 ± 3.0 (28 to 40) and the number of oocytes per cycle was 11.9 ± 5.1 (6 to 26).

396 oocytes (48.8%) were allocated to cIVF group and 416 (51.2%) to ICSI group.

The percentage of mature oocytes was significantly higher in cIVF group than in ICSI group (88.9% vs 81.5%, $p = 0.017$), which is consistent with the later assessment of maturity in cIVF.

There were no statistically significant differences between cIVF and ICSI groups in terms of fertilisation rate (59.6% vs 56.0%) and high-quality blastocyst rate (A+B) (9.3% vs 8.7%) when analysed per oocyte.

We observed clinical but not statistical differences in blastocyst rate per oocyte (30.6% cIVF vs 23.6% ICSI, $p = 0.09$). However, blastocyst rate per fertilised oocyte showed statistically significant differences (51.3% cIVF vs 41.6% ICSI, $p = 0.047$).

Additionally, we found statistically significant differences between cIVF and ICSI in the rate of usable blastocysts (transferred or cryopreserved) per oocyte (26.3% vs 18.3%, $p < 0.01$) and per fertilised oocyte (44.1% vs 32.2%, $p < 0.01$).

In 57.8% of the cycles, the best blastocyst was obtained by cIVF and in 42.2% by ICSI.

Fertilisation failure was observed in 3 patients with cIVF and 1 patient with ICSI. All of them had ≤4 mature eggs.

Limitations, reasons for caution: This study includes the 68 patients who met the recruitment requirements until this moment. It is a part of a wider work, which will analyse a higher number of oocytes and pregnancy and perinatal outcomes. For this reason, the sample size is a limitation to the interpretation of the results.

Wider implications of the findings: Our findings encourage the use of cIVF when there is no severe male factor. Considering that cIVF is cheaper and less invasive than ICSI, the exclusive use of ICSI in these patients does not seem to be justified according to our results.

Trial registration number: not applicable

O-179 Fertilization topologies that occur seldom or not at all in nature give rise to distinct functional classes of mouse embryos

M. Boiani[1], G. Fuellen[2], R. Halabian[3], W. Makalowski[3], T. Nolte[1], Y. Suzuki[4], S. Israel[1]

[1]*Max Planck Insitute for Molecular Biomedicine, Department of Cell and Tissue Dynamics, Münster, Germany*

[4]*University of Tokyo, Department of Computational Biology and Medical Sciences, Kashiwanoha Kashiwa, Japan*

Study question: Would new embryo properties emerge if fertilization was imposed on oocytes in regions, such as the animal pole, where it does not take place naturally?

Summary answer: Oocyte fertilization at the animal pole, vegetal pole or equator results in 2-cell embryos with distinguishable transcriptomes and functional peculiarities.

What is known already: There is fertilization bias in embryos used in basic and clinical research, because: 1) sperm–oocyte fusion hardly occurs at the surface above the meiotic spindle – the animal pole; 2) the region opposite the spindle - vegetal pole - is poorly accessible to sperm due to tiny perivitelline space. These regions are also avoided during intracytoplasmic sperm injection (ICSI) for fear of damaging the spindle or losing the sperm nucleus into the 2nd polar body. Pole materials are held non-essential for mouse development, but this conclusion relies on the 2nd polar body, which is an unreliable topological marker.

Study design, size, duration: Oocytes were rotated using a micromanipulator fitted with Nomarski optics, using the meiotic spindle as a landmark. Between 9:30 and 10:30 am single sperm heads were microinjected (ICSI) at the animal or vegetal pole (treatments) vs. the naturally prevalent equatorial region (control). This way two fertilization topologies and possibly also two classes of zygotes were created that are otherwise seldom or not at all represented in natural fertilization, in vitro insemination or conventional ICSI.

Participants/materials, setting, methods: Metaphase II oocytes were collected from 8-week-old B6C3F1 mice stimulated with 10 I.U. eCG+hCG. Sperm heads from a single batch of cryopreserved CD1 semen were deposited via ICSI in the cortex at the animal pole, vegetal pole or half-way between poles i.e. equatorially. Zygotes were cultured in KSOM(aa) and analyzed (triplicate or more) for: cleavage rates, transcriptomes at the 2-cell stage (RNAseq), blastocyst germ layers (immunostaining for trophectoderm, primitive endoderm, epiblast), and postimplantation development.

Main results and the role of chance: Although full development was supported irrespective of ICSI site, embryos clustered by site, as revealed by single-cell RNAseq of 21, 21 and 13 two-cell embryos whose oocytes were fertilized at the animal pole, vegetal pole or equator, respectively. When examining the sister blastomeres together, 462 genes of the shared transcriptome were differently expressed between ICSI sites, with the equatorial class contributing most to the difference (adj.p<0.05, Wilcoxon test). This was true also when examining the sister blastomeres separately: inter-blastomere differences of the equatorial class exceeded those of the pole classes (72% vs. 14% of differently expressed genes). Ontology analysis of the differently expressed genes using *Enrichr* pointed at the endomembrane system – an acquaintance of oocyte polarity studies (PMID 10545249; PMID 29746690). Follow-up of 2-cell embryos to blastocysts revealed that sister blastomere contribution to each germ layer was less balanced in the equatorial class, as measured by linear correlation of cell numbers (e.g. equatorial R^2=0.00 vs. polar R^2>0.23 for the epiblast). Summing up, it is difficult to reconcile these data with a mainstream view that fertilization at the animal pole is harmful. Rather they support that the topology of fertilization defines functional classes of 2-cell embryos with distinguishable transcriptomes.

Limitations, reasons for caution: This is an animal study. Mouse ICSI uses mercury-loaded piezo-driven needles, human ICSI does not. The higher consistency of using the one and same batch of cryopreserved spermatozoa was traded off against lower developmental rates. Single-cell resolution posed a limit on RNAseq depth. Results need confirmation in other mouse strains.

Wider implications of the findings: The higher blastomere similarity observed after ICSI at the vegetal pole compared to ICSI at the equator is not consistent with the prevalent model of first zygotic cleavage that is driven by the topology of the two apposing pronuclei.

Trial registration number: not applicable

O-180 What is the true potential of 1PN embryos? A report on utilisation and live birth rates following PGT-A and biparental testing

C. Ussher[1], S. Holden[1], M. Bowman[2], S. McArthur[3]

[1]*Genea, Embryology, Melbourne, Australia*
[2]*Genea, Medical Director, Sydney, Australia*
[3]*Genea, Scientific Director, Sydney, Australia*

Study question: What is the developmental potential of monopronuclear (1PN) embryos, and does allowing their use only after confirming biparental inheritance offer a clinical solution for them?

Summary answer: 1PN embryos demonstrate clear utilisation, euploidy, and live birth rates, that warrant their routine culture, and use following biparental inheritance testing, in the clinical setting.

What is known already: Embryos only displaying a single pronuclei (1PN) are widely regarded to be abnormal and not suitable for clinical use. It is therefore common practice to discard these embryos following fertilisation check. However, 1PN embryos have shown the ability for normal blastocyst development, albeit at a decreased rate, and the ability to produce live births.

To bridge the gap between discarding an "abnormal" 1PN embryo, and the knowledge that it can result in a live birth, our clinic utilises PGT-A with biparental inheritance testing to assess the fitness of a 1PN embryo for transfer.

Study design, size, duration: A retrospective analysis was performed of 5010 1PN embryos derived from IVF (2612) or ICSI (2398) insemination at Genea clinics across Australia between January 2017 and November 2022.

Blastocyst development, euploidy, parental inheritance, pregnancy, and live birth rates were analysed.

Participants/materials, setting, methods: Embryos were defined as being 1PN by the appearance of one pronuclei at fertilisation check 16-18 hours post insemination. Time lapse footage was reviewed on day 3 of culture to eliminate the late appearance of a second pronucleus. Suitable embryos underwent trophectoderm biopsy for PGT-A and biparental inheritance testing. Only euploid embryos with confirmed biparental inheritance were available to patients for frozen embryo transfer.

Main results and the role of chance: 1PN embryos derived from ICSI insemination were found to have a significantly lower blastocyst development potential of 17.4% compared to 33.7% for IVF embryos ($p < 0.0001$). The utilisation rate was also significantly lower at 8.1% for ICSI vs 21.2% for IVF ($p < 0.0001$).

The IVF embryos showed a higher rate of euploidy following PGA-T testing, 50.9% for IVF vs 37.9% for ICSI ($p < 0.0001$).

Uniparental inheritance, an indication the 1PN appearance was caused by parthenogenesis, was only observed in 6.7% of the total embryos tested, with IVF embryos having a considerably lower rate of 1.8% vs 20.5% for ICSI ($p < 0.0001$).

There was no significant difference between the 2 groups for pregnancy rate or live births, following single embryo transfer, with 58.6% for IVF vs 62.9% for ICSI ($p = 0.6$) and 39.6% for IVF vs 45.7% for ICSI ($p = 0.5$) respectively. These levels were comparable to normally fertilised (2PN) euploid embryos across Genea clinics in the same time period. During the study period there have been 175 1PN embryos transferred that has resulted in 69 live births from embryos that otherwise would have been discarded.

Limitations, reasons for caution: The use of timelapse imaging from the time of insemination for ICSI embryos, as opposed to 16-18 hours post insemination for IVF embryos may play a role in the type of 1PN embryos that are being identified in each group.

Wider implications of the findings: This study demonstrates that not all 1PN embryos are abnormal and their routine use in the clinical IVF lab in conjunction with appropriate testing should be re-evaluated.

O-181 Utilisation of monopronucleated (1PN) embryos and potential clinical benefits for patients

S. Perry[1], D. Wells[2], S. Batha[3], D. Babariya[2], C. Moore[3], J. Nicopoullos[3]

[1]*Lister Fertility, Embryology, London, New Zealand*
[2]*Juno genetics, Genetics, London, United Kingdom*
[3]*Lister Fertility, Embryology, London, United Kingdom*

Study question: Is it beneficial to culture 1PN embryos for clinical use?

Summary answer: Culturing 1PN embryos to blastocyst for potential clinical use is beneficial to all patients, especially those with low prognosis.

What is known already: 1PN embryos are those with only a single pronucleus visible at the time of fertilisation check. It is generally assumed that such embryos are haploid, having only 23 chromosomes in each of their cells. Given that haploid embryos are not viable, current guidelines recommend only transfering embryos where two pronuclei are visualised. Embryo biopsy at the blastocyst stage, followed by testing with next-generation sequencing (NGS), combined with analysis of DNA polymorphisms, can reveal whether 1PN embryos are truly haploid, or whether normal fertilsation has occurred. Previous studies have shown that in some cases a diploid chromosome number may be present.

Study design, size, duration: A new clinical policy was put into practice to culture all 1PN embryos to day 5/6. This is an ongoing study initiated in April 2022. The data reported are from an eight month period, up until December 2022. During this time, we cultured 288 1PN embryos from 203 patients. Trophectoderm biopsy specimens were shipped to a specialist genetics laboratory where they underwent PGT-A using a method that assesses chromosome copy number and polymorphisms in tandem.

Participants/materials, setting, methods: If embryos were assessed at fertilisation check and found to be 1PN they were not discarded, but rather they were maintained in culture. If any such embryos successfully produced a blastocyst the patients received counselling from their fertility consultant and an embryologist, giving them the options to either go ahead with transfer (only IVF derived), have the embryos genetic status clarified using PGT-A, freeze without testing, or to discard the embryo.

Main results and the role of chance: Of the 288 1PN embryos cultured (IVF and ICSI derived) 85 displayed signs of blastulation (29.5%). 134 of these were derived from ICSI with 20 forming blastocysts (14.9%). 154 were derived from IVF with 65 forming blastocysts (42.2%). Three IVF derived 1PN embryos have been transferred. Currently one is an ongoing singleton pregnancy, one is an ongoing twin pregnancy and the third has resulted in a live birth. 35 embryos were biopsied and underwent genetic testing to confirm their ploidy status. Six of these were ICSI derived, four of which were found to be haploid and two diploid. The other 29 tested embryos were derived from IVF. Of these, 27 were found to be diploid (93.1%) and two were shown to be triploid (6.9%). None were confirmed as haploid. Traditionally, PGT-A methods using NGS examine relative chromosome copy number, but in cases of haploidy/triploidy all of the chromosomes are decreased/increased in number, meaning there is no change in the relative number of individual chromosomes. We established embryo ploidy status using an advanced PGT method, genotyping thousands of polymorphisms scattered across the genome, which are essential for accurate diagnosis of haploidy/triploidy.

Limitations, reasons for caution: The sample size for genetically tested ICSI derived 1PN's is currently too small to clearly determine whether culture and testing of these embryos is beneficial to the patient. Patients who decided to transfer an embryo categorised as 1PN were made fully aware of the potential risks in doing so.

Wider implications of the findings: These findings show that the culture of 1PN embryos is clinically beneficial to a large number of patients, especially those with poor prognosis who would otherwise have had a failed cycle. Genetic testing demonstrates that IVF derived 1PN embryos that reach the blastocyst stage are likely to have fertilised normally.

[3]*University of Urbino "Carlo Bo", Department of Biomolecular Sciences, Urbino, Italy*

Study question: What are the developmental competence and clinical value in ICSI cycles of retrieved metaphase-I oocytes matured in vitro (rescued-MI) to the metaphase-II (MII) stage?

Summary answer: Rescued MI-oocytes showed lower developmental but similar post-implantation competence than their sibling MII-oocytes, thereby contributing to a + 9.5% relative-increase in the cumulative-live-birth rate per completed-cycle.

What is known already: MI-oocytes are typically excluded from ICSI. Nevertheless, some authors reported their use in cancer or poor responder patients. On average, 15-20% of the oocytes retrieved in IVF are immature, but 45% of them may mature within a few hours of culture. These rescued-oocytes showed lower developmental, chromosomal and reproductive competence. Regardless, they might be valuable for some patients. To date, most of the studies were conducted including patients using own oocytes, thus implicitly involving the bias of infertility and poor prognosis. Here we aimed at outlining the clinical value of rescued-MI oocytes in the context of egg donation cycles.

Study design, size, duration: Observational study conducted at a private IVF center including 284 fresh oocyte donation cycles (Jan-2020 to Dec-2021). Two hours after oocyte-retrieval, all MI-oocytes identified after denudation were cultured for 1-2 additional hour(s). If reaching the MII-stage, they were inseminated via ICSI with ejaculated sperm, as for sibling MII-oocytes. Single culture in continuous media was conducted. MI- and MII-derived embryonic cohorts were monitored and compared. One-hundred-fifty-three cycles in the same period had no MI-oocyte available.

Participants/materials, setting, methods: Two-hundred-eighty-four cycles were conducted from 272 recipients (42.1 ± 4.0 years) with fresh oocytes retrieved from 215 donors (25.5 ± 5.0 years). All sperm samples were ejaculated (42.3% fresh; 15% oligoasthenoteratozoospermic). The number of MI- and MII-oocytes after denudation was 2.2 ± 1.3 (range:1-7) and 7.5 ± 1.6 per cycle, respectively. 1.7 ± 1.2 (0-6) MI-oocytes matured in vitro (rescue-rate: 78.1 ± 33.4%) and were inseminated. Embryological data were compared between sibling MI- and MII-derived cohorts. Clinical data and relative contributions of MI-oocytes were also reported.

Main results and the role of chance: The mean fertilization rate per cohort of inseminated MI- and MII-oocytes were 54.3 ± 43.0% and 74.4 ± 18.1%, respectively (paired t-test<0.01). The mean blastulation rate per cohort of MI- and MII-derived zygotes were 53.1 ± 44.4% and 59.1 ± 25.9%, respectively (paired t-test=0.1). Overall, 0.5 ± 0.7 (0-4) MI-derived blastocysts were obtained adding up to the 3.2 ± 1.7 MII-derived ones, thereby resulting in a + 20.8 ± 40.1% (0 to + 300%) relative increase per cycle. Overall, 268 (94%), 247 (89.7%), and 188 (66.2%) cycles had ≥1, ≥2 and ≥3 MII-derived blastocyst(s), respectively. These rates showed a + 1.1% (N = +3), +4.9% (N = +12) and +7.4% (N = +24) relative increase due to MI-derived blastocysts use. To date, 19 out of 63 MI-derived blastocysts transferred resulted in a live-birth (30.2%, 95%CI 19.6-43.2) versus 124 out of 399 MII-derived ones (31.1%, 95%CI 26.6-35.9; p = 0.99). We reported 4 miscarriages out of 27 clinical pregnancies (14.8%, 95%CI 4.8-34.6) versus 38 out 162 (23.5%, 95%CI 17.3-30.9, p = 0.45), respectively. To date, 70% (N = 199/284) of the cycles was concluded, with a cumulative-live-birth-rate of 61.3% (N = 122/199). This rate showed a + 9.5% (N = +18) relative increase due to MI-derived blastocysts use. Among 85 non-completed cycles, 19 (22.4%) have MI-derived blastocysts still available.

Limitations, reasons for caution: Retrospective study. A cost-effectiveness analysis is warranted, especially because MI-oocytes clinical use involves additional workload and costs. 31% (N = 44/140) of patients with ≥1 live-birth have supernumerary cryopreserved MI-derived blastocysts. Many cycles are not concluded. Gestational/perinatal outcomes were not reported. More data with own eggs and/or including chromosomal testing are needed.

Wider implications of the findings: Rescuing MI-oocytes might increase the number of blastocysts available per cycle, and possibly the cumulative-live-birth-rate. Nevertheless, this practice involves a higher workload and the production of more supernumerary blastocysts. Mostly poor prognosis couples might benefit from their use; therefore a couple-specific decision-making process is desirable.

[5]Chaim Sheba Medical Center & Herzliya Medical Center, In Vitro Fertilization Unit- Department of Obstetrics and Gynecology- Tel Aviv Univserity, Ramat Gan, Israel

Study question: Can an Artificial Intelligence (AI) algorithm accurately predict the number of total\mature (MII) oocytes retrieved during an antagonist protocol cycle for different trigger days.

Summary answer: AI algorithm can accurately predict the number of total and MII oocytes for three different trigger days in an antagonist protocol.

What is known already: Two recent studies used machine learning prediction models for determining the number of MII oocytes retrieved during ovarian stimulation. These studies predicted MII with mean absolute error (MAE) 2.87-3.11 and R2 0.62-0.64. However, currently no studies show results for predicting total and MII oocytes two days in advance.

Study design, size, duration: The data used for developing this algorithm consists of 9,622 antagonist protocol cycles performed in a large center serving over 50 physicians, between August 2017 and November 2022. This dataset contains a subset of 5,517 cycles with information about the maturity of each retrieved oocyte representing ICSI cycles and egg freezing (MII dataset).

Participants/materials, setting, methods: Two sets of prediction models were developed using XGBoost, to estimate the number of total and MII oocytes, each with three individual predictors for different possible trigger days: today, tomorrow, in two days. Parameters used include estradiol and LH levels, follicles' size, stimulation days, gonadotropin dosage, and patients' characteristics. Accuracy of the model was evaluated by comparing the predictions to the actual values on 20% of the data that was reserved as a test set.

Main results and the role of chance: The accuracy of the models for the total number of oocytes evaluated using the entire test set, while the models for the number of MII oocytes evaluated using the MII dataset test.

The performance of the prediction models for the number of oocytes: (1) trigger today, R2=0.72, MAE=2.59 (2) trigger tomorrow, R2=0.66, MAE=2.95 (3) trigger in two days, R2=0.64, MAE=3.12.

Of the prediction models for the number of MII oocytes: (1) trigger today, R2=0.68, MAE=2.24 (2) trigger tomorrow, R2=0.62, MAE=2.53 (3) trigger in two days, R2=0.59, MAE=2.54.

Further evaluation was done on a refined subset, excluding cycles with a very large difference between the number of follicles in the last ultrasound and the number of oocytes retrieved (~10%).

The performance of the prediction models for the number of oocytes: (1) trigger today, R2=0.81, MAE=2.14 (2) trigger tomorrow, R2=0.73, MAE=2.42 (3) trigger in two days, R2=0.69, MAE=2.77.

Of the prediction models for the number of MII oocytes: (1) trigger today, R2=0.74, MAE=2.03 (2) trigger tomorrow, R2=0.66, MAE=2.25 (3) trigger in two days, R2=0.62, MAE=2.38.

Limitations, reasons for caution: To ensure accurate predictions, it is important to only provide predictions on days when a trigger can be performed. Thus, an outlier detection mechanism is required to identify predictable days. This requirement is a limitation when using the prediction models for the number of total or MII oocytes in real-time.

Wider implications of the findings: Estimating the number of oocytes retrieved for different trigger days may assist in selecting the optimal trigger day and potentially improving outcomes. Additionally, if the estimated number of oocytes retrieved for different trigger days are similar, it may provide more flexibility in choosing the trigger day.

O-184 Validation of a model capable of estimating the minimum number of mature oocytes needed to obtain at least one euploid blastocyst regarding female age

C. Rodríguez Varela[1], E. Labarta[2], J.M. Mascarós[3], E. Bosch[2]

[1]Medical Research Institute La Fe, IVI Foundation, Valencia, Spain
[2]IVIRMA Valencia, Reproduction, Valencia, Spain
[3]IVI Foundation, Research Support and Management Unit, Valencia, Spain

Study question: Which is the minimum number of mature oocytes needed to obtain at least one euploid blastocyst regarding female age in In Vitro Fertilization (IVF) treatments?

Summary answer: The validated model estimates with a 74% accuracy the probability of having one euploid blastocyst regarding the number of mature oocytes and female age.

What is known already: Female age is significantly and directly related to embryo aneuploidy rates, thus lowering the chances of success in IVF treatments. The current delay in motherhood has led to a large proportion of women of advanced maternal age seeking infertility treatment. The aim of the present study is to determine the number of metaphase II (MII) oocytes needed to obtain at least one euploid blastocyst regarding female age. This information will help to decide the best strategy for each patient, taking also into account other variables such as ovarian reserve, semen quality and oocyte quality.

Study design, size, duration: Retrospective analysis of IVF cycles with preimplantational genetic testing for aneuploidies (PGT-A) performed over the last 5 years in an infertility clinic in Spain, from January 2017 to March 2022.

Participants/materials, setting, methods: Patients undergoing an IVF cycle in an infertility clinic with own or donated oocytes, regardless semen origin. Only trophoectoderm biopsies performed on day 5 or 6 of development and analyzed using Next Generation Sequencing (NGS) were included. PGT-A was used for reasons such as advanced maternal age, implantation failure and recurrent miscarriage. PGT-A cycles due to a known abnormal karyotype were excluded. Endpoints were analized using binary logistic regression models.

Main results and the role of chance: A total of 3840 IVF-PGT-A cycles meeting the inclusion criteria were performed in the study period. Of them, 939 cycles were discarded due to the absence of any biopsied/analyzed embryo (final sample size=2901). A model for the probability of having at least one euploid blastocyst (pEB) regarding female age and the number of MII oocytes retrieved was created with 80% of the sample (n = 2320) and validated in the remaining 20% (n = 581). The validation of this model showed that it was capable of estimate with an accuracy of 73.88%. The pEB was directly related to the number of MII oocytes retrieved (odds ratio (OR) 1.130, confidence interval (IC) 95% (1.110-1.150); $p < 0.001$), but indirectly related to female age (OR 0.751, IC95% (0.725-0.778); $p < 0.001$). The ROC curve showed a significant predictive value of the number of MII oocytes (area under the curve (AUC):0.8041 (0.7882-0.82)) for this model. A mathematical formula was created for the calculation of pEB using this model. The number of MII oocytes needed for a pEB of 75% regarding female age (female age:number MII) was 35:6, 36:9, 37:12, 38:15, 39:18, 40:21, 41:24, 42:27, 43:30, 44:32, 45:35, 46:38, 47:41, 48:44, 49:47, 50:50.

Limitations, reasons for caution: The main limitation of this study is its retrospective design. In addition, it's important to keep in mind that many other variables should be taken into consideration along with maternal age in the assessment of the number of oocytes needed to obtain at least one euploid blastocyst in IVF treatments.

Wider implications of the findings: Results from this study may constitute a useful tool for both clinical and patient. The clinician may be able to better decide the best strategy for each patient, while the patient will understand more easily this information, helping her morally with the treatment.

O-185 A clinically robust machine learning model for selecting the first FSH dose during controlled ovarian hyperstimulation: incorporating clinical knowledge to the learning process

N. Correa Mañas[1], J. Cerquides[2], J.L. Arcos[2], R. Vassena[1], M. Popovic[1]

[1]EUGIN group, Research and Development, Barcelona, Spain
[2]IIIA-CSIC, Learning Systems, Bellaterra, Spain

Study question: Can we improve the selection of the first dose of follicle stimulating hormone (FSH) for IVF patients by incorporating clinical evidence with machine learning?

Summary answer: A significant improvement in correct dose prescription is achieved when using a FSH dosing model that integrates a novel machine learning methodology with clinical knowledge.

What is known already: The appropriate selection of the initial FSH dose during controlled ovarian hyperstimulation (COH) is key for ART success. An optimal number of oocytes should be obtained for achieving pregnancy, while also avoiding complications for the patient. While clinical protocols achieve good results for the majority of patients, further refinements in individualized FSH dosing may improve safety while reducing the risk of poor response. Machine learning techniques have been applied to dose/response problems with promising results. However, the observational datasets used to train the models are often incomplete and biased, leading to less clinically robust predictions.

Study design, size, duration: We used a database of 2713 first cycles performed between January 2011 and December 2019, across five clinics to train the model. Predictors included age, body mass index (BMI), anti-Müllerian hormone (AMH) levels and antral follicle count (AFC). First FSH dose and number of mature oocytes retrieved were also recorded. Another 273 cycles performed between January 2020 and September 2021 were used for validation. Dosing was performed by 41 clinicians (mean 12 years of experience).

Participants/materials, setting, methods: The model was developed in Python and trained while incorporating available clinical evidence. The relationship between FSH dose and response (number of mature oocytes) was specified by assuming a positive linear function. Rules were incorporated to penalize dose changes that resulted in poorer outcomes compared to the clinician, and to discourage large dose modifications by the model. These same rules were applied during the validation phase. Comparisons were assessed by Chi-squared test with Bonferroni correction.

Main results and the role of chance: Mean maternal age was 37.1 ± 4.9 years. Patients had a mean BMI of 23.8 ± 4.2, AFC of 11.9 ± 7.7 and AMH of 2.4 ± 2.3. They were prescribed a first dose of 247.0 ± 59.0 IU of FSH and obtained 7.3 ± 5.3 mature oocytes after pick-up. An optimal outcome was defined as 10-15 mature oocytes retrieved, and 300 IU was the maximum FSH dose allowed. In the validation dataset, we observed that 22.9% patients could have received a higher FSH dose (<10 mature oocytes collected), 69.3% were correctly prescribed (10-15 mature oocytes or no change in dose was required), while 7.9% needed a decrease in FSH dose (>15 mature oocytes). In the machine learning model 9.4% of patients required a dose increase, 80.5% were correctly prescribed and 7.9% needed a decrease in dose. Accordingly, the model rescued 11.6% of patients that would have otherwise achieved suboptimal outcomes. Ultimately, when compared to the clinicians, the model significantly reduced the number of patients that required a dose increase, and significantly improved the number of patients that were prescribed a correct dose ($p < 0.05$).

Limitations, reasons for caution: The model assigned a non-conservative dose increase to 2.3% of patients, potentially leading to a risk of ovarian hyperstimulation syndrome. Moreover, hyper-responders were underrepresented in the database, resulting in no significant improvements in the dose/outcome relationship for this subgroup.

Wider implications of the findings: Coding clinical knowledge into the training of clinically relevant machine learning models ensured adherence to scientific evidence, and improved model performance while making conservative changes. This approach is critical for the safe and robust clinical implementation of interventional models.

O-186 The implementation of a novel algorithm for monitoring ovulation in an IVF mixed protocol may simplify stimulation monitoring

J. Ben-Guigui[1], R. Hemmings[2], F. Bissonnette[3], I.J. Kadoch[2]

[1]OVO Fertility Clinic, Fertility, Montréal, Canada
[2]OVO Fertility Clinic, Fertility, Montreal, Canada
[3]OVO Fertility Clinic, Fertilty, Montreal, Canada

Study question: Which patients are eligible to skip ovulation monitoring before day 10 in In Vitro Fertilization (IVF) and what are the financial implications?

Summary answer: Thanks to our innovative gonadotropin prescription algorithm, patients with low ovarian reserve and maximum ovarian stimulation may not require monitoring until day 10 of IVF.

What is known already: In most fertility clinics, the standard procedure for IVF is early monitoring on day 6 of ovarian stimulation. Our focus is on personalizing the stimulation protocol by identifying the optimal dose of gonadotropin. With the aid of our unique algorithm, we aim to streamline monitoring. Frequent ultrasound examinations required for IVF can impose restrictions and create a burden for patients, resulting in increased costs for both patients and physicians.

Study design, size, duration: In a retrospective study conducted from April 2021 to August 2022 at the OVO clinic in Montreal (Canada), participants included all patients over 18 years old who underwent an IVF stimulation cycle utilizing an antagonist protocol and a customized mixed protocol prescription consisting of follitrophin delta and human menopausal gonadotropin, based on the patient's weight and anti-Mullerian hormone level. The sudy was approved by Veritas IRB, an independent ethic committee. Tracking number of study :2023-3189-13659-2

Participants/materials, setting, methods: In the study, gonadotropin dosages were assigned either based on our algorithm (group 1) or at the physician's discretion (group 2). Ultrasound and hormonal analysis were performed on day 6. Following the physician's evaluation, adjustments to the gonadotropin dosage were made if necessary. The common trigger criteria was the presence of at least three follicles measuring between 16 and 22mm.

Main results and the role of chance: The study included 714 patients meeting the inclusion criteria. In group 1, there was a high percentage of patients stimulated with the maximum doses (80.3% compared to 22.5% in group 2). No dosage modifications or incidents of ovarian hyperstimulation syndrome were observed in group 1. Only 4.5% of patients ($n = 16$) triggered ovulation before day 10 (on day 9). In the non-maximal dose population, patients treated according to the algorithm (group A) experienced significantly fewer changes to the gonadotropin dosage at day 6 compared to patients treated based on the physician's discretion only (group B) (24.6% vs 46.9%, $p < 0.001$). The dosage of gonadotropins was notably more frequent adjusted in group B (46.9% vs 24.6%, $p < 0.001$). A higher risk of ovarian hyperstimulation syndrome was significantly more frequent in the non-maximal dose population compared to the maximal dose population (64.6% vs 27.5%, $p < 0.01$). These findings suggest that ovulation monitoring may not be necessary in the population stimulated to the maximum dose. This could result in 478 ultrasound and blood tests being avoided in the context of this study.

Limitations, reasons for caution: The data was obtained through a retrospective analysis. However, not monitoring before day 10 could pose a risk of delaying the cancellation of the IVF cycle, resulting in unnecessary treatment continuation.

Wider implications of the findings: This significant study indicates that, thanks to our algorithm, monitoring only on day 10 would be adequate for patients with low ovarian reserve who are stimulated to the maximum dose. Further validation of this strategy can be conducted through a randomized prospective study or with the use of different gonadotropins.

Trial registration number: non applicable

O-187 The combination of machine learning and pharmacogenetics for the prediction of sub-optimal ovarian response

J.A. Ortiz[1], B. Lledó[1], S. Myles[1], R. Morales[1], J. Guerrero[2], A. Bernabeu[3], R. Bernabeu[3]

[1]Instituto Bernabeu, Molecular Biology and Genetics, Alicante, Spain
[2]Instituto Bernabeu, Embryology, Alicante, Spain
[3]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: Can an artificial intelligence (AI)-based model predict the risk of suboptimal ovarian response using patient genetic data?

Summary answer: AI-based predictive models can identify relevant predicting factors for suboptimal ovarian response, including several genetic variants.

What is known already: A substantial proportion of women classified as "normo-responders" may not reach the optimal range of oocytes retrieved after COS. Polyzos and Sunkara (2015) defined a new category of women (15-36%) with a worse prognosis and a "suboptimal" level of ovarian response in which the number of oocytes retrieved ranges between 4 and 9 oocytes.

The explanation for this behavior has been suggested to be genetic and indeed variants in FSH receptor and LH subunit-B have been identified that predispose to lower ovarian sensitivity to stimulation. Therefore, these women might require higher doses of gonadotropins or longer stimulations.

Study design, size, duration: This observational study included a retrospective analysis of 1370 ovarian stimulations from egg donors performed between March 2018 and April 2022. The oocyte donor candidates were selected according to our clinic donation program requirements and ASRM and ESHRE guidelines for oocyte donation. They were stimulated following a progesterone-primed ovarian stimulation protocol. All donors started stimulation with 150-300 IU/day of FSH according to AFC and BMI. A GnRH agonist was used for final oocyte maturation.

Participants/materials, setting, methods: Oocyte donors were healthy women between 18 and 35 years old (n = 504). In order to establish the predictive machine learning models, patient characteristics and controlled ovarian stimulation data were recorded in a data frame. In addition, donors were genotyped for 31 variants corresponding to 16 genes associated with ovarian response.

The association between the different variables and risk of suboptimal ovarian response was analysed using SPSS (v23.0) and R (v. 4.2.0) statistical software.

Main results and the role of chance: The oocyte donors had a mean age of 25.4 ± 4.0 and a high ovarian reserve (AFC: 18.4 ± 7). The mean number of oocytes retrieved after ovarian stimulation was 16.3 ± 7.5, of which 13.1 ± 6.4 were mature. Despite being young women with good ovarian reserve, 16.4% of the stimulations were suboptimal (4-9 oocytes retrieved).

Classical statistical method (binary logistic regression) and 5 different supervised classification machine learning algorithms (multi-layer perceptron, support vector-machines, k-nearst neighbors, random forest and eXtreme Gradient Boosting (XGBoost)) were used to establish a prediction model for suboptimal ovarian response.

The model with the highest AUC value was the XGBoost (0.876). The accuracy, sensitivity and specificity were 0.798, 0.809 and 0.787 respectively. The variables that had the greatest predictive power in the best machine learning algorithm (XGBoost) were: age, BMI, AFC and total gonadotrophin dose. In addition, four genetic variants were identified that modified the risk of a suboptimal ovarian response:

-*ESR2* (oestrogen receptor; c.*39G>A).

-*LHB* (LH beta subunit; c.82T>C/p.Trp28Arg).

-SOD2 (superoxide dismutase; c.47T>C/p.Val16Ala). A mitochondrial enzyme that catalyses the detoxification and protection against redox damage that can occur in COS.

-and TP53 (tumour suppressor protein; c.215C>T/p.Pro72Leu) that exerts a protective effect on DNA damage in folliculogenesis.

Limitations, reasons for caution: Our investigation was performed with retrospectively collected data, and hence it will be of importance to collect data prospectively to confirm that the new identified variants are associated with suboptimal ovarian response also in the IVF population.

Wider implications of the findings: The combination of AI and pharmacogenetics has led to the identification of genetic variants that might predispose to suboptimal ovarian response. Women who carry these variants (erroneously considered as normo-responders) could be candidates for personalization of their ovarian stimulation treatment with higher doses of gonadotrophins and/or longer stimulations.

[3]Technical University of Denmark, Department of Biotechnology and Biomedicine, Kgs. Lyngby, Denmark
[4]Hospital Universitario La Fe, Gynecology, Valencia, Spain

Study question: Can single-cell transcriptomics and proteomics contribute to a better understanding uterine of leiomyoma tumorigenesis?

Summary answer: We demonstrate the significant involvement of the MAPK, PI3K-Akt, and proteoglycan pathways in smooth muscle, endothelial and perivascular cells in leiomyoma tumorigenesis.

What is known already: Uterine leiomyomas (LM), also known as fibroids, are benign tumors of the uterus that arise from the myometrium. Previous studies have shown cellular heterogeneity in both myometrium and uterine leiomyomas, although cell spatial location within the tissue has not been shown. Further, no data describing single-cell-level proteomic differences and key pathways involved in uterine LM tumorigenesis have yet been reported.

Study design, size, duration: A prospective, observational, and biomedical study of cohorts was conducted at Hospital La Fe (Valencia, Spain) for one year. Single-cell RNAseq (scRNA-seq; n = 16) and single-cell proteomic (scP; n = 16) analyses were performed on eight sample pairs of LM and matched myometrium (MM), to generate a high-resolution transcriptomic and proteomic map decoupled from cell type, state, and spatial location.

Participants/materials, setting, methods: After obtaining informed consent, LM and MM samples were collected from eight patients between 35-50 years undergoing hysterectomies. Part of the samples were preserved in paraffin for spatial transcriptomics using VISIUM (10x Genomics). While the remaining tissues were dissociated into single-cell suspensions and subjected to Chromium Controller and Orbitrap Eclipse Tribid mass spectrometry for scRNA-seq and scP, respectively. All data were analyzed using publicly available R/Python tools.

Main results and the role of chance: After restrictive quality control filtering, we analyzed a total of 52,599 and 5,909 cells by scRNA-seq and scP, respectively. While LM and MM possessed similarities in terms of cellular composition, they displayed differential expression of genes and proteins across all the cell populations studied, particularly in smooth muscle, endothelial and perivascular cells. In LM samples, these cell populations displayed impaired MAPK signaling, which acts as a signal integrator for growth factors, estrogen, and vitamin D. We also observed alterations in the PI3K-Akt and

proteoglycan pathways in LM smooth muscle and perivascular clusters, which relate to cell proliferation and tumor growth. Additionally, we encountered a subset of consistently dysregulated genes in all LM populations, which may suggest the existence of a shared tumorigenic pathway independent of cell type. Spatial transcriptomics further demonstrated relationships between cells and their relative locations within the tissue, which we validated by immunofluorescence. Together, our results highlight the relevance of specific cell populations in LM tumorigenesis.

Limitations, reasons for caution: This study involved a sample cohort limited to Caucasian women; therefore, further studies including more patients, and addressing racial disparities will help to generalize these findings to a broader population.

Wider implications of the findings: Our work describes an unprecedented transcriptomic and proteomic analysis of LM and MM at single-cell resolution, which supports a novel understanding of myometrial tumorigenesis.

O-189 Extracellular vesicles derived from human myometrial cells support endometrial mesenchymal stromal/stem cells

R. Chan[1], S. Zhang[1], E. Ng[1], W. Yeung[2]

[1]*The University of Hong Kong, Obstetrics & Gynaecology, Hong Kong, Hong Kong*
[2]*The University of Hong Kong Shenzhen Hospital, Shenzhen Key Laboratory of Fertility Regulation, Shenzhen, China*

Study question: Whether other forms of intercellular communication such as extracellular vesicles (EVs) participate in stem cell maintenance in the human endometrium.

Summary answer: The present study revealed the involvement of EVs as a novel intercellular communication method between endometrial mesenchymal stem cells (eMSC) and their surrounding niche.

What is known already: In human endometrium, many studies have demonstrated the importance of EVs in mediating various physiological as well as pathological processes. Our group has demonstrated that the myometrial cells are candidate niche cells of eMSC modulating their biological function. We also demonstrate the Notch signaling pathway is involved in endometrial stem cell regulation. Although classical Notch signaling relies on direct cell contact dependent interactions, this pathway can also be activated at a distance by EVs containing Notch ligands. Therefore, we hypothesized that certain Notch ligand(s) are packaged into the myometrial EVs to mediate stem cell functions.

Study design, size, duration: Sequential beading with magnetic beads coated with anti-CD140b and anti-CD146 antibodies was used to isolate eMSC ($CD140b^+CD146^+$ cells) from endometrial tissues from proliferative (n = 15) and secretory (n = 10) phase. Myometrial derived EVs (n = 17) were isolated by ultracentrifugation. The EVs were characterized by transmission electron microscopy and western blotting.

Participants/materials, setting, methods: Endometrial samples obtained from women aged 41 – 52 years undergoing total abdominal hysterectomy. EMSC were cocultured with myometrial EVs and the percentage of eMSC was analysed by flow cytometry. Blockage the secretion of EVs was performed by transfection of Rab27a siRNA. Western blot analysis and gene silencing approach validated the role of Notch signaling in eMSC. The therapeutic features of transplanted eMSC/myometrial EVs was determined using the mouse injured endometrial model.

Main results and the role of chance: EVs released from myometrial cells can be internalized by eMSC, leading to a significant effect on stemness of eMSC. Pharmacological inhibition of Notch signaling with DAPT or silencing of Notch 1 nullified these stimulatory effects. Myometrial EVs contains a high amount of the notch ligand – JAG1, thus inducing a strong Notch activity in eMSC. When JAG1 was silenced in the myometrial EVs, the self-renewal and clonogenic activity was reduced. Combined transplantation of eMSC with myometrial EVs improves the therapeutic effect of eMSC in endometrial regeneration in vivo. The observed therapeutic feature was potentially achieved by elevating the cell proliferation and suppressing apoptosis in the injured mouse endometrium.

Limitations, reasons for caution: Whether other signaling pathway are involved in the stimulatory effect of myometrial EVs in eMSC activities remains unknown. Also, EVs derived from other endometrial cell types i.e. epithelial cells may also regulate eMSC function.

Wider implications of the findings: Our findings revealed that myometrial EVs stimulated the biological function of eMSC via the Notch signaling. In the near future, it would be important to explore whether Notch signaling pathway plays a role in the injured mouse endometrium transplanted with eMSC/myometrial EVs.

O-190 Establishment of non-invasive prediction models for diagnosis of the subtypes and tissue composition of uterine leiomyomas by machine learning using MRI data

T. Tamehisa[1], S. Sato[1], T. Sakai[1], R. Maekawa[1], M. Tanabe[2], K. Ito[2], N. Sugino[1]

[1]*Yamaguchi University Graduate School of Medicine, Obstetrics and Gynecology, Ube, Japan*
[2]*Yamaguchi University Graduate School of Medicine, Radiology, Ube, Japan*

Study question: We investigated whether machine learning models using MRI data can predict the subtypes and tissue composition of uterine leiomyomas.

Summary answer: Our machine learning models using MRI data were able to predict the subtypes and tissue composition of uterine leiomyomas with high accuracy.

What is known already: Recently, somatic mutations in the Mediator complex subunit 12 (MED12) gene were found to be a biomarker of uterine leiomyomas, which is detected in about 70% of uterine leiomyomas. Uterine leiomyomas are classified into two subtypes with or without the MED12 mutation. These subtypes differ in the ratio of smooth muscle cells and fibroblasts and in the amount of collagen fibers. In addition, sensitivities to female hormones differ between smooth muscle cells and fibroblasts. Thus, the effect of therapeutic drugs (GnRH analogs and selective progesterone receptor modulators) may differ depending on the subtypes and tissue composition of uterine leiomyomas.

Study design, size, duration: We analyzed 90 uterine leiomyoma nodules (MED12 mutation-positive and negative = 62 and 28) obtained from 51 women who underwent surgery at our hospital between 2020 and 2022. Seventy-one uterine leiomyomas (MED12 mutation-positive and negative = 49 and 22) were assigned to the primary dataset to establish the prediction models. Nineteen uterine leiomyomas (MED12 mutation-positive and negative = 13 and 6) were assigned to the test dataset to validate the prediction model utility.

Participants/materials, setting, methods: For each leiomyoma, the tumor signal intensity was quantified by five MRI sequences (T2WI, ADC, T1map, T2*BOLD, MTC) for evaluating the collagen amount. After surgery, genotyping of MED12 was examined and Trichrome staining was performed to quantify the collagen amount. Using these results, we established the prediction models based on machine learning by applying support vector classification and logistic regression for subtype prediction, and support vector regression and Ridge regression for tissue composition prediction.

Main results and the role of chance: The signal intensity of all five MRI sequences differed significantly between the subtypes. The cross-validation within the primary dataset showed that support vector classification and logistic regression models using five MRI sequences and MED12 genotyping data were highly predictive of the subtypes (AUC: 0.984 and 0.995, respectively). The validation using the test dataset showed that both models were able to predict the subtypes for all uterine leiomyomas (AUC: 1.000, both). This result showed higher accuracy than each MRI sequence's cut-off value alone. On the other hand, four MRI sequence values (other than ADC) showed a significant correlation with the collagen amount. However, to improve

accuracy, we added the ADC data and the result of the subtype predicted by the preceding models to the predictors for the collagen amount. Support vector regression and Ridge regression models using five MRI sequences and Trichrome staining data were shown to be highly predictive of the collagen amount in cross-validation within the primary dataset (R2: 0.570 and 0.525, respectively) and in validation using the test dataset (R2: 0.648 and 0.675, respectively). Moreover, the prediction models using only T2WI and ADC, which are taken in general clinical practice, were as accurate as using five MRI sequences.

Limitations, reasons for caution: In this study, we used limited data by using one specific MRI machine in a single center to establish the prediction models. We have not verified that similar results would be obtained under different conditions. Therefore, further training and evaluation in larger cohorts are required for clinical use.

Wider implications of the findings: The prediction models established in this study may be useful in clinical support such as predicting the effect of drug therapy and selecting therapeutic drugs, such as GnRH analogs and selective progesterone receptor modulators. Their utilities will be confirmed by validation using our prediction models in studies involving drug therapy.

O-191 Effects of relugolix combination therapy (Relugolix-CT) on uterine fibroid (UF) and uterine volume through 52 weeks: post hoc analysis of the LIBERTY Long-Term Extension study

R. Venturella[1], A. Lukes[2], R. McLean[3], D. Zhai[4], A. Al-Hendy[5]

[1]*University Magna Graecia, Chair of Obstetrics and Gynecology, Catanzaro, Italy*
[2]*Carolina Women's Research and Wellness Center, Women's Wellness Clinic, Durham, U.S.A.*
[3]*Myovant Sciences Inc, Clinical Development, Brisbane, U.S.A.*
[4]*Myovant Sciences Inc, Biostatistics, Brisbane, U.S.A.*
[5]*University of Chicago, Department of Obstetrics and Gynecology, Chicago, U.S.A.*

Study question: How does baseline UF and uterine volume impact the proportion of women achieving meaningful UF and uterine volume reductions with Relugolix-CT through 52 weeks?

Summary answer: Women with larger UF and uterine volumes at baseline may be more likely to experience clinically meaningful reductions of UF and uterine volume with Relugolix-CT.

What is known already: In the randomised, Phase 3 LIBERTY 1 and 2 pivotal studies, the efficacy and safety of once-daily Relugolix-CT (relugolix 40 mg, estradiol 1 mg, norethisterone acetate 0.5 mg) were demonstrated in premenopausal women (aged 18–50 years), with a significant reduction in UF-associated heavy menstrual bleeding (HMB) vs placebo, and preserved bone mineral density (BMD) through 24 weeks. The open-label, 28-week LIBERTY Long-Term Extension (LTE) study continued to demonstrate sustained menstrual blood loss reductions and preservation of BMD, alongside reductions in UF and uterine volume.

Study design, size, duration: The LIBERTY 1 and 2 studies of Relugolix-CT were conducted in 770 premenopausal women with UF-associated HMB. Women were randomised 1:1:1 to receive Relugolix-CT or placebo for 24 weeks, or delayed Relugolix-CT (relugolix 40 mg alone for 12 weeks, then Relugolix-CT for 12 weeks). Women who completed the pivotal trials were eligible to participate in the LIBERTY LTE study, receiving open-label Relugolix-CT for an additional 28 weeks.

Participants/materials, setting, methods: Endpoints of the LTE included change from baseline to Week 52 in UF and uterine volume. This *post hoc* analysis assessed the proportion of women who experienced a clinically meaningful reduction in UF or uterine volume of $>25\%$ or $>50\%$ through 52 weeks of Relugolix-CT. Subgroup analyses were performed to descriptively summarise the impact of UF and uterine volume at baseline ($<25cm^3$ or $\geq 25cm^3$; $<300cm^3$ or $\geq 300cm^3$, respectively) on change in UF and uterine volume.

Main results and the role of chance: In total, 477 women enrolled in the LTE, 363 completed 52 weeks of treatment, and 163 received Relugolix-CT continuously up to 52 weeks. At baseline, the mean (standard deviation) volume of the largest UF was 80.0 (145.1) cm^3; mean (SD) uterine volume was 386.7 (320.5) cm^3 in the Relugolix-CT group.

At Week 24, 52.6% and 30.3% of women in the Relugolix-CT group experienced $>25\%$ and $>50\%$ reduction in UF volume, respectively. These proportions increased to 61.1% and 36.6%, respectively, at Week 52. For uterine volume, 36.1% and 4.5% experienced a $>25\%$ and $>50\%$ reduction at Week 24, increasing to 41.2% and 9.6% at Week 52.

At Week 52, of 81 women with a baseline UF volume of $<25cm^3$, 52.4% and 27.0% experienced a $>25\%$ and $>50\%$ reduction in UF volume, respectively; 69.1% and 45.6% of 81 women with a baseline UF volume of $\geq 25cm^3$ experienced $>25\%$ and $>50\%$ reductions in UF volume, respectively.

At Week 52, of 96 women with a baseline uterine volume of $<300cm^3$, 38.5% and 6.4% experienced a $>25\%$ and $>50\%$ reduction in uterine volume; 44.8% and 13.8% of 67 women with a baseline uterine volume of $\geq 300cm^3$ experienced $>25\%$ and $>50\%$ reductions in uterine volume.

Limitations, reasons for caution: The study was conducted as an open-label study without a control group over the 28 weeks of the extension period. The present data are from a *post hoc* analysis of LIBERTY data without predefined criteria.

Wider implications of the findings: Treatment with Relugolix-CT led to a substantial reduction of UF and uterine volume in a large proportion of women with UF-associated HMB. Women with larger UF and uterine volume at baseline may be more likely to experience substantial reductions of UF and uterine volume.

Study question: Does tubal flushing by hysterosalpingo-foam-sonography (HyFoSy) or hysterosalpingography (HSG) affect tubal patency in infertile women?

Summary answer: Tubal flushing by HyFoSy and HSG does not increase the number of women with visible bilateral tubal patency.

What is known already: HyFoSy and HSG are two frequently used methods to visualize tubal patency by flushing a contrast fluid through the Fallopian tubes, while the uterus and Fallopian tubes are imaged using respectively fluoroscopy and ultrasound. Tubal flushing by HSG, specifically with oil-based contrast, improves live birth rates in infertile women. The mechanism of this fertility-enhancing effect is still not completely understood. The potential fertility-enhancing effect of other tubal flushing methods, for example HyFoSy, are studied less frequently. Here, we investigated whether tubal flushing affect tubal patency, and therefore could explain the fertility-enhancing effect of tubal flushing.

Study design, size, duration: This is a secondary analysis of the FOAM-trial, a multi-center RCT in which women were assigned to undergo tubal flushing by HSG and HyFoSy in randomized order. They either had HyFoSy first and then HSG or the other way around. Here, we assess whether tubal flushing by either HSG or HyFoSy led to differences in tubal patency. We also investigate whether the type of contrast used during HSG (oil -and water based) influenced tubal patency.

Participants/materials, setting, methods: We studied infertile women with indication for tubal patency testing. Women with anovulatory cycles, endometriosis or with a partner with male infertility were excluded. The main outcome was the number of women with bilateral tubal patency. This outcome, was compared in two analyses: 1) Tubal flushing by HyFoSy versus no flushing, with HSG as reference test, and 2) Tubal flushing by HSG (with oil – or water contrast) versus no flushing, with HyFoSy as reference test.

Main results and the role of chance: Between May 2015 and January 2019, 1,160 women were included. There were 957 women who underwent HyFoSy with interpretable results and 1,081 women who underwent HSG with interpretable results.

Tubal flushing by HyFoSy versus no tubal flushing, with HSG done in all women as reference test, evaluating the effect of tubal flushing by HyFoSy, resulted in a comparable number of women with visible bilateral tubal patency: 467/537 (87%) vs. 472/544 (87%) ; (RR 1.00; 95%CI: 0.96-1.05).

Tubal flushing by HSG (with both water –and oil-based contrast) versus no tubal flushing, with HyFoSy done in all women as reference test, evaluating the effect of tubal flushing by HSG, did not show an increase of women with visible bilateral tubal patency: 394/471 (84%) vs. 428/486 (88%); RR 0.95; (95%CI:0.90-1.00).

Tubal flushing by HSG with oil-based contrast versus no flushing, with HyFoSy as reference test, resulted in a comparable number of women with visible bilateral tubal patency: 283/330 (86%) vs. 271/308 (88%); RR 0.97; (95%CI:0.92-1.04). Tubal flushing by HSG with water-based contrast versus no flushing, with HyFoSy as reference test, did show a decrease of women with visible bilateral tubal patency: 108/137 (79%) vs. 156/171 (91%); RR 0.90 (95%CI:0.83-0.98).

Limitations, reasons for caution: It needs to be noted that subtle improvements of tubal patency, caused by initial tubal flushing with either HyFoSy or HSG, cannot be detected on respectively ultrasound and fluoroscopy images and were therefore not assessed in this study.

Wider implications of the findings: The therapeutic effect of tubal flushing cannot be explained by dissolving visible obstruction in the Fallopian tubes. This suggests that the therapeutic effect of tubal flushing mainly applies to women with anatomically normal Fallopian tubes.

O-193 Opening the black box: why do euploid blastocysts fail to implant? A systematic review and meta-analysis

D. Cimadomo[1], L. Rienzi[12], A. Conforti[3], E. Forman[4], S. Canosa[5], F. Innocenti[1], M. Poli[67], J. Hynes[4], L. Gemmell[4], A. Vaiarelli[1], C. Alviggi[3], F.M. Ubaldi[1], A. Capalbo[7]

[5]*Livet, GeneraLife IVF, Turin, Italy*
[6]*Dijklander Hospital, Centrum voor Kinderwens, Purmerend, The Netherlands*
[7]*Juno Genetics, Juno Genetics Italy, Rome, Italy*

Study question: What are the embryonic, maternal, paternal, clinical and laboratory features associated with the live-birth-rate (LBR) after euploid blastocyst transfer?

Summary answer: Delayed blastulation, poor blastocyst quality, maternal age ≥38 years, obesity, previous repeated-implantation-failure (RIF), poor or multiple manipulations may reduce the LBR per euploid blastocyst transfer.

What is known already: Euploidy assessed at the blastocyst stage through comprehensive-chromosome-testing (CCT) technologies during IVF cycles with preimplantation genetic testing for aneuploidies (PGT-A) represents the strongest predictor of embryo implantation potential. Nevertheless, its positive predictive value hardly exceeds 50-60%. The current gap of knowledge on the causes of euploid blastocysts' reproductive failure is known as "the black box of implantation".

Study design, size, duration: Systematic search conducted up to August-2021 with the keywords "(blastocyst OR day 5 embryo OR day 6 embryo OR day 7 embryo) AND (euploid OR chromosomally normal OR preimplantation genetic testing) AND (implantation OR implantation failure OR miscarriage OR abortion OR live birth OR biochemical pregnancy OR recurrent implantation failure)". Among 1608 items, prospective/retrospective studies and randomized controlled trials (RCTs) investigating associations with LBR and/or miscarriage rates (MR) after non-mosaic euploid blastocyst transfers were scrutinized.

Participants/materials, setting, methods: 335 retrospective, 30 prospective papers and 7 RCTs were included. PRISMA guideline, PICO model, and ROBINS-I and ROB 2.0 scoring for bias, were adopted. Funnel plots and trim and fill methods were used to visually inspect bias regarding the LBR. Categorical data were combined with a pooled-OR. The random-effect model was used for meta-analyses. Between-study heterogeneity was addressed using I^2. Whenever not suitable for the meta-analysis, the included studies were simply described for their results.

Main results and the role of chance: Inner-cell-mass C-grade (7 studies, OR:0.37, 95%CI:0.27-0.52, $p < 0.01$), trophectoderm C-grade (9 studies, OR:0.53, 95%CI:0.43-0.67, $p < 0.01$), overall blastocyst quality <BB (8 studies, OR:0.4, 95%CI:0.24-0.67, $p < 0.01$) developmental delay (18 studies, OR:0.56, 95%CI 0.49-0.63, $p < 0.01$) and, by qualitative analysis, some morphodynamic abnormalities pinpointed through time-lapse microscopy (abnormal cleavages, spontaneous collapse, longer tM, tB, and blastulation) were all associated with poorer reproductive outcomes. Slightly lower LBR was reported for women ≥38 years (7 studies, OR:0.87, 95%CI:0.85-1.00, $p = 0.05$), while maternal BMI>30 involved both lower LBR (2 studies, OR:0.66, 95%CI:0.55-0.79, $p < 0.01$) and higher MR (2 studies, OR:1.8, 95%CI:1.08-2.99, $p = 0.02$). The experience of previous RIF was also associated with lower LBR (3 studies, OR:0.72, 95%CI:0.55-0.93, $p = 0.01$). By qualitative analysis, abnormal progesterone level prior to transfer impaired LBR and MR. Among clinical policies, vitrified-warmed transfer was more effective than fresh (2 studies, OR:1.56, 95%CI:1.05-2.33, $p = 0.03$). Lastly, multiple vitrification-warming cycles (2 studies, OR:0.41, 95%CI 0.22-0.77, $p < 0.01$) and, by qualitative analysis, high biopsy cellularity may slightly impact the LBR, while simultaneous zona opening and biopsy protocol showed higher LBR than the day3 hatching-based protocol (3 studies, OR:1.41, 95%CI:1.18-1.69).

Limitations, reasons for caution: The associations outlined mostly issue from retrospective and/or few studies or studies with a limited sample size, therefore the level of evidence is low or very low. Moreover, some findings represent "prognosis without promise" because the poorer outcome of euploid blastocysts is not clinically actionable (e.g., women ≥38 years).

Wider implications of the findings: Future research should target: (i) the mechanisms involved in reproductive aging beyond *de novo* chromosomal abnormalities, and how environment and nutrition may accelerate or exacerbate their consequences; (ii) uterine evaluation and blastocyst-endometrial dialogue; (iii) standardization of embryo assessment and IVF protocols; (iv) additional (non-)invasive tools for embryo selection.

[5]University of Toronto, Department of Physiology, Toronto, Canada
[6]University of Toronto, Institute of Medical Sciences, Toronto, Canada
[7]University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada

Study question: Is there an association of the timing of blastulation (TE biopsy day) on embryo ploidy and pregnancy outcome after frozen embryo transfer?

Summary answer: Blastocysts expanded on day 5 are more likely to be euploid and result in an ongoing pregnancy after single euploid frozen embryo transfer (FET).

What is known already: Embryo selection for ET is commonly based on static morphological parameters for patients undergoing in vitro fertilization (IVF). Embryo quality on the day of biopsy in combination with preimplantation genetic testing (PGT) are considered important predictors for successful implantation. At present, coherent data regarding any association between the timing of blastulation with embryo ploidy and pregnancy outcomes following single FET are lacking. The aim of our study was to investigate the correlation of the culturing method and blastulation day (day 5/6/7) with embryo ploidy and outcomes of matched d5 vs d6 vs d7 FET cycles.

Study design, size, duration: This retrospective cohort study was performed at the CReATe Fertility Centre and its Reproductive Genetics Laboratory, between January 2019-December 2022. 29660 blastocysts from 5302 cycles (3645 patients) were analyzed using high resolution NGS PGT-A (10Mb resolution for copy number variations and 30%-70% for mosaicism). Pregnancy outcome data from 3942 single-FETs were analyzed. Average age of ovum provider was 32.9 ± 5.8 and sperm provider 39.1 ± 6.4. Clinical, laboratory and demographic data were obtained for statistical analysis.

Participants/materials, setting, methods: Embryos were allocated into four groups based on static morphological grading before biopsy on either d5 (n = 8312), d6 (n = 19183) or d7 (n = 2165): Good (>1/2BB), n = 5648, Average (1BB, 2BB), n = 10492, Poor (<1/2 BB) n = 12219 and Early blast, n = 1301. Embryo ploidy in each group and pregnancy outcomes from single euploid FET were compared between matched cycles of day 5 biopsy to days 6 and 7.

Main results and the role of chance: PGT-A analysis of 29660 embryos showed 53.1% were euploid, 33.9% were aneuploid and 13.0% were mosaic. There were significantly higher proportion of euploid embryos among those biopsied on d5 compared to d6 and d7 with average morphology grade (p = 0 O.R.=1.35979; p = 0.008098 O.R.=1.34442), poor (p = 0 O.R.=1.76481; p = 0 O.R.=2.73903) and early grades (p = 0 O.R.=2.71891; p = 0 O.R.=2.74271), but not among embryos with good grade (p = 0.244399 O.R.=1.07276; p = 0.182084 O.R.=1.38189).

Ongoing pregnancy rates were significantly higher for d5 vs d6 biopsied embryos, for all morphology grade groups: good (p = 0.030036 O.R.=1.26598), average (p = 0 O.R.=1.80782), poor (p = 0.000303 O.R.=1.89235) and early blasts (p = 0.049501 O.R.=3.30556). D5 blasts had higher ongoing pregnancy rates compared to d7 among average and poor morphology grade as well as early blast (p = 0.000419 O.R.=8.93182, p = 0.000036 O.R.=7.29464, p = 0.010034, respectively), except among good grade embryos (p = 0.885598 O.R.=0.9028). Continuous culture of embryos in Embryoscope™ versus conventional incubator did not influence the ploidy (n = 24321; n = 4756, respectively) or the pregnancy outcome after FET (n = 3134; n = 752, respectively) while comparing between each day of biopsy.

Limitations, reasons for caution: Although this is the largest sample size study to investigate the association of blastulation with ploidy and pregnancy outcomes, the sample size for d7 embryos is relatively low and results should be confirmed in a bigger study.

Wider implications of the findings: Prioritization of euploid embryos for transfer should consider the timing to blastulation and embryos biopsied on d5 should be considered before those biopsied on d6 or d7. This data has potential to shed light on the impact of normal chromosomal content on pre-implantation embryo development.

[3]University of Copenhagen, Department of Cellular and Molecular Medicine-Faculty of Health and Medical Sciences, Copenhagen, Denmark
[4]Bioinnovation Instute, Not applicable, Copenhagen, Denmark
[5]Copenhagen University Hospital Hvidovre, Fetal medicine unit- Department of Gynecology and Obstetrics, Hvidovre, Denmark

Study question: Is cffDNA in maternal blood applicable for fetal ploidy evaluation in early pregnancy loss, and what are the strengths and limitations of the method.

Summary answer: With a sensitivity of ~85% for aneuploidies and ~93% specificity, cffDNA-based testing is a robust method for evaluation of fetal ploidy status in PL.

What is known already: Pregnancy loss (PL) is an under investigated condition without precise prognostic models or evident treatments. From previous studies using karyotype and chromosomal microarray analysis it is described that approximately half of PLs are caused by fetal aneuploidy, but international guidelines still refrain from recommending routine genetic evaluation of PL. Traditional fetal cytogenetics are expensive and dependent on collection of pregnancy tissue containing fetal or chorionic tissue to avoid inconclusive results and maternal contamination. Consequently, chromosomal investigation of the lost fetus is lacking in most literature about PL and couples are currently not getting an explanation of their loss.

Study design, size, duration: As a part of the prospective Copenhagen Pregnancy Loss (COPL) cohort, 1000 consecutive women with PL (spontaneous miscarriage, missed miscarriage or anembryonic sac) before GA 22 weeks were recruited between Nov 12, 2020, and May 1, 2022. Results from the first 333 women were used to validate cffDNA-based testing compared with direct sequencing of the collected pregnancy tissue. Additional 667 women were included to evaluate cffDNA performance and result distribution in 1000 PLs

Participants/materials, setting, methods: Blood for cffDNA-based testing were drawn in STRECK © tubes before treatment was initiated or within 24 h after complete passage of pregnancy tissue. Pregnancy tissue was collected from the vacuum system if surgical treated or by home collection if medically treated and classified as fetal, chorionic villi or unknown tissue and sequenced at University of Copenhagen. Genome wide cffDNA-based testing and fetal fraction of DNA by SeqFF was performed at Hvidovre Hospitals NIPT Center.

Main results and the role of chance: Among invited candidates, the participation rate was 73%. Mean maternal age was 33.9 years (SD 5.2). Gestational age at inclusion ranged from 35 days to 149 days measured from last menstrual period with a mean of 70.5 days (SD 16.5), or 10 weeks+1 day. Mean maternal BMI was 24.6 kg/m^2 (SD 4.6) and 233 (23%) conceived after fertility treatment.

In 19 (6%) of the initial 333 women, collection of the pregnancy tissue failed for practical or psychological reasons. DNA was isolated from fetal tissue or chorionic villi in 228 (73%) cases, or from unknown tissue in 86 (27%) cases and thereby at a high risk of being maternal contaminated.

The sensitivity of cffDNA-based testing compared with the pregnancy tissue sequencing result was 85% (95% CI 79–90), specificity of 93% (88–96), accuracy of 89% (85–92), and Cohen's coefficient 0.78 showing substantial agreement.112 (11%) of 1000 total cffDNA analyses were inconclusive due to low fetal fraction (SeqFF<0.015 or < 0.025) or low sequencing quality. In instances of a conclusive result, 446 (50%) were euploid, 405 (46%) were aneuploid, and 37 (4%) contained multiple aneuploidies. The most common abnormal karyotypes identified were trisomy 16 (n = 91), monosomy X (n = 86), and trisomy 22 (n = 41).

Limitations, reasons for caution: The used platform for cffDNA-based testing does not report fetal polyploidy, uniparental disomy, and copy number variants found in approximately 10% of early PLs. Moreover, blood for cffDNA-based testing must be drawn with the pregnancy tissue in situ or within 24 hours limiting the window for testing.

Wider implications of the findings: Considering the difficulties of pregnancy tissue collection, it is relevant to introduce a pregnancy tissue-independent alternative. The validity of cffDNA-based testing for fetal ploidy status found in this study shows the potential of the method to improve clinical management and research in the field of PL.

Study question: What are the pregnancy and neonatal outcomes of prospective transfer of 565 mosaic embryos and what are the key determinants influencing the outcome?

Summary answer: Mosaic (diploid/aneuploid) embryos have a significant developmental potential with good neonatal outcomes allowing personalized management and evidence based prioritization of embryos for transfer.

What is known already: Since the first report of healthy babies born after mosaic transfer, the gradual accumulation of knowledge on mosaic embryo transfers in the International Registry of Mosaic Embryo Transfers provided the necessary reassurance for clinical management of mosaic embryos. Large and comprehensive data from single centres with consistent clinical genetic counselling and laboratory practices for preimplantation and prenatal testing offer valuable contribution to the current practices. The aim of this study was to evaluate the pregnancy and neonatal outcomes after mosaic embryo transfers and to evaluate for associations between embryo genetic aberrations, static morphology and specific outcomes.

Study design, size, duration: This is a retrospective cohort study that took place in a single academic IVF centre (The CReATe Fertility Centre, Toronto, Canada), where we analysed the results from high resolution PGT-A, embryo morphologic features and pregnancy outcomes of 3529 frozen embryo transfers from 2016-2022. Associated patient demographic data, transfer outcome and neonatal outcome of 2964 euploid and 565 mosaic embryo transfers were analyzed.

Participants/materials, setting, methods: All patients received genetic counselling prior to frozen embryo transfer. High resolution NGS PGT-A was performed using the Illumina platform and BluGnome and NxClinical for data analysis. Clinically relevant findings were aberrations >10Mb and mosaicism from 25%-75%. Comparison of clinical and morphological characteristics of euploid, low-level mosaic (25%-<50% aneuploid cells in trophectoderm biopsy), and high-level mosaics (50% -75%) was performed with R-statistical package, Mathlab and SSPS software. $p < 0.05$ with CI 95% was considered significant.

Main results and the role of chance: Of the total 565 mosaic embryos transferred 77.1% had mosaicism levels ≥25%-<50% (Group1-n=436): 54.8% had segmental chromosome mosaic (SCM)gain/loss, 45.2% had whole chromosome mosaicism(WCM)(trisomy/monosomy); and 22.9% had mosaic levels of ≥ 50-<70% (Group2-n=129)(50.4% with SCM and 49.6% with WCM). The overall ongoing pregnancy rate(OPR) for mosaic embryos was 33% and the miscarriage rate was 6%.

Compared with euploid embryos, mosaic embryos have significantly lower implantation (p = 0,OD0.62-CI[0.5-0.7]) and OPR(p = 0,OD0.5-CI[0.4-0.6]). Pregnancy outcomes are determined by level of mosaicism: Group1 have better implantation(p = 0.005,OD1.8-CI[1.18-2.78]) and OPR compared to Group2. High level of mosaicism independently affected the OPR of SCM(p = 0.003) and WCM(p = 0.02) embryos. WCM had lower implantation rates compared to SCM (p = 0.005,OD1.6-CI[1.15-2.27]). Mosaic monosomies had the lowest impanation and OPR of all mosaic embryos (14% and 8%,respectively). Within Group1 and Group2 good static morphology was associated with higher OPR for SCM and WCM embryos. Birth outcomes were available for 118 babies from mosaic-FET and from 802 euploid-FET. There is no difference in duration of pregnancy and birth weight between mosaic and euploid-FET. No gross-fetal anomalies were reported in the mosaic group at birth. There was one termination<20GW due to fetal anomalies and one stillbirth. For euploid transfers, 11 had fetal anomalies, there were 7-terminations and 2-stillbirths.

Limitations, reasons for caution: Although this is the largest single centre study to date that evaluated genomic, morphology and outcome data of mosaic transfers, the numbers are still low to analyze the impact of specific chromosomal aberrations on pregnancy outcome.

Wider implications of the findings: Mosaic embryos should be considered for transfer and prioritized based on the level of mosaicism, type of chromosomal aberration and static morphology. The implantation potential is lower than euploid embryos however established pregnancies result in healthy babies born at term and normal birth weight.

O-197 Vertical transmission of maternal mitochondrial DNA via extracellular vesicles (EVs) modulates embryo bioenergetics during the periconceptional period

F. Vilella[1], D. Bolumar[1], J. Moncayo-Arlandi[1], J. Gonzalez-Fernandez[1], A. Ochando[1], I. Moreno[1], C. Marin[2], A. Diez[3], C. Simon[4]

Study question: Does maternal endometrial mitochondrial (mt) DNA cargo of EVs modulate embryo bioenergetics during embryo implantation?

Summary answer: We demonstrate the vertical transmission of maternal mtDNA within endometrial-derived EVs and their uptake by the trophoblast which reduces mitochondrial respiration and ATP production.

What is known already: The release and uptake of membrane-enclosed compartments with specific cargos, commonly known as EVs, represents a novel cell-to-cell communication mechanism in physiological and pathogenic conditions. EVs are generally classified into three populations based on their biogenetic pathways, composition, and physical characteristics: apoptotic bodies (ABs), microvesicles (MVs), and exosomes (EXOs). Among other contents, EVs contain single- and double-stranded DNA, with their relative abundance varying depending on the cell and vesicle type. The vertical

transmission of EV-associated DNA has been proposed as a novel genetic material transfer mechanism that may impact genome evolution and tumorigenesis.

Study design, size, duration: Prospective observational multicenter analysis in which EVs were obtained from endometrial fluid from healthy donors aged 18–35 years (n = 10) during the receptive phase of their natural cycle and under hormonal replacement therapy in pre-receptive (P + 2), receptive (P + 5), post-receptive (P + 8) stages (n = 13).

Participants/materials, setting, methods: Endometrial EVs isolated using ultracentrifugation and classified according to `parameters obtained from electron microscopy, Western blotting, and size distribution analysis. DNA copy number identified using high throughput sequencing. EV-associated DNA tagged with 5-ethynyl-2'-deoxyuridine was followed by confocal imaging after co-incubation of EVs with murine embryos (n = 200). ATP levels assessed using the FLASC luciferase reporter system, and the Seahorse XFE96 extracellular flux analyzer used to measure embryo oxygen consumption rate (OCR) (n = 400).

Main results and the role of chance: The human endometrium secretes all three EV types - ABs, MVs, and EXOs - into the human endometrial fluid. Deep sequencing revealed that EVs encapsulated nuclear and mtDNA. When analyzing endometrial biopsies, we observed the reduced mtDNA content of endometrial cells and the activation of mitochondrial clearance mechanisms, which coincided with the time of embryo implantation together with specific enrichment in endometrial MVs secreted during the periconceptional period. EVs were internalized and DNA was transferred to the cytoplasm and nuclei of trophectoderm of murine embryos. We analyzed ATP concentrations in murine embryos and found a significant reduction in ATP levels following the coculture of embryos with a combination of all EVs types compared to control embryos cultured without endometrial EVs ($p < 0.001$). Finally, we demonstrated a reduction in the OCR in embryos treated with endometrial EVs obtained during the receptive phase compared with the pre-receptive phase. In conclusion, maternal EVs modulate the bioenergetics of the preimplantation embryo by increasing the embryo's metabolic rate and oxygen consumption during the periconceptional period.

Limitations, reasons for caution: These results were obtained using a combination of a human endometrial model and a murine embryo model.

Wider implications of the findings: Our results suggest that the vertical transmission of maternal mtDNA encapsulated within EVs to the trophectoderm might energetically assist the preimplantation embryo through the implantation process.

O-198 Obstetric and neonatal outcomes after natural frozen embryo transfer; results from a follow-up study of the Antarctica-2 RCT

T. Zaat[1], J.P. De Bruin[2], M. Goddijn[1], M. Van Wely[1], F. Mol[1]

[1]*Amsterdam UMC- Center for Reproductive Medicine, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Jeroen Bosch ziekenhuis, Obstetrics and gynaecology, Den Bosch, The Netherlands*

Study question: Do obstetric and neonatal outcomes of women who conceived through home-based monitoring of the ovulation in natural cycle frozen embryo transfer (NC-FET) differ compared to hospital-controlled monitoring of the ovulation in NC-FET using a hCG trigger?

Summary answer: We found no differences in obstetric and neonatal outcomes when home-based monitoring versus hospital-controlled monitoring of the ovulation in women undergoing NC-FET.

What is known already: NC-FET is associated with lower risk of adverse obstetric and neonatal outcomes compared with artificial cycle FET. The question of how to prepare the endometrium for FET, has now gained even more importance and taken on the dimension of safety into account as it should not simply be reduced to the basic question of effectiveness.

Study design, size, duration: Between April 10, 2018 and April 13, 2022, 1464 women were included in the Antarctica-2 RCT (n = 732 home-based monitoring and n = 732 hospital-controlled monitoring). For this study we performed a follow-up study in order to investigate obstetric and neonatal outcomes of the participating women with live births after the Antarctica-2 trial.

Participants/materials, setting, methods: We included only singleton livebirths. Main outcomes were gestational age, preterm birth (PTB), very preterm birth (very PTB), birth weight, large for gestational age (LGA) and small for gestational age (SGA). Additional outcomes included: gestational diabetes (GDM), hypertensive-disorders-of-pregnancy (HDP), pre-eclampsia (PE), abnormal placentation (including placenta previa and accrete), hospital admission during pregnancy, congenital anomalies and neonatal death. We calculated risk ratios and absolute risk differences (95% CI) using per protocol analysis.

Main results and the role of chance: Both studyarms resulted in similar live birth rates. Singleton live birth occured in 146 of 732 women (19.9%) following home-based and in 148 of 732 women (20.2%) following hospital-controlled monitoring. The mean gestational age in weeks was 39.0 (SD 0.3) for the home-based monitoring group versus 39.3 (SD 0.2) for the hospital-controlled monitoring group. We found no significant differences in preterm birth (5/146 versus 11/148, RR 1.00, 95% CI 0.90 – 1.10) or very preterm birth (1/146 versus 2/148, RR 1.00, 95% CI 0.90 – 1.10) for home-based versus hospital-based monitoring. Very preterm birth only occurred once in the home-based monitoring group. The mean birth weight was 3504.0 (SD 47.7) for the home-based monitoring group versus 3532.1 (SD 48.1) for the hospital-controlled monitoring group. We found no significant differences in LGA (20/146 versus 18/148, RR 1.00, 95% CI 0.90 – 1.10) and SGA (12/146 versus 12/148, RR 1.00, 95% CI 0.90 – 1.10) for home-based versus hospital-based monitoring. Also, no differences were found in HDP, PE, abnormal placentation, GDM, hospital admission during pregnancy and congenital anomaly. One neonatal death due to pulmonary hypoplasia occurred in the home-based monitoring group after very PTB.

Limitations, reasons for caution: The outcomes of HDP, PE, abnormal placentation, GDM and hospital admission during pregnancy were patient-reported and confirmed by hospital-files after contacting the participating centers.

Wider implications of the findings: NC-FET is the preferred treatment in women with ovulatory cycles undergoing FET. When home-based monitoring is compared to hospital-controlled monitoring in NC-FET we found no difference in obstetric or neonatal outcomes.

O-199 Imprinting disorders in singletons conceived by assisted reproductive technology in Sweden

M. Ye[12], A. Palomares[1], E. Iwarsson[34], K. Rodriguez-Wallberg[15], S. Öberg[2]

[1]*Karolinska Institutet, Department of Oncology and Pathology, stockholm, Sweden*
[2]*Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, stockholm, Sweden*
[3]*Karolinska Institutet, Department of Molecular Medicine and Surgery, stockholm, Sweden*
[4]*Karolinska University Hospital, Department of Clinical Genetics, stockholm, Sweden*
[5]*Karolinska University Hospital, Department of Reproductive Medicine, stockholm, Sweden*

Study question: Is singleton birth from assisted reproductive technology (ART) associated with imprinting disorders (IDs) independent of parental infertility and other background factors?

Summary answer: Singletons conceived using intracytoplasmic sperm injection (ICSI) and frozen embryos have higher risks of Beckwith-Wiedemann syndrome (BWS), Prader-Willi syndrome (PWS) and Silver-Russell syndrome (SRS).

What is known already: Previous studies have suggested elevated risk of IDs in children conceived with ART compared with children conceived with spontaneous conception (SC). It is not clear to what extent the observed associations could be explained by parental infertility and related risk factors. Knowledge on specific ART procedures and their association with IDs is also limited.

Study design, size, duration: A nationwide register-based cohort study was carried out in which all liveborn singletons in 1997-2017 in Sweden were included with follow-up to 2018.

Participants/materials, setting, methods: Among 1 998 825 singletons, 60 210 were conceived using ART. The International Classification of Diseases (ICD) version 10 was used to identify three distinct ID groups: PWS/SRS, BWS, and central precocious puberty (CPP). Cox regression, combined with inverse probability treatment weights to account for birth year, parity, pregnancy loss history, parental age and country of origin, was used to compare ART singletons with all SC singletons and those born to couples with known infertility.

Main results and the role of chance: A total of 1012 children were diagnosed with the IDs of interest (654 PWS/SRS, 255 BWS, and 109 CPP), and 49 of them were conceived through ART. Compared with all SC singletons, higher risk of PWS/SRS and BWS was observed in ART singletons and the weighted hazard ratios (wHRs) were 1.57 [95% CI, 1.09-2.26] and 2.57 [95% CI, 1.60-4.12], respectively. The elevated risks remained when comparison was restricted to SC singletons of couples with known infertility, though the wHR for BWS was somewhat attenuated (1.87, 95% CI: 1.04-3.36). No difference in risk of CPP was observed between singletons conceived with and without ART irrespective of parental infertility. Further subgroup analysis revealed that ICSI in combination with frozen embryo transfer was responsible for the higher risks of PWS/SRS (wHR 6.32, 95% CI: 3.34-11.95) and BWS (wHR 9.04, 95% CI: 4.34-18.82).

Limitations, reasons for caution: The use of the Swedish ICD-10 did not allow distinction of PWS and SRS. The number of CPP cases in ART singletons was too small (N = 3) to make inference.

Wider implications of the findings: This study found that ART-conceived singletons, particularly those conceived using ICSI and frozen embryos, had a higher risk of IDs independent of parental infertility. However, the underlying mechanism is not clear, and the role of type and severity of infertility warrants further investigation.

[6]*Copenhagen University Hospital, Department of Neonatology- Rigshospitalet, Copehagen, Denmark*
[7]*Copenhagen University Hospital, Department of Clinical Medicine, Copenhagen, Denmark*

Study question: Is cardiometabolic health in children conceived after frozen embryo transfer (FET) different from children conceived after fresh embryo transfer (fresh-ET) and natural conception (NC)?

Summary answer: FET-children had similar anthropometrics, glucose- and lipid profile in childhood compared to fresh-ET and NC. Blood pressure was higher in FET-girls compared to fresh-ET-girls.

What is known already: Children conceived after assisted reproductive technology (ART) with FET are more often born large-for-gestational age (LGA) while children born after fresh-ET are at risk of being small-for-gestational age (SGA).In general, children born LGA or SGA are at increased risk of obesity, diabetes and cardiovascular disease later in life. Smaller studies on the whole ART-population have raised concerns about premature vascular aging, increased risk of insulin resistance and higher blood pressure. The long-term cardiometabolic health of children born after ART and especially FET is scarcely explored.

Study design, size, duration: This study was part of the large cohort study "Health in Childhood following Assisted Reproductive Technology" (HiCART) which included 606 singletons (292 boys) born between December 2009 and December 2013: 200 children were conceived after FET; 203 children were conceived after fresh-ET; and 203 children were conceived naturally and matched for birth year and sex. The study period lastet from January 2019 to September 2021.

Participants/materials, setting, methods: The children were 7-10 years of age at examination and underwent a clinical examination with anthropometric measurements, pubertal staging and blood pressure measurement. Furthermore a whole-body dual-energy x-ray absorptiometry-scan (DXA) was performed and a fasting blood sample was drawn. Anthropometric measurements and blood pressure were converted to standard deviation scores (SDS) using a Danish reference. The three study groups were compared pairwise using univariate linear regression model.

Main results and the role of chance: Data is presented as mean (SD). Children conceived after FET had significantly higher birth weight (SDS) (0.20 SDS (1.09)) compared to children conceived after fresh-ET (-0.22 SDS (1.00), mean difference: 0.42 SDS (95% CI: 0.21; 0.62)) and NC-children (-0.16 SDS (1.09), mean difference: 0.35 SDS (95% CI: 0.14; 0.57)).

At 7-10 years height (SDS), weight (SDS) and BMI (SDS) were similar between the groups. Fat percentage (DXA) and waist-to-height ratio were also comparable between the groups.

Markers of glucose metabolism were similar in the groups including fasting glucose, C-peptide, HbA1c and insulin resistance (HOMA-IR). Lipid profiles including, cholesterol, LDL and HDL were also similar.

Blood pressure was comparable between the three groups, but stratified on sex girls conceived after FET had significantly higher systolic blood pressure (SDS) (0.75 SDS (0.84)) compared to girls concieved after fresh-ET (0.49 SDS (0.61), mean difference: 0.25 SDS (95% CI: 0.05; 0.45)) and significantly higher diastolic blood pressure (SDS) (FET: 0.54 SDS (0.57), fresh-ET: 0.38 (0.58), mean difference: 0.16 SDS (0.00; 0.31)). Puberty had started in 17% of the girls, equally distributed in the three groups.

Limitations, reasons for caution: As the participation rate was between 18-42% in the three groups, selection bias cannot be excluded. We currently do not have information regarding endometrial preparation protocol in the FET-cycles which may bias the results. Due to multiple testing type I errors cannot be excluded.

Wider implications of the findings: Higher birth weight in children conceived after FET did not translate into differences in anthropometrics, glucose- or lipid profile in children ages 7-10 years. However, the higher systolic- and diastolic blood pressure (SDS) found in girls concieved after FET compared to fresh-ET is of concern and should be further explored.

O-201 Growth of singletons born after frozen embryo transfer until early adulthood: a Finnish register study

A. Terho[12], A. Tiitinen[3], J. Salo[24], H. Martikainen[5], M. Gissler[67], S. Pelkonen[12]

[5]University of Oulu, Department of Obstetrics and gynaecology, Oulu, Finland
[6]Finnish Institute for Health and Welfare, Department of Knowledge Brokers, Helsinki, Finland
[7]Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden

Study question: Does the growth of children born after frozen embryo transfer (FET) differ from those born after fresh embryo transfer (ET) or natural conception (NC)?

Summary answer: Boys born after FET have a higher risk of overweight compared to fresh ET.

What is known already: FET is associated with a higher mean birth weight and an increased risk of large-for-gestational-age (LGA) compared to fresh ET and NC, thus raising questions of possible growth disturbances later in life. Previous studies on early childhood growth after FET have reported partly contradictory results. Moreover, data on the adolescent growth after FET are scarce, reporting no significant differences.

Study design, size, duration: This observational cohort study, based on national population-based registers, includes 1825 and 2933 singletons born after FET and fresh ET in Oulu and Helsinki city areas in Finland between 1995 and 2006. A 10% sample of NC controls ($n = 31\,136$) from the same birth years, matched for area of residence, was obtained from the Finnish Medical Birth Register. Growth data were obtained from the Register of Primary Health Care visits.

Participants/materials, setting, methods: Mean heights, weights, and body mass indices (BMI) were compared between the groups, stratified by sex, between ages 7 and 18, using general linear model. The proportions of overweight (age- and sex-adjusted ISO-BMI for children ≥ 25) were analyzed using multiple linear regression, adjusting for birth year, preterm birth, maternal age, parity, and socioeconomic status. Additionally, the odds for overweight were calculated for all ages combined, adjusting for multiple measurements using generalized estimating equations.

Main results and the role of chance: Growth measurements for each age were available for 5.9-30.6% of boys and 4.7-29.5% of girls. The mean and median number of measurements was three per child. No significant differences in height were found between FET and fresh ET. FET boys were significantly taller compared to NC between ages 11 and 14. For boys, the mean proportions of overweight for FET, fresh ET and NC were 28%, 22% and 26%, respectively ($p < 0.001$ for FET vs fresh ET, $p = 0.014$ for FET vs NC and $p < 0.001$ for fresh ET vs NC). For all ages combined, the adjusted odds ratio (aOR) of overweight was 1.14 (95% CI 1.02-1.27) for FET compared to fresh ET, and 1.08 (95% CI 0.99-1.18) for FET compared to NC. For girls, the mean proportions of overweight for FET, fresh ET and NC were 18%, 19% and 22% ($p = 0.169$ for FET vs fresh ET, $p < 0.001$ for FET vs NC and $p < 0.001$ for fresh ET vs NC). For all ages combined, the aOR of overweight was 0.92 (95% CI 0.81-1.06) for FET compared to fresh ET and 0.89 (95% CI 0.80-0.99) for FET compared to NC.

Limitations, reasons for caution: Unfortunately, we were not able to adjust for parental anthropometric characteristics. The growth data were not available for the entire cohort, and the proportion of children measured at the start and end of the follow-up was limited. Mainly cleavage stage embryos were transferred, and slow freezing was used.

Wider implications of the findings: The lack of significant height differences between FET and fresh ET offers reassurance of the safety and feasibility of FET. However, the risk of overweight among FET boys warrant further research as to verify the results in larger cohorts, and further investigate the mechanisms that explain this gender-specific finding.

O-202 Early reproductive outcomes of the first birth cohorts conceived with in-vitro fertilisation in Sweden

A.S. Oberg[1], A. Nyman[2], A. Ezra[3]

[1]Karolinska Institutet, Department of Medical Epidemiology & Biostatistics, Stockholm, Sweden
[2]National Board of Health and Welfare, Analysis Unit, Stockholm, Sweden
[3]Hudiksvall Hospital, Department of Obstetrics and Gynecology, Hudiksvall, Sweden

Study question: Are early reproductive outcomes of individuals conceived with IVF different from the general population or from spontaneously conceived individuals born to couples with infertility?

Summary answer: The first birth cohorts from IVF were more likely to experience infertility and use assisted reproduction also when accounting for parental factors and infertility

What is known already: In-vitro fertilisation has helped countless couples overcome involuntary childlessness, but little is yet known of the reproductive outcomes of their offspring. Deviations could occur as a result of the transmission of, or reaction to, parental traits and behaviors, or adverse effects of the procedures. A few small studies of young adults conceived with intra-cytoplasmic sperm injection due to male factor infertility have indicated lower sperm quantity (but not quality) compared to spontaneously conceived males, and no differences in reproductive hormones or antral follicle count in females.

Study design, size, duration: This nation-wide cohort study considered all individuals in the Swedish Medical Birth Register, born between 1985 and 1996 (N = 1,291,795). Linkage of population-registers allowed prospective follow-up of potential reproductive outcomes, migration from Sweden or death, until the end of 2017.

Participants/materials, setting, methods: Parental infertility and IVF use was identified from maternal self-report and IVF-clinic reporting to the Medical Birth Register, which was also used for outcome ascertainment, along with registers over family relations, outpatient specialist care, and assisted reproduction. Individuals conceived with IVF were compared to spontaneously conceived individuals of the same age. Comparisons were also adjusted for parents' age, education and country of origin and further restricted to only concern individuals whose parents experienced infertility.

Main results and the role of chance: Compared to spontaneously conceived of the same age, individuals conceived with IVF were less likely to have had any biological children across all studied birth cohorts (Hazard ratio (HR) 0.67 95% Confidence interval (CI) 0.62–0.74 overall), but adjustment for parental factors and comparison to individuals with parental infertility attenuated the differences to the null. Among individuals followed until at least age 30, those that had been conceived with IVF were more likely to have received a diagnosis of infertility (HR 2.03, 95% CI 1.15–3.58), also after adjustment for parental factors (HR 2.08, 95% CI 1.18–3.66) and restriction with respect to parental infertility (HR 1.82, 95% CI 1.03–3.24). While there was no substantial difference in mean age, the first recorded birth was more likely to have been preceded by infertility and IVF assistance when individuals had been conceived with IVF themselves (Odds ratio (OR) 2.89, 95% CI 1.47–5.66 and OR 3.83, 95% CI 1.48-9.93 respectively in adjusted comparison to individuals with parental infertility). Corresponding elevated risks were not observed in any of the birth cohorts for which follow-up did not extend beyond their 20s (born 1988-1996).

Limitations, reasons for caution: Since not even the first IVF birth cohorts have completed their expected reproductive period, these findings merely represent an indication of the early reproductive outcome of the first generation conceived with IVF in Sweden. Information on type and severity of parental infertility was not available.

Wider implications of the findings: Finding the earliest birth cohorts conceived with IVF at elevated risk of infertility and of using IVF for their first birth, also when accounting for parental infertility, stresses the need for further monitoring as more cohorts enter and pass through the expected reproductive period.

Study question: What is the optimal work-up to establish the diagnosis of unexplained infertility, based on the best available evidence in the literature?
Summary answer: The ESHRE Guideline on Unexplained Infertility provides 35 recommendations on the diagnosis of unexplained infertility.
What is known already? The diagnosis of unexplained infertility is made when no abnormalities of the female and/or male reproductive systems are clearly identified. UI is inevitably a diagnosis by exclusion, after "standard" investigations. However, a real standardization of the diagnostic work-up is still lacking.
Study design, size, duration: The guideline was developed according to the structured methodology for the development of ESHRE guidelines. First, a group of experts formulated the key questions. Literature searches and assessments were then performed. Papers written in English and published up to 24 October 2022 were included in the review. Prior to publication, the guideline was reviewed by independent international reviewers.
Participants/materials, setting, methods: Based on the collected evidence, recommendations were formulated and discussed until consensus was reached within the guideline group. A stakeholders' review was organized after the finalization of the draft. The revised version was approved by the guideline group and the ESHRE Executive Committee.
Main results and the role of chance: This guideline aims to help clinicians in delivering the optimal care for couples with unexplained infertility. Since unexplained infertility is a diagnosis of exclusion, this lecture will focus on the diagnostic procedures that couples should/could go through during the infertility work-up, and will analyse the need for additional diagnostic tests to establish the diagnosis of unexplained infertility. The guideline has been in stakeholder review and is prepared for submission in 2023.
Limitations, reasons for caution: Most diagnostic tests and interventions in couples with unexplained infertility are not well studied. For a large proportion of these tests, evidence was very limited and of very low quality. Further studies are definitely needed in this field, possibly providing reliable data for revisiting the current recommendations.
Wider implications of the findings: Based on the best available evidence, the guideline provides clinicians with clear advice on how to optimize the diagnostic approach to couples with unexplained infertility. In addition, a list of research recommendations is included to prompt further studies in the field.
Study funding/competing interest(s) The guideline was developed and funded by ESHRE, that covered expenses associated with the guideline meetings, with the literature searches and with the dissemination of the guideline. The guideline group members did not

O-204 Treatment of unexplained infertility: IUI for all?

S. Bhattacharya[1]

[1]University of Aberdeen, School of Medicine- Medical Sciences & Nutrition, Aberdeen, United Kingdom

Study question: What is the recommended management for couples presenting with unexplained infertility, based on the best available evidence in the literature?
Summary answer: The ESHRE Guideline on Unexplained infertility makes 19 recommendations on treatment of couples with unexplained infertility.
What is known already?: Unexplained infertility (UI) is diagnosed in the absence of any abnormalities of the female and/or male reproductive systems after "standard" investigations. The management of UI is traditionally empirical. The efficacy, safety, costs, and risks of treatment options have not been subjected to robust evaluation.
Study design, size, duration: The guideline was developed according to the structured methodology for the development of ESHRE guidelines. Following formulation of key questions by a group of experts, literature searches and assessments were undertaken. Papers written in English and published up until 24 October 2022 were included. Prior to publication, the guidelines were reviewed by independent international reviewers.
Participants/materials, setting, methods: Based on the available evidence, recommendations were formulated and discussed until consensus was reached within the guideline group. A stakeholder review was organized after finalization of the draft. The final version was approved by the guideline group and the ESHRE Executive Committee.
Main results and the role of chance: This guideline aims to help clinicians provide the best care for couples with unexplained infertility. The first-line treatment for couples with unexplained infertility was deemed to be intrauterine insemination (IUI) in combination with ovarian stimulation. This lecture will focus on the rationale behind this recommendation and the place of additional and alternative options for the treatment of unexplained infertility.

The guideline has been in stakeholder review and is prepared for submission in 2023.

Limitations, reasons for caution: Most interventions in couples with unexplained infertility have not been subjected to robust evaluation. For a large proportion of these treatments, evidence was very limited and of very low quality. More evidence is required, and the results of future studies may require the current recommendations to be revised.
Wider implications of the findings: The guideline provides clinicians with clear advice on best practices in the care of couples with unexplained infertility, based on the best evidence currently available. In addition, a list of research recommendations is provided to stimulate further studies in the field.
Study funding/competing interest(s): The guideline was developed by ESHRE which funded the guideline meetings, the literature searches and dissemination. The guideline group members did not receive any financial incentives; all work was provided voluntarily.

[6]*University of Padova, Department of medicine, Padova, Italy*

Study question: What is the impact of sperm parameters and paternal age on all embryological and clinical outcomes during ICSI-cycles with aneuploidy testing?

Summary answer: Reduced basal/post swim-up motility and patients with concentration+morphology+motility <5th-percentile (based on WHO-2021) are associated with poorer embryological outcomes and cumulative-live-birth-rate per concluded PGT-A cycle.

What is known already: Previous studies reported an association between oligoasthenoteratozoospermia (OAT), obstructive azoospermia (OA) and non-obstructive azoospermia (NOA) and poorer fertilization/blastulation rates, but no impact on euploidy rates at the blastocyst stage. Similarly, the clinical outcomes were mostly independent from sperm characteristics when euploid blastocysts are transferred. The data about paternal age effect are controversial, varying between absent and severe embryological/clinical impact. Moreover, little is known about the association between each semen analysis parameters and embryological/clinical outcomes. Lastly, most of the evidence to date was based on WHO 2010 criteria, recently updated by WHO 2021, and did not mention cumulative-live-birth-rates (CLBR) per cycle.

Study design, size, duration: Retrospective study at a single private center involving 4013 ICSI+PGT-A cycles with own-oocytes conducted by 3101 couples (2013-2021). The primary embryological outcome was euploid-blastocyst-rate (EBR) per cohort of inseminated oocytes. The primary clinical outcome was CLBR per concluded cycle (i.e., LB achieved or no transferable/all transferred blastocysts). Intermediate embryological/clinical outcomes were also tested. All parameters were analyzed as continuous variables. For some analyses we categorized paternal age (<38/38-44/>44 years) and sperm factor (WHO-2021 parameters<5th percentile).

Participants/materials, setting, methods: GnRH-antagonist ovarian-stimulation, ICSI, trophectoderm biopsy without zona-pellucida drilling in day3, qPCR/NGS-based analysis to report non-mosaic aneuploidies (segmental aneuploidies reported from 2017 onwards; N = 1991 cycles) and vitrified-warmed euploid single-blastocyst-transfers were conducted. Semen analysis (volume, concentration, total sperm per ejaculate, basal/post swim-up motility, morphology), sperm characteristics (ejaculated/FNA/TESE; fresh/frozen), DNA-fragmentation-index (DFI, outlined via Tunel-test; N = 188 cycles), paternal BMI and age were investigated for their association with embryological/clinical outcomes adjusted for confounders via linear/logistic regressions.

Main results and the role of chance: Maternal and paternal age were 38.9 ± 3.2(range:23-45) and 41.9 ± 5.7(25-72) years, 10 ± 6.3(1-44) cumulus-oocyte-complexes were retrieved and 7.3 ± 4.6(1-32) metaphase-II oocytes inseminated. Cycles showing all parameters >5th-percentile were 47.1%(N = 1890), concentration<5th-percentile were 3.7%(N = 149), motility<5th-percentile were 3.9%(N = 155), morphology<5th-percentile were 10.1%(N = 405), concentration+motility<5th-percentile were 1.7%(N = 70), concentration+morphology<5th-percentile were 6.2%(N = 248), motility+morphology<5th-percentile were 5.0%(N = 70), concentration+motility+morphology<5th-percentile were 19.9%(N = 797), OA and NOA were 1.4%(N = 56) and 1.0%(N = 41), respectively. The only confounder upon EBR per cohort of metaphase-II oocytes was maternal age. Only basal/post swim-up motility was associated with this outcome. When categorized, only concentration+morphology<5th-percentile (-2.7%,95%CI -5.1 to -0.3%, adjusted-p=0.03), concentration+morphology+motility<5th-percentile (-4.0%,95%CI -5.5 to -2.6%, adjusted-p<0.01), OA (-5.5%,95%CI -10.3 to -0.7%, adjusted-p=0.03) and NOA (-5.8%,95%CI -11.4 to -0.1%, adjusted-p=0.05) showed significantly poorer results. Maternal age and number of metaphase-II oocytes were the confounders upon the chance to obtain ≥1 euploid blastocyst and ≥1 LB among concluded cycles. Only basal/post swim-up motility was associated with this outcome. When categorized, only concentration+morphology+motility<5th-percentile showed significantly lower chances (multivariate-OR:0.74,95%CI 0.61-0.90, adjusted-p<0.01 and multivariate-OR:0.74,95%CI 0.59-0.92, adjusted-p<0.01). No association was reported between semen parameters/sperm factor categories and 1PN/3PN rates, day5-7 blastocyst-rate, morphological quality, outcomes per euploid transfer. Paternal age categories were associated with day5-blastocyst (N = 1131/3308,34.2%, N = 1179/3644,32.4%, and N = 919/3127,29.4%) and AA-blastocyst rates (N = 1732/3308,52.4%, N = 1815/3644,49.8%, and N = 1387/3127,44.4%) in men <38/38-44/>44 years, respectively (p < 0.01).

Limitations, reasons for caution: Some confounders were unbalanced among the study groups but accounted for in linear/logistic regressions. 9% of the cycles were not concluded by the time of abstract drafting. The sample size in the groups of surgically-retrieved sperm is limited, in part because NOA patients due to genetic causes were not included.

Wider implications of the findings: By comprehensively accounting for sperm factor characteristics, this report provides reproductive professionals with useful figures to counsel infertile couples about their chance of success during IVF. These estimates are useful for the decision-making process regarding the most effective clinical strategies to apply. Further studies including more NOA/OA patients are warranted.

P-047 A novel mutation of DRC1 gene causes multiple morphological abnormalities of the sperm flagella and male infertility in humans

T. Fu[1,2], H. Liao[1,2], S. Long[1,2], X. Tang[1,2], G. Huang[1,2], W. Han[1,2], W. Liu[1,2], T. Lin[1,2]

[1]*Women and Children's Hospital of Chongqing Medical University, Center for Reproductive Medicine, Chongqing, China*
[2]*Chongqing Health Center for Women and Children, Center for Reproductive Medicine, Chongqing, China*

Study question: Can novel mutations of *DRC1* gene affect the sperm morphology in humans and how about the outcomes of assisted reproductive therapy of the affected patients?

Summary answer: An infertile man with multiple morphological abnormalities of the sperm flagella caused by *DRC1* biallelic mutations has good outcomes of fertility after intracytoplasmic sperm injection.

What is known already: The nexin-dynein regulatory complex (N-DRC) functions by linking neighboring doublet microtubules within motile cilia and flagella, stabilizing the axonemal structure and thereby regulating ciliary motility. As a core of N-DRC protein, the disruptions of *DRC1* gene have been identified to cause multiple morphological abnormalities of the sperm flagella (MMAF) and male infertility in humans and mice. *DRC1* mutations usually

resulted in decreased flagellum axoneme stability, thereby causing flagellar structural disorder.

Study design, size, duration: The 35 patients with MMAF were recruited from the center for reproductive medicine from August 2019 to June 2022. They were diagnosed with primary male infertility caused by abnormal morphologies of sperm flagella and decreased sperm motility. Genetic testing, pedigree analysis, sperm morphological analysis, functional assays, and assisted reproductive therapy were performed in 2022.

Participants/materials, setting, methods: We identified and confirmed the *DRC1* mutation through a 22-gene next-generation sequencing panel and sanger sequencing. Papanicolaou-staining, scanning electronic microscope, and transmission electronic microscope were performed to reveal the changes of sperm morphology and ultrastructure. Immunostaining was conducted to show the effect of *DRC1* mutation on the expression and localization on sperm structural proteins. After the ovarian stimulation, a time-lapse monitoring system was applied for the assisted reproductive therapy of *DRC1* mutant patient.

Main results and the role of chance: Biallelic mutations in *DRC1* were identified in a 39-years-old proband who suffered from primary infertility for 9 years due to severe asthenoteratozoospermia. Pedigree analysis of the non-consanguineous family manifested an autosomal recessive inheritance pattern. Papanicolaou-staining, scanning and transmission electronic microscopy showed the abnormalities of sperm flagella and severe disorganization of the axoneme in *DRC1*-deficient male compared to control subject. Immunostaining with sperm-specific markers, TOM20, DNAI1, and DNALI1, showed the composite changes of flagella morphology and molecular components. After intracytoplasmic sperm injection (ICSI), the rate of fertilization was 71.4% (5/7), the rate of embryo cleavage was 100% (5/5), the rate of transferable embryo was 60% (3/5), respectively. Following frozen-thawed embryo transfer, the wife of the proband became pregnant.

Limitations, reasons for caution: Additional cases are needed to investigate the gene-disease relationship between *DRC1* mutations and male infertility owing to abnormal sperm morphology and motility.

Wider implications of the findings: This study expands the mutant spectrum of *DRC1* and describes a good fertility outcome of assisted reproduction therapy with ICSI for the *DRC1* mutant patient. Together with the available information regarding male infertility, it provides new information for the genetic diagnosis and counseling of MMAF in the future.

P-045 Effects of seminal BPA levels on human sperm parameters and gene expression

O. Davis[1], R. Sabry[1], J. Acosta[1], A. Lagunov[2,3], M. Ghaffarzadeh[4], L. Favetta[1]

[1]*University of Guelph, Biomedical Sciences, Guelph, Canada*
[2]*CCRM Toronto/ Hannam Fertility Centre, ART Lab, Toronto, Canada*
[3]*CCRM IVF Network, ART Lab, Lone Tree, U.S.A.*
[4]*CCRM Toronto/ Hannam Fertility Centre, Andrology Lab, Toronto, Canada*

Study question: Are high BPA levels in human seminal fluid associated with low sperm metrics and changes in gene expression?

Summary answer: A trend towards an inverse relationship between seminal BPA and sperm count was observed. Expression of androgen receptor mRNA was down-regulated with high BPA exposure.

What is known already: Bisphenol A (BPA) is a widespread industrial chemical, used as the key monomer of polycarbonate plastics and epoxy resins. While some countries have introduced bans/stringent regulation for BPA, it continues to be widely used especially in North America, where its use is only limited in baby products. BPA has been detected in human seminal fluid and has been correlated with decreased sperm counts and motility - crucial factors in determining male fertility, which continue to decrease. We have demonstrated that *in vitro* BPA exposure can reduce motility, mitochondrial membrane potential, and capacitation in mature bovine spermatozoa.

Study design, size, duration: In collaboration with CCRM, Toronto, seminal fluid samples were collected from 90 patients undergoing fertility assessment between 2021 and 2023. Typical evaluations such as sperm counts, motility, and morphology were recorded by the clinic (following WHO guidelines). Samples were then shipped to the University of Guelph for further investigations. Information on outcomes for patients who underwent subsequent IVF cycles like fertilization rates and pregnancy rates were also recorded at the clinic.

Participants/materials, setting, methods: At the University of Guelph, seminal BPA levels were measured through an enzyme-linked immunosorbent assay (ELISA; My BioSource), then compared to sperm metrics obtained by the clinic. Next, a GeNorm analysis was performed to determine the most stable reference genes for subsequent qPCR analysis. The relative mRNA expression of three key genes related to male reproduction (androgen receptor (AR), cyp17a1 and cyp11a1) were quantified and compared between groups with high and low BPA content.

Main results and the role of chance: BPA concentrations in the seminal fluid samples ranged between 0-3000 pg/mL, with most samples containing 35-1000 pg/mL. When samples were graphed according to increasing BPA levels, no relationships were observed between BPA and motility or morphology rates. However, a negative trend between BPA and sperm count was detected, although this was not significant. Samples were then divided into high- (total 15 samples with >700 pg/mL) and low- (total 15 samples with <100 pg/mL) BPA content groups. The GeNorm M value indicated that HPRT1 and HMBS were the most stable reference genes across the groups. qPCR analysis on three biological replicates in technical triplicates showed that androgen receptor mRNA expression was significantly higher in sperm exposed to low seminal BPA compared to the high BPA exposure group ($p = 0.03913$). This finding is particularly interesting as AR expression has previously been positively correlated with sperm count, motility and morphology. cyp17a and cyp11a mRNA expression was undetectable in human spermatozoa under our experimental conditions. Future steps include increasing the sample size to increase the power of the correlation studies between sperm quality parameters and ART success rates. Furthermore, other fertility-related genes will be investigated at both the mRNA (qPCR) and protein levels (flow cytometry).

Limitations, reasons for caution: Relatively small sample size; duration of study must be extended to gain information on outcomes of ART cycles; many samples in the mid-range of BPA are excluded from gene expression studies.

Wider implications of the findings: These results can ultimately display a relationship between BPA exposure and male fertility and provide further insights into the molecular mechanisms through which BPA exerts its effects. Ultimately, this research can drive changes to guidelines/exposure limits for BPA, especially in North America.

Trial registration number: not applicable

P-088 The Paternal Clock: Shedding Light on the Relationship Between Paternal Age and Sperm DNA Fragmentation

E. Kadoch[1], A. Tadevsoyan[1], A. Zini[1], S. Phillips[1], F. Bissonnette[1], I.J. Kadoch[1]

[1]*ovo clinic, ovo r&d, Montreal, Canada*

Study question: What is the impact of advanced paternal age (APA) on sperm DNA fragmentation index (DFI)?

Summary answer: Sperm DFI levels remain relatively stable until the age of 35 and increase progressively beyond that age.

What is known already: APA can have a negative impact on male fertility and the health of offspring. Previous studies have shown that APA is linked to poor conventional sperm parameters, including decreased semen volume, sperm count, motility, morphology, as well as poor sperm DNA integrity. Additionally, APA has been associated with reduced natural or assisted reproduction and perinatal outcomes and a higher risk of genetic and chromosomal abnormalities in the offspring.

Study design, size, duration: A retrospective cohort study of 4250 consecutive semen samples from men undergoing infertility evaluation at the OVO clinic, in Montreal, Canada, between April 2016 and December 2022. Participants were stratified into seven age groups: <26 (n = 36; 0,8%), 26-30 (n = 500; 11,8%), 31-35 (n = 1269; 29,9%), 36-40 (n = 1268; 29,8%), 41-45 (n = 732; 17,2%), 46-50 (n = 304; 7,2%), >50 years (n = 141; 3,3%). The mean age was 37.4 ± 6.4 years (range 18-71 years).

Participants/materials, setting, methods: The study was population-based and included male patients from all ages, ethnicities, and medical histories. Semen samples were collected after 2-3 days of abstinence. For patients who underwent more than one DFI testing, only the first sample was included, and any duplicates were excluded. DFI was evaluated by flow-cytometry based TUNEL assay using the APO-Direct Kit. Data were analyzed using one-way ANOVA and T3 Dunnett post-hoc multiple comparison test, as well as Pearson's correlation coefficient.

Main results and the role of chance: The results show a significant positive correlation between %DFI and age ($r = 0.19$, $p < 0.001$). Mean %DFI levels were relatively stable in men aged <26 to 35 years (17.9%, 18.1% and 18.1% in men aged <26, 26-30 and 31-35, respectively), with %DFI increasing progressively beyond age 35 (20.7%, 22.5%, 25.7% and 27.9% in men aged 36-40, 41-45, 46-50 and >50, respectively). The mean %DFI in the 36-40 age group was significantly higher than in the 31-35 age group ($p < 0,001$). Our study has uncovered that %DFI follows an exponential curve starting at age 35, indicating that the %DFI accelerates significantly as men age beyond their mid-30s.

Limitations, reasons for caution: This retrospective analysis has inherent limitations that may introduce confounding variables. The patient clinical background, such as medical history and lifestyle factors was not assessed. Also, the studied cohort consisted of a population under investigation for infertility and may not be representative of the general male population.

Wider implications of the findings: The study demonstrates the age-related increase in sperm %DFI and suggests that there may be an age cut-off below which sperm %DFI is stable and beyond which sperm %DFI increases. This information may be useful to medical specialists that offer sperm DNA testing to infertile couples.

P-014 Inhibition of mitochondrial uncoupling proteins irreversibly arrests human spermatozoa motility

D. Carrageta[1], L. Freire-Brito[1], B. Guerra-Carvalho[1], J. Ribeiro[1], B. Monteiro[1], A. Barros[2], P. Oliveira[3], M. Monteiro[4], M.G. Alves[1]

[1]ICBAS - School of Medicine and Biomedical Sciences- University of Porto- Porto-Portugal, Laboratory of Physiology- Department of Immuno-physiology and Pharmacology, Porto, Portugal
[2]Centre for Reproductive Genetics Prof. Alberto Barros- Porto- Portugal, Department of Genetics, Porto, Portugal
[3]University of Aveiro, Chemistry Department, Aveiro, Portugal
[4]ICBAS - School of Medicine and Biomedical Sciences- University of Porto- Porto-Portugal, Department of Anatomy, Porto, Portugal

Study question: Are mitochondrial uncoupling proteins (UCPs) expressed in human spermatozoa and if yes, what is their role?

Summary answer: UCP1, UCP2, and UCP3 are expressed in human spermatozoa. The inhibition of UCPs irreversibly arrests human spermatozoa motility without compromising viability.

What is known already: UCPs are expressed in the mitochondrial inner membrane, where they act as channels between the intermembrane space and the matrix. Six UCP homologs had already been identified in mammals (UCP1-6). UCPs act as regulators of reactive oxygen species (ROS) production, general cellular redox state, and mitochondrial function. The altered expression or function of UCPs is positively linked with the onset of metabolic diseases, such as obesity and diabetes mellitus. Male infertility is closely related to metabolic diseases since the testis is susceptible to metabolic alterations and oxidative stress, however, the expression and function of UCPs in human spermatozoa are unknown.

Study design, size, duration: We performed a control-versus-treatment study. High motility spermatozoa were isolated through density gradient centrifugation from human normozoospermic seminal samples (n = 16) and incubated with genipin, a selective UCP inhibitor (0, 0.5, 5, and 50 μM), for 3 h at 37 °C. Cells and culture media were collected for analysis.

Participants/materials, setting, methods: UCP1-3 protein expression was detected by western blot and immunofluorescence. After UCPs inhibition, spermatozoa viability and motility were assessed. Mitochondrial membrane potential and ROS production were evaluated. Media were collected and the metabolic profile and antioxidant potential were analysed by ^{1}H-NMR and FRAP, respectively.

Main results and the role of chance: We were able to identify the expression of UCP1, UCP2, and UCP3 in human spermatozoa. UCP1-3 are mainly located at the equatorial segment of the head, whereas UCP1 and UCP2 are also expressed at the spermatozoa midpiece, where mitochondria are located. The inhibition of UCPs by 50 μM genipin, resulting in the UCP3 inhibition, led to the complete and irreversible loss of motility that persisted despite washing or incubation with theophylline, a cAMP activator. These effects were associated with decreased mitochondrial membrane potential and lactate production. Interestingly, the loss of motility did not compromise spermatozoa viability. In addition, the inhibition of UCPs led to no alterations concerning ROS production, possibly due to the decreased mitochondrial activity and genipin antioxidant properties.

Limitations, reasons for caution: This is an in vitro study with a relatively small sample size. Genipin is considered a specific yet a general inhibitor of UCPs. The development and use of specific inhibitors for each homolog will further disclose their role in human spermatozoa motility and bioenergetics.

Wider implications of the findings: UCPs are expressed in human spermatozoa. UCPs are important regulators of human spermatozoa motility and metabolism. The discovery and characterization of UCPs' role in human spermatozoa open the path for studies on ROS-related pathways and bioenergetics physiology of human spermatozoa.

O-205 Poor mitochondrial metabolism impairs meiosis and contributes to reduced oocyte maturation rates in patients with advanced maternal age

S. Pietroforte[1], M. Martins[2], E. Ibañez[3], M. Popovic[1], T. Sanchez[4], R. Vassena[1], D. Sakkas[2], F. Zambelli[1]

[1]EUGIN group, Research and Development, Barcelona, Spain
[2]EUGIN group, BostonIVF, Waltham- Boston MA, U.S.A.
[3]Universitat Autonoma de Barcelona, Department of Cell Biology- Physiology and Immunology, Barcelona, Spain
[4]OPTIVA, fertility, Boston MA, U.S.A.

Study question: Is there a relationship between poor mitochondrial metabolism and impaired meiotic progression of germinal vesicle (GVs) oocytes in women of advanced maternal age (AMA)?

Summary answer: Poor mitochondrial metabolism impairs meiotic progression in human oocytes, contributing to a lower oocyte maturation capacity in women of AMA.

What is known already: High aneuploidy rates and impaired metabolism are characteristic features of AMA oocytes. Studies in mouse suggest that

successful meiotic maturation and metabolic competency may be functionally linked, however this relationship has not been clearly established in human. Metabolic dynamics can be visualized by indirect measurements through mitochondrial staining and quantified more directly using Fluorescence Lifetime Imaging Microscopy (FLIM). This live-imaging approach can generate metabolic timelapse profiles of oocytes throughout meiosis. We performed an extensive characterization of oocyte metabolism in maturing GVs, obtained from both young and AMA patients, to establish the importance of mitochondrial metabolism during meiosis.

Study design, size, duration: A total of 401 GVs from young (≤30 years, n = 264) and AMA (>37 years, n = 137) women were included in the study. GVs were matured in vitro in G2-plus medium for 30 hours. Maturation was determined by the presence of an extruded polar body. Oocytes were used for FLIM (n = 175) and immunofluorescence (IF) analysis (n = 226). Further, mitochondrial metabolism loss of function studies (n = 64) were performed by treating young GVs with 1μM Trifluoromethoxy-carbonylcyanide-phenylhydrazone (FCCP) for 30 minutes.

Participants/materials, setting, methods: The proteins Dihydrolipoamide-S-Acetyltransferase (D-LAT) and Translocase-of-outer mitochondrial-membrane (TOMM20) were analysed in young and AMA oocytes by IF (Arbitrary-Unit, AU) to assess mitochondrial activity and localization, respectively. Fluorescence mean intensities were quantified with ImageJ and compared by t-test; maturation rates were compared by Chi-squared test. FLIM comprehensive metabolism (NADH; FAD^{+}) were taken at GV stage. Different FLIM parameters (fluorescence intensity, fraction bound, short/long lifetime) were evaluated individually and combined into the Redox ratio (NADH intensity/FAD^{+} intensity).

Main results and the role of chance: Mitochondrial staining showed a common pattern in young and AMA GV oocytes, with a uniform localization of mitochondria in the ooplasm (TOMM20) and a subcortical localization of active organelles (D-LAT). These patterns were confirmed by in-live FLIM analysis. The total mitochondria abundance was comparable between AMA and young GV oocytes (intensity of 61674 ± 24322 AU in young, 32186 ± 33414 AU in AMA, p = 0.195), however, active mitochondria were diminished in AMA compared to young GVs both by IF and FLIM (intensity of 78614 ± 58534 AU in young, 12517 ± 10187 AU in AMA, p = 0.003; Redox ratio in young 2e+00 ± 0.15, in AMA 1e+00 ± 0.16, p = 2.969e-05). Notably, young oocytes matured at a significantly higher rate (86.3%; 63/73) than AMA oocytes (62.3%; 38/61; p = 0.002). Moreover, FLIM imaging revealed that GVs with a higher metabolism were more likely to complete meiosis to MII (Redox ratio 2e+00 ± 0.17 in GVs matured to MII, 1e+00 ± 0.18 in non-matured, p = 1.054e-06). Following treatment with FCCP, young GVs showed a similar phenotype to AMA oocytes, with a significant decrease in mitochondrial activity (intensity of 78614 ± 58534 IU in untreated and 11554 ± 16131 IU in treated GVs, p = 0.019), and an associated drop-in maturation rate. Ultimately, only 39.5% (17/43) of the young treated GVs were able to accomplish meiotic maturation.

Limitations, reasons for caution: Maturation rates were assessed by the presence of an extruded PB and variations in spindle assembly timings may have been overlooked. The quantification of mitochondrial activity in loss of function studies was assessed only by IF staining.

Wider implications of the findings: Our findings demonstrate the presence of a functional link between oocyte metabolism and impaired meiosis, which may contribute to the decline of oocyte quality with age. Given that live-metabolic imaging is able to discern GVs that progress through meiosis, this approach may represent a valuable non-invasive tool in oocyte selection.

O-206 Growth hormone supplementation reduces aneuploidy and improves the quality of aged oocytes by activating the JAK2-ERK1/2 pathway

Y. Luo[1], J. Li[1], G. Huang[1]

[1] *Chongqing health center for women and children, Chongqing reproductive and genetics institute, Chongqing, China*

Study question: Does growth hormone (GH) supplementation improves the quality of oocytes in aged mice via reducing aneuploidy?

Summary answer: Daily injections of GH for 8 weeks reduces aneuploidy by activating JAK2-ERK1/2 pathway and improves the quality of oocyte in aged mice.

What is known already: Aging-induced low-quality oocytes, which are mainly caused by aneuploidy, decrease female fertility. However, few treatments are available to improve the poor quality of oocytes in aged women. Age-related decline in GH levels may be related to the insufficient reproductive potential in aged women. Several studies have reported that GH improves assisted reproductive technology outcomes in poor ovarian response patients, although its role is still controversial. In animal models, GH supplementation improved the oocyte quality by enhancing mitochondrial function. However, whether GH reduces the aneuploidy rate in aged oocytes, and if so the underlying mechanisms, are unclear.

Study design, size, duration: The aged (8-month-old) C57BL/6J female mice were used in the study. For the *in vivo* experiments, the aged mice were intraperitoneally injected with GH (GenSci, Changchun, China; 1.6 mg/kg body weight) or an equivalent volume of normal saline for 8 weeks; For the *in vitro* experiments, germinal vesicle (GV) oocytes from aged mice were treated with GH (200 ng/mL) or PBS in M16 medium.

Participants/materials, setting, methods: We counted oocytes by immunohistochemistry to assess ovarian reserve. The expression of growth hormone receptor and mitochondrial genes were measured by quantitative real-time PCR. Time–lapse incubator was utilized to record the developmental potential of early embryos. Immunofluorescence was performed to assess parameters of oocyte quality (mitochondrial functions, spindle/chromosome defects, and DNA damage). Chromosome spread and DNA sequencing were used to analyze aneuploidy rate. We performed quantitative proteomics analysis to identify the potential targets of GH.

Main results and the role of chance: Firstly, we found that GH promoted GHR expression in aged oocytes (30.64 ± 1.70 vs 21.68 ± 1.08, $P < 0.001$). GH ameliorated aging-induced decline in ovarian reserve of aged mice, with increased ovarian index (0.040% ± 0.0031 vs 0.023% ± 0.0019, $P < 0.01$), and number of antral follicles (8.67 ± 1.2 vs 3.33 ± 0.88, $P < 0.05$) compared to the controls. In addition, GH improved the quality of aged oocytes, representing restored mitochondrial functions ($P < 0.05$), decreased DNA damage (23.37 ± 1.76 vs 38.35 ± 2.52, $P < 0.001$) . As expected, GH promoted the fertilization rate (39.9% ± 1.10 vs 14.4% ± 0.62, $P < 0.001$) and early embryo development ($P < 0.01$) of aged oocytes. Of note, GH recovered the spindle/chromosome defects (42.6% ± 2.12 vs 63.9% ± 1.83, $P < 0.01$, and reduced aneuploidy rate (20.9% ± 1.61 vs 39.3% ± 1.84, $P < 0.01$) in aged oocytes. GH activated ERK1/2 expression to decrease aneuploidy rate in aged oocytes. In addition, JAK2 might be involved in the regulation of GH on ERK1/2 expression in aged oocytes. Altogether, GH restored age-related decline in oocyte number, and decreased the occurrence rate of aneuploidy by activating JAK2-ERK1/2 pathway, thereby improving the quality of aged oocytes.

Limitations, reasons for caution: The molecular action mechanism of GH to regulate aneuploidy remains to be determined. Besides, future work should be extended to human oocyte to determine whether this mechanism is conserved between mice and humans

Wider implications of the findings: Our work expounds a theoretical basis for application of GH to improve the fertility of aged women. Besides, the results also feed new ideas for the prevention and treatment of oocyte quality decline in assisted reproductive technology.

O-207 zp1 mutation affects oocyte energy metabolism and leads to oocyte apoptosis

C. Lv[1], H. Xiao[2], D. Guo[2], R.P. Quan[3]

[1]Department of Reproductive Medicine Center-The Third Xiangya Hospital, Central South University-, changsha Hunan, China
[2]Institute of Reproductive & Stem Cell Engineering, School of Basic Medical Science- Central South University-, Changsha.hunan, China
[3]Institute of Reproductive & Stem Cell Engineering, School of Basic Medical Science- Central South University, Changsha.hunan, China

Study question: How does the zp1 variation leads to apoptosis oocytes in antral follicular and infertility in females?

Summary answer: Mutant zp1 induces abnormal pyruvate transport leading to the accumulation of reactive oxygen species (ROS), which activates the mitochondria-mediated apoptosis pathway leading to oocytes apoptosis.

What is known already: Previous research reported a zp1 mutation in human infertility, and we develop a homologous rat strain to investigate the pathogenic effect. The ovaries of homozygous rat posses growing and fully grown oocytes, the oocytes completely lack a zona pellucida. Only 1-2 eggs were recovered from oviducts of per superovulated homozygous rat, and were not surrounded by a zona pellucida thus lost their fertilization capacity in vitro.Further studies showed that the homozygous female rats not only lacked ZP but also TZPs (an important communication bridge between granulosa cells and oocytes), and the caval follicles showed obvious apoptotic signals.

Study design, size, duration: In this study, 10 Sprague-Dawley rats were used at 8 weeks of age (5 wild-type and 5 mutant respectively).

Participants/materials, setting, methods: We used CRISPR/Cas 9-mediated genomic editing technology to develop a rat model carrying the homologous 8bp deleted mutation in Zp1 gene(Zp1mt/mt). The rats were sacrificed by cervical vertebra dislocation and their ovaries were isolated immediately. Then using bulk RNA sequencing of ovaries from Zp1mt/mt and wild-type female rats to identify the differential expression gene between the two groups.The differentially expressed genes enriched from KEGG were verified by qRT-PCR and in vitro functional experiments.

Main results and the role of chance: Total of 293 DEGs were obtained, of which 144 were up-regulated and 149 were down-regulated. The results of biological process showed that up-regulated genes were mainly involved in redox reaction and negative regulation of cell migration.Down-regulated genes are mainly involved in the follicular growth and development,and related to oocyte energy metabolism.

In order to verify the DEG results obtained from RNA sequencing, the differentially expressed gene *Gcgr*, *Plcβ2*, *Aox3* and *Hpgd* enriched from KEGG in cell metabolism were verified by qRT-PCR. The results showed that the differentially expressed gene results were consistent with the expression trend of sequencing data.The results showed that there was no significant difference in the expression of *Pkm* in granulosa cells, while there was a significant difference in the expression of *Pdk4* in Zp1mt/mt oocytes.

For ROS detection, 52 eggs of 4 *Zp1*mt/mt rats and 48 eggs of 6 wide-type rats were analyzed for reactive oxygen species. The results showed that the IOD of mutant eggs was significantly higher than that of wild-type,indicating that ROS content in mutant eggs was significantly increased, which was statistically significant.The detection of apoptotic protein expression in eggs shows that the apoptosis probability of Zp1mt/mt eggs is significantly higher than that ofwild-type.

Limitations, reasons for caution: This study provides more experimental basis and data support for the involvement of ZP in oogenesis, but the effect of ZP deficiency on the dynamic transcriptional regulation of developing oocytes-granulosa cells and the specific molecular mechanism remain to be further explored.

Wider implications of the findings: The work provides key insights into the crucial features of the transcriptional regulation in Zp1 mutant animal ovaries, and offers important clues for exploring the potential mechanism of abnormal oocyte development due to ZP deficiency.

Trial registration number: none

Abstract citation ID: dead093.254

O-208 Maternal spindle transfer restores the developmental competence of in vitro aged oocytes with diminished metabolic activity identified by hyperspectral imaging

N. Costa-Borges[1], A. Parra[2], E. Mestres[1], M. Acacio[1], C. Castello[1], A. Seriola[2], S. Ojosnegros[2], G. Calderón[1]

[1]Embryotools S.L., R&D department, Barcelona, Spain
[2]Institute for Bioengineering of Catalonia IBEC, Bioengineering in Reproductive Health, Barcelona, Spain

Study question: Can the developmental competence of poor-quality oocytes identified by hyperspectral imaging be restored by maternal spindle transfer?

Summary answer: Maternal spindle transfer can be efficiently assisted by hyperspectral imaging to identify and subsequently repair the developmental competence of poor-quality oocytes.

What is known already: Oocyte cytoplasmic dysfunctions (including, but not limited to the mitochondria) are a major cause for poor embryonic development. Given that maternal spindle transfer (MST) allows the replacement of the entire cytoplasm of an oocyte, it is a promising method for the enhancement of oocyte developmental competence. However, accurate diagnostic tools for oocyte quality assessment are lacking. Recently, a novel hyperspectral imaging approach has been shown to classify oocytes non-invasively based on their metabolic profile, which could assist in the evaluation of oocyte developmental potential prior to MST.

Study design, size, duration: Oocytes were obtained from young female mice and analyzed blindly by hyperspectral imaging either immediately after collection (fresh group, n = 122), after overnight culture (*in-vitro* aged group, n = 58) or on a group of MST oocytes (n = 36), where the meiotic spindle from *in-vitro* aged oocytes was transferred into enucleated fresh oocytes. Oocytes were inseminated by ICSI and cultured *in-vitro* individually. Correlations between the oocyte's metabolic profiles and rate of development to the blastocyst stage were performed.

Participants/materials, setting, methods: Oocytes were collected from 6-10 weeks-old superovulated B6CBAF1 females. MST was performed in manipulation medium supplemented with cytochalasin B. After enucleation, karyoplasts were exposed to an inactivated Sendai virus solution to promote membrane fusion. ICSI was performed using a Piezo-Drill actuator. Hyperspectral imaging was done in the near-infra-red regime to avoid photoxicity. Image processing was done using dimensionality reduction, which was then feed to an Akaike Information Criterion algorithm to classify the different metabolic subpopulations.

Main results and the role of chance: Fresh oocytes showed metabolic profiles that significantly differed from the profiles of *in-vitro* aged oocytes, which were characterized by a pronounced diminished metabolic activity. While in the fresh group, 67% of the oocytes developed into expanded blastocysts, none of the *in-vitro* aged oocytes with low metabolism produced a blastocyst ($p < 1x10^{-05}$). Interestingly, MST oocytes that were imaged 1h after nuclear reconstruction, showed a restored metabolic spectrum that resembled the profile from fresh non-manipulated controls. This restoration of the metabolic activity was concomitantly associated with an enhancement of developmental competence, with expanded blastocyst rates (63%) comparable to those of fresh non-manipulated controls ($p = 0.668$). Blastocyst developmental rates of fresh oocytes after hyperspectral imaging were comparable to oocytes from the same cohort that were not imaged and used as controls.

Limitations, reasons for caution: The metabolic profiles obtained from these experimental groups need to be correlated with implantation rates in mouse. The impaired embryo developmental pattern characteristic of poor-quality oocytes may not be exclusively attributed to metabolic deficiencies, so caution must be exerted when generalizing these results to oocytes with other cytoplasmic dysfunctions.

Wider implications of the findings: MST experiments confirm that the developmental decline of these oocytes is primarily attributed to abnormal function of cytoplasmic factors involved in metabolism, while the nuclear genome remains developmentally competent. MST can benefit from

hyperspectral imaging to identify oocytes with impaired developmental potential within a cohort.

O-209 The incidence of different ploidy alterations in abnormally fertilized oocytes (AFO)-derived embryos

L. Girardi[1], F. Cogo[1], P. Zambon[1], I. Pergher[1], J.A. Castellòn[2], C. Patassini[1], C. Rubio[3]

[1]*Igenomix Italy, Reproductive genetics, Marostica, Italy*
[2]*Igenomix Spain, Research and Development, Paterna, Spain*
[3]*Igenomix Spain, Reproductive genetics, Paterna, Spain*

Study question: Which is the incidence of *de novo* ploidy alterations in different abnormally fertilized embryos categories analysed with SNP-array?

Summary answer: Based on the number of pronuclei (PN) identified, 0PN embryos were mostly diploid, while 1PN and >2PN-derived embryos showed increased rates of ploidy abnormalities.

What is known already: Recent development of SNP-array and haplotyping by sequencing approaches are contributing to expanding preimplantation genetic testing (PGT) clinical utility including ploidy level evaluation. When applied to euploid embryos derived from AFO, the identification of abnormal ploidy constitution (i.e., haploidy, triploidy, or tetraploidy) could rescue viable diploid embryos otherwise considered non-transferable in IVF. However, no definitive genetic evidence has been obtained showing the incidence of different ploidy abnormalities in each AFO-derived blastocyst category. Here we present 4 years of experience in the clinical application of a validated SNP-array based protocol and custom-made algorithm to detect ploidy defects in AFO-derived embryos.

Study design, size, duration: Prospective observational study evaluating the incidence of altered ploidy configurations in AFO-derived blastocyst. After PN check, AFO samples were divided as follow: absence of observed pronuclei (0PN), monopronuclear (1PN), more than two pronuclei observed (2.1PN, with one smaller additional PN and 3PN). Genetic classification combining PGT-A and ploidy analysis was performed at Igenomix Italy laboratory between May 2019 and January 2023 on 133 AFO-derived embryos (44 0PN, 59 1PN, 30 >2PN).

Participants/materials, setting, methods: Multi-centre study involving 293 consenting patients of advance maternal age (mean=38.6 ± 3.9) undergoing PGT-A on MDA-WGA using Ion ReproSeq kit and IonTorrent S5 (ThermoFisher). SNP-array-based ploidy test was performed using HumanKaryomap-12 kit and NextSeq550 (Illumina). Proprietary algorithm was based on genome-wide BAF obtained: expected BAFs were 1, 0.5 or 0 for diploids,1 or 0 for haploid and 1, 0.66, 0.33 or 0 for triploids, as determined by the frequency of each allele for 300000 SNPs loci.

Main results and the role of chance: Preclinical validation of SNP-array-based ploidy test included 26 samples with known ploidy status and karyotype: 7 triploid re-biopsies, 7 haploid left-overs and 12 cell lines. Moreover, inter-platform comparison of 72 diploids, 9 triploids, 8 haploids embryos analysed with an alternative targeted-NGS approach, validated by Igenomix, showed 100% (95% CI= 95.94%-100%) concordance. In this study, a total of 318 AFO-derived embryos were collected for PGT-A analysis for different indications. Of these, 58.2% (n = 185/318; 95%CI=52.54-63.66) resulted as aneuploid. The remaining 133 euploid AFO-derived blastocyst where subjected to SNP-array based ploidy assessment. 0PN-derived blastocysts (n = 44/133) were diploid in 93.2% (n = 41/44; 95%CI=81.34-98.57) of cases; only 4.5% (n = 2/44; 95%CI=0.56-15.47) were haploid and 2.3% (n = 1/44; 95%CI=0.06-12.02) were polyploid. 1PN-derived blastocysts showed all possible ploidy configurations in these proportions: 59.3% (n = 35/59; 95%CI=45.74-71.93) haploid, 35.6% (n = 21/59; 95%CI=23.55-49.13) diploid and 5.1% (n = 3/59; 95%CI=1.06-14.15) polyploid. Finally, in the group of AFO where more than 2PN were observed (2.1PN or 3PN), the additional PN resulted in 66.7% (n = 20/30; 95%CI=47.19-82.71) of polyploid configurations, the remaining 33.3% (n = 10/30; 95%CI=17.29-52.81) were diploid. No haploid results were obtained from this category. Chi-square test showed significant overall correlation between PN category and ploidy status configurations ($p < 0.05$). Collectively, ploidy evaluation of 133 AFO-derived embryos, allowed the clinical use of 72 additional euploid/diploid embryos otherwise not considered for transfer.

Limitations, reasons for caution: Ploidy assessment protocol was not tested to distinguish triploids from tetraploids. Parental origin of each chromosomal set could not be determined without analysing parental DNA. The way of performing PN check could have affected AFO classification. In future studies we will focus on evaluating clinical outcomes following euploid/diploid embryo transfer.

Wider implications of the findings: An altered number of pronuclei is predictive of the correspondent altered ploidy status, while 0PN category doesn't represent a clear indication for ploidy evaluation. Nevertheless, a significant proportion of euploid/diploid embryos can be rescued from all types of AFO, potentially increasing the overall chance to achieve a live birth.

O-210 Detection of small copy number variations as incidental findings in PGT-A: clinical utility from a multisite experience including 12,157 patients

A. Iturriaga[1], L. Picchetta[2], C. Vega[1], M. Figliuzzi[2], M. Poli[2], C. Whitehead[3], A. Capalbo[2], X. Tao[1], V. Jobanputra[1], N. Loia[1], C. Jalas[1]

[1]*Juno Genetics- US, Genetic Lab, Basking Ridge, U.S.A.*
[2]*Juno Genetics- Italy, Genetic Lab, Rome, Italy*
[3]*IVIRMA, Clinical Research, Basking Ridge, U.S.A.*

Study question: What is the technical accuracy and clinical utility of reporting small copy number variants (CNVs below 3Mb) detected by a targeted next-generation sequencing-based PGT-A platform?

Summary answer: Some pathogenic or likely pathogenic CNVs <3Mb can be accurately detected by this assay, increasing clinical utility of PGT-A for a subset of IVF patients.

What is known already: CNVs are linked to a wide range of phenotypes, spanning from syndromes that include reduced penetrance and variable expressivity to more severe phenotypes. Prenatally, the prevalence of pathogenic CNVs is approximately 1.5%. Most PGT-A platforms that rely on whole genome amplification and shallow sequencing have a resolution limit of 5-10 Mb, preventing the detection of smaller CNVs. Here, we report an innovative PGT-A assay that interrogates thousands of targeted sites in the genome to provide robust copy number analysis allowing for the identification of some small CNVs (incidental findings, IF), outside the primary scope of detecting whole-chromosome aneuploidies in PGT-A.

Study design, size, duration: Retrospective observational study performed between 2020-2022, involving 12,157 patients who underwent PGT-A performed by targeted-NGS (PGTseq-A) for whole chromosome and large segmental aneuploidies. If an IF < 3 Mb was detected in multiple embryos, the couple was advised to undergo follow-up analysis by chromosomal microarray (CMA) to confirm the parental origin of the CNV, define its breakpoints and determine whether it is classified as benign-likely benign (B/LB), variant of uncertain significance (VUS) or pathogenic-likely pathogenic (P/LP).

Participants/materials, setting, methods: The PGTseq-A assay employed amplifies 5,000 amplicons across the genome to evaluate copy number. Validation was performed using 5-cell samples from cell lines with known CNVs, and trophectoderm biopsies from embryos with known parental structural rearrangements. An IF was reported when a gain/loss of at least

three consecutive amplicons appeared in at least two embryos from the same cycle. Transfer data was reviewed to determine which embryos were transferred. This study received IRB approval.

Main results and the role of chance: In 77 out of 12,157 PGT-A patients (0.63%;95%CI:0.5-0.8%), an IF that met reporting criteria was identified. To determine the size and pathogenicity, a CMA follow up was requested and performed on 67 couples. In all cases, one of the partners was confirmed to have the CNV identified in the embryos (100.0%: N 67/67 95%CI:94.6-100). The identified CNV was of maternal origin in 36 cases (53.7%) and of paternal origin in 31 cases (46.2%). A strong correlation was identified between PGT-A-predicted CNVs and the genomic coordinates defined by the CMA on parental DNA ($r = 0.86$). All CNVs intervals predicted by the PGT-A included the CMA genomic region. Twenty-seven (40.2%) were classified as B/LB, 31 (46.2%) as a VUS, and 9 (13.4%) as P/LP. Six of the nine P/LP cases (66.6%) involved imbalances of 16p. The remaining P/LP cases involved deletions of X, 15q and 18p11.32. From a review of transfer data, patients typically transferred embryos negative for IFs as first option regardless of the morphology and pathogenicity classification of CNV-positive sibling embryos. Specifically, in 8 cycles where a detected CNV was classified as B, LB or as VUS, negative embryos were prioritized for transfer despite their poorer morphology.

Limitations, reasons for caution: De novo CNVs were not considered by design because the reported CNVs had to be present in at least two embryos from the same cohort. Furthermore, the detection of small CNVs is not uniform in the genome and the negative predictive value of the assay for non-targeted regions is null.

Wider implications of the findings: This PGT-A assay accurately detects small pathogenic CNVs without prior knowledge of parental inheritance, enhancing clinical utility in a subset of patients. Additionally, reporting of VUS and B/LB findings may impact couples' decision-making concerning embryo selection, reinforcing that scientific rigor is a necessity when evaluating the capabilities of PGT-A.

O-211 A comparative analysis of non-invasive preimplantation genetic testing for aneuploidies using next-generation sequencing on day 5 and day 6 spent culture media versus trophectoderm

A. Strychalska[1], W. Sierka[2], A. Kokot[1], N. Jodlowec-Lubanska[1], U. Wroblewska[2], P. Mermer[2], K. Simka-Lampa[1], E. Morawiec[1,3], A. Pudelko[1,4], A. Bednarska-Czerwinska[1]

[1]Gyncentrum Sp. z o. o., Genetic Laboratory, Sosnowiec, Poland
[2]Gyncentrum Sp. z o. o., Embryology, Katowice, Poland
[3]University of Technology, Faculty of Medicine, Katowice, Poland
[4]Medical university of Silesia, Clinical Biochemistry, Sosnowiec, Poland

Study question: Purpose of this study was to analyze concordances between trophectoderm and spent culture medium from different embryo culture length (day 5 and day 6).

Summary answer: Material collected from embryos cultured to day 6 are more suitable for non-invasive preimplantation genetic testing for aneuploidies.

What is known already: Ni-PGTA (Non-invasive Preimplantation Genetic Testing for Aneuploidy) is a relatively new testing method that analyzes spent culture medium from in vitro fertilization (IVF) embryos to determine the genetic makeup of the embryos. This non-invasive approach eliminates the need for biopsy and allows for the identification of chromosomal abnormalities such as aneuploidy. The utility of ni-PGTA is to provide an efficient, accurate, and safe method for preimplantation genetic screening. The concordance between ni-PGTA and traditional biopsy-based methods for detecting aneuploidy is high, but still further research is needed to fully evaluate its accuracy and reliability.

Study design, size, duration: The study was conducted in 2021-2022 and approved by the Institution of the Bioethical Committee operating at the Regional Medical Chamber in Krakow (No. 161/KBL/OIL/2021). Informed consent for participation in the study was obtained from all patients. A total of 130 embryos were obtained: 70 from 15 patients after 5 days of culture and 60 from 11 patients after 6 days of culture.

Participants/materials, setting, methods: Whole genome amplification of collected materials was conducted using the SurePlex Kit (Illumina, San Diego, CA, USA). The libraries was prepared using VeriSeq PGS (Illumina, San Diego, CA, USA) according to manufacturer protocol. Sequential analysis was then performed on the miSeq device (Illumina, San Diego, CA, USA). The efficiency of WGA, the concordance of chromosome status between biopsied cells and media were investigated.

Main results and the role of chance: The mean DNA concentration of WGA products from embryos for day 5 from TE was 29,6 ± 2,7 (ng/µl ± SD) for SCM 23,4 ± 4,2 (ng/µl ± SD) and for day 6 from TE was 29,5 ± 2,7 (ng/µl ± SD) for SCM 33,4 ± 6,1 (ng/µl ± SD). The mean DNA concentration of TE between day 5 and day 6 are comparable but the comparison between SCM from day 5 and 6 shows significant difference. 5 of 60 samples considered uninformative based on a Derivative Log Ratio (DLR) - DLR >0.4 (TE day 6: 1 sample and SCM day 6: 4 samples) were excluded from the analysis. All samples form day 5 were informative. The overall concordance rate between the ni-PGTA for day 5 and PGTA was 39/70 (55,7%) and ni-PGTA for day 6 and PGTA was 52/55 (94,5%). Sex chromosome consistence between the ni-PGTA for day 5 and PGTA was 54/70 (55,7%) and ni-PGTA for day 6 and PGTA was 51/55 (92,7%)

Limitations, reasons for caution: Special care was taken while washing embryo before changing culture medium in order to avoid maternal contamination. Special precautions were taken to avoid losing genetic material between consecutive washing steps of TE. When Conducting ni-PGTA analysis, maternal contamination needs to be considered and results interpreted with caution.

Wider implications of the findings: The results of invasive PGT-A using TE are similar to the non-invasive method based on SCM. In addition, the best results were recorded for SCM cultured up to day 6. These results are another piece of evidence confirming utility of SCM analysis for the purpose of aneuploidy evaluation.

O-212 Screening IVF embryos with polygenic risk scores: risk reduction estimates, population impact, and attitudes of patients and clinicians

S. Carmi[1], D. Barlevy[2], L. Klausner[1], R. Furer[3], K.M. Kostick-Quenet[2], M. Mukherjee[4], I. Cenolli[3], T. Lencz[5], G. Lázaro-Muñoz[3], S. Pereira[2]

[1]The Hebrew University of Jerusalem, Public Health, Jerusalem, Israel
[2]Baylor College of Medicine, Center for Medical Ethics and Health Policy, Houston-TX, U.S.A.
[3]Harvard Medical School, Center for Bioethics, Boston- MA, U.S.A.
[4]University of California- Berkeley, Sociology, Berkeley- CA, U.S.A.
[5]Zucker School of Medicine at Hofstra/Northwell, Psychiatry and Molecular Medicine, Hempstead- NY, U.S.A.

Study question: IVF embryos can now be screened for complex diseases. What is the expected risk reduction? What are the attitudes of patients and clinicians?

Summary answer: Substantial risk reductions can be achieved, but only in the best-case scenario. The views of patients and clinicians regarding the technology are not fully aligned.

What is known already: It recently became possible to screen IVF embryos for a variety of complex diseases using polygenic risk scores. Prioritization of embryos for transfer based on these scores may lead to reduced disease risk in offspring. Preliminary risk reduction modeling suggested that substantial risk reductions are possible, particularly when screening for a single disease. However, multiple factors remain unexplored, such as the effect of implantation failure and assortative mating on risk estimates and the impact of embryo

prioritization on population allele frequencies. The attitudes of IVF patients and clinicians towards polygenic embryo screening are also unknown.

Study design, size, duration: We estimated the expected risk reduction under various settings using statistical modeling, based on the liability threshold model and other quantitative and population genetic models.

To learn about attitudes of patients and clinicians, we performed in-depth, semi-structured interviews with 26 USA patients and 27 USA clinicians over a period of about one year.

Participants/materials, setting, methods: We used R to numerically estimate risk reductions and implemented a web app in Shiny.

To recruit patients and clinicians for the interviews, we used flyers (for patients), emails on publicly available lists (for clinicians), snowball sampling, and convenience sampling. Interviews were conducted over Zoom for one hour each by a single interviewer (D.B.). The study was approved by Baylor College of Medicine's IRB committee. We applied deductive and inductive thematic analysis using a team-based approach.

Main results and the role of chance: Statistical genetic modeling suggested that with five viable embryos, risk reductions of up to 50% can be achieved when screening for a single common disease. We developed a risk reduction estimator web app, allowing users to examine the effect of the number of embryos, the accuracy of the score, the selection strategy, and the score percentile or disease status of the parents. Assortative mating and modeling of implantation failures are expected to only slightly decrease risk reductions. Risk allele frequencies are expected to change very little across generations even if embryo selection becomes widespread.

In interviews, patients accepted screening for health conditions, particularly severe diseases. Many were concerned about costs, and some were interested in screening for informative purposes. Most patients did not oppose screening for traits. In contrast, about half of clinicians were unwilling to offer screening due to concerns over utility, implementation, harm to patients, and lack of scientific validity, although all were willing to reconsider it in the future for specific conditions. Many clinicians considered screening for traits a non-medical procedure. About half agreed that screening should be regulated.

Limitations, reasons for caution: The risk reduction estimates may depend on the assumptions of the statistical models. As with any qualitative research, interview findings may not be generalizable. Furthermore, the design of the semi-structured interview guide may have influenced participants' expressed attitudes.

Wider implications of the findings: In the best-case scenario, prioritizing IVF embryos based on polygenic scores may achieve substantial risk reductions. Several initial concerns seem unfounded. IVF patients are broadly interested in the technology but may be unaware of its many limitations. Clinicians have major concerns regarding clinical implementation and harm to patients.

O-213 Breathing New Life into Air Pollution Research: Examining the Link Between Air Pollution and Adverse Birth Outcomes in the Eastern Mediterranean Region (EMR)

E. Whaibeh[1,2], G. Abi Tayeh[3], W. Farah[4], M. Abboud[4], M. Mrad Nakhlé[1]

[1]*University of Balamand UOB, Public Health Department, Beirut, Lebanon*
[2]*Université Saint-Joseph de Beyrouth USJ, Doctoral School of Health and Sciences-Faculty of Medicine, Beirut, Lebanon*
[3]*Université Saint-Joseph de Beyrouth USJ, Faculty of Medicine, Beirut, Lebanon*
[4]*Université Saint-Joseph de Beyrouth USJ, UEGP – Environmental- Genomic and Proteomic Research Unit- Faculty of Sciences, Beirut, Lebanon*

Study question: What is the current understanding of the relationship between air pollution and perinatal health in the EMR?

Summary answer: The literature on exposure to air pollutants and perinatal health in the EMR is scarce, limited in scope, and using simply study designs and methods.

What is known already: Air pollution is a significant public health concern in the Eastern Mediterranean Region, due to many factors such as the arid nature of the region, rapid urbanization, oil production, and the emissions from the transportation, energy productions, and other practices. Not only can the degradation in air quality put the health of infants in jeopardy but it can also increase the risk of adverse pregnancy outcomes. Studies on air pollution and birth outcomes and early life development have been conducted in other parts of the world, but only a small number have been conducted in the EMR.

Study design, size, duration: The authors conducted a comprehensive search of various databases to identify relevant studies and publications on the topic. The findings were then critically evaluated and discussed in relation to the current understanding of the relationship between air pollution and perinatal health in the EMR. The study does not include any new data collection or primary research. The authors used a narrative approach to synthesize the existing literature on the topic.

Participants/materials, setting, methods: Not applicable

Main results and the role of chance: The existing literature is concentrated in specific geographic locations out of the 22 countries and territories that comprise the region, and it is focused on a limited number of exposures and outcomes, namely secondhand smoking and criteria air pollutants. The main gaps include the inconsistent and poorly funded air quality monitoring, inappropriate study designs, imprecise and/or unreliable assessments of exposures and outcomes, and the focus on traditional air pollutants rather than new emerging and increasingly concerning air pollutants. Moreover, even though the studies establish associations between air pollutants and adverse birth outcomes, the mechanisms through which these processes take place are yet to be fully understood. An area of research that holds great potential in explaining these processes is epigenetics; however, due to limited funding, expertise and health and environmental data, epigenetic research on the impact of air pollution in the EMR is still in its infancy.

Limitations, reasons for caution: The review is based on a narrative approach, which is subjective and may not be as rigorous as a systematic review. The reviewed studies also have their own limitations, such as inconsistent air quality monitoring and imprecise assessments of exposures and outcomes. Studies focused on epigenetics in EMR are scarce.

Wider implications of the findings: The review highlights the need for future research examining the epigenetic processes that underlie the adverse birth outcomes, to better understand them and to develop effective recommendations and intervention strategies.

Trial registration number: Not applicable

O-214 interaction of air pollution and meteorological factors on IVF outcomes: a multicenter study in China

S. Wu[1], J. Tan[1], Y. Zhang[2], G. Hao[3], X. Chen[4], X. Wu[5], R. Haiqin[6]

[1]*Shengjing Hospital of China Medical University, Centre of Reproductive Medicine, Shenyang, China*
[2]*Tianjin Central Hospital of Obstetrics and Gynecology, Obstetrics and Gynecology, Tianjin, China*
[3]*The Second Hospital of Hebei Medical University, Department of Reproductive Medicine, Shijiazhuang, China*
[4]*The Affiliated Hospital of Inner Mongolia Medical University, Reproductive Medicine Centre, Hohhot, China*
[5]*Shanxi Women and Children's Hospital, Gynecology and Obstetrics Center, Taiyuan, China*
[6]*Jinghua Hospital, none, Shenyang, China*

Study question: Is there an interaction between air pollution and meteorological factors on IVF outcomes?

Summary answer: The correlation between air-pollutant exposure and IVF outcomes was modified by meteorological conditions, especially temperature and wind speed.

What is known already: Previous studies revealed associations between air-pollutant exposure and *in vitro* fertilization (IVF) outcomes. However, modification effects of air pollution on IVF outcomes by meteorological conditions remain elusive.

Study design, size, duration: Multicenter retrospective cohort study, 2015–2020.

Participants/materials, setting, methods: This multicenter retrospective cohort study included 15,217 women from five northern Chinese cities during 2015–2020. Daily average concentrations of air pollutants ($PM_{2.5}$, PM_{10}, O_3, NO_2, SO_2, and CO) and meteorological factors (temperature, relative humidity, wind speed, and sunshine duration) during different exposure windows were calculated as individual approximate exposure. Generalized estimating equations and stratification models were used to assess the associations of air pollution and meteorological conditions with IVF outcomes and estimated potential interactions.

Main results and the role of chance: Exposure to $PM_{2.5}$, SO_2, and O_3 was adversely correlated with pregnancy outcomes in fresh IVF cycles. Positive associations of wind speed and sunshine duration with pregnancy outcomes were detected. In addition, we observed that embryo transfer in spring and summer had a higher likelihood to achieve a live birth compared with winter. In stratified models, pieces of evidence of interaction between meteorological factors and air pollutants on pregnancy outcomes were detected. Negative associations of $PM_{2.5}$ with clinical pregnancy were only significant at lower temperatures and wind speeds. Moreover, the effects of O_3 on live birth were enhanced by higher quartiles of wind speed.

Limitations, reasons for caution: First of all, we used the data from monitoring stations to estimate the individual exposure, which was inaccurate and may introduce bias. Second, due to data limitations, this study did not discuss socio-economic factors, which were reported to be associated with spatial-temporal variations of air pollutants and reproductive outcomes.

Wider implications of the findings: Pregnant women should be advised to reduce outdoor time when the air quality was poor, particularly at lower temperatures.

Trial registration number: not applicable

O-215 Negative impact of the reduction in family income following the SARS CoV 2 Covid 19 pandemic on access to Assisted Procreation : observational study

A. Pacchiarotti[1]

[1]*San Filippo Neri Hospital, IVF Unit, ROMA, Italy*

Study question: What are the consequences of the health emergency and the consequent restrictive measures on the economic accessibility of medically assisted procreation techniques.

Summary answer: Reduction of family income rate and consequentely bias of PMA attempts rate

What is known already: - The birth rate in Italy over the past 10 years has been declining rapidly and continuously

- Fertility income correlation has an inversely proportional trend demonstrated in a study conducted by the Ministry of Economy and Finance and Istat

- Pandemic has further impoverished Italian families

Study design, size, duration: This is a transversal observational study conducted at the Assisted PReproduction Center of the San Filippo Neri hospital in Rome between Jenuary 2021 and December 2022

The results were obtained by administering an online questionnaire consisting of 20 multiple choice questions to which the participants answered anonymously.

Participants/materials, setting, methods: Two hundred and ninety-five patients were enrolled with an overall average age of 37.5 years (minimum age 25, maximum age 47).

Main outcomes measures. Bias of PMA attempts rate. Reduction of family income rate

Main results and the role of chance: Majority of people said they have not seen their desire for offspring reduced since the onset of health emergency. the willingness to use MAP techniques during the pandemic remained unchanged for 58.7% of respondents, increased for 12.5% and decreased for the remaining 28.8%. The individuals who have declared to have momentarily renounced to the procedures of PMA have been 31.7%, of these 24% has renounced because of economic factors. When asked about the cost of the necessary medical procedures, 62.5% of the participants considered the price in public facilities to be "adequate" and 79.8% defined the cost in private clinics as "excessive".

Limitations, reasons for caution: A limitation of the study may be the comprehension of the questionnaire, since it could not be speieged verbally. The administration was done online, so there is no assurance that it was received by everyone. Therefore, the percentage of patients who did not respond may be overestimated

Wider implications of the findings: The study and analysis of these data provides a current overview of the condition of infertile couples in our country, so that all useful interventions can be put in place to restore the interest and economic conditions necessary for the initiation of medically assisted procreation.

Trial registration number: not applicable

Abstract citation ID: dead093.262
O-216 Sex, smoking, age and natural fecundity: results of a survey performed on 2510 puerperal women and their partners

M.I. Limia Pérez[1], **R. Matorras Weining**[1]

[1]*Cruces University Hospital, Gynecology and Obstetrics, Barakaldo, Spain*

Study question: Sex, smoking, age and natural fecundity: results of a survey performed on 2510 puerperal women and their partners.

Summary answer: We reported that the best fertility marker was amongst couples who had 7 intercourses per week.

What is known already: Most reproductive scientific societies recommend that infertility studies begin after 12 months of unprotected intercourse without pregnancy. There is a series of parameters whose influence on assisted reproduction has been extensively studied, but which have received little attention when studying natural fertility. For example, it is well known that human fertility is strongly related to female age and that there is a decline in ART success rates with increasing woman's age. Also smoking has been reported to decrease fertility in women, both in natural fertility and in ART cycles.

Study design, size, duration: The aim of our study was:

1) to analyze the cumulative fecundity rate (CFR), the per month fecundity rate (FR) and the time to pregnancy (TTP).

2) to ascertain the influence of woman and male age, smoking, previous fertility and frequency of sexual intercourse in the aforementioned fecundity markers.

Participants/materials, setting, methods: The study population consisted of 2510 puerperal women and their partners whose labor was performed at our Hospital. During a 12-month period, an anonymous survey was performed during hospital admission, within 36-72 hours postpartum. The survey was offered to all postpartum women, although only those who met the inclusion criteria were analyzed.

Main results and the role of chance: - There was a close correlation between woman's age and male's age (Pearson coefficient= 0.72, $p < 0.00001$). When the age of one partner was considered independently of the age of the other there was no correlation between woman's age and TTP (Person coefficient = 0.04, $p = 0.08$) or between man's age and TTP (Person coefficient = 0.02, $p = 0.38$).

- There was a significant correlation between TTP (time to pregnancy) and man's age (Pearson coefficient= 0.07, p = 0.0006).
- We observed a significantly higher fecundity rate (FR) at the first month and a significantly higher cumulative fecundity rate (CFR) at 3 and 6 months in non smokers. Moreover we found a significant correlation with the number of cigarettes smoked and the TTP. It has to be highlighted that in our study the fertility impact of smoking was remarkably higher in men than in women.
- Pregnancy rates were similar, independently the existence or not of previous pregnancies.
- Regardless of coital frequency and natural fertility, our study revelaed two remarkable facts, one related with infrequent intercourse and the other regarding frequent. The best fertility marker among the couples was reported a 7 per week coital frequency.

Limitations, reasons for caution: - Only couples reaching pregnancy were studied.
- Second hand smoking was not considered.
- Possible inaccuracy because at long-term recall, TTP may sometimes only be estimated roughly by couples completing the questionnaire.
- Assumption that it is only one cycle per month.
- Misscariages were not taken into account.

Wider implications of the findings: Our results challenge the widely accepted idea that among healthy women trying to conceive, nearly all pregnancies can be attributed to intercourse during a 6-day period ending on the day of ovulation. We reported that the best fertility marker was amongst couples who had 7 intercourses per week.

SESSION 69: REGULATION, INNOVATION, AND MORAL RESPONSIBILITY IN MEDICALLY ASSISTED REPRODUCTION

Tuesday 27 June 2023 Auditorium 10-12 17:00 - 18:00

Abstract citation ID: dead093.263
O-217 Balancing 'the desires of individuals' against 'the situation of the world as a whole': (Re)considering planetary responsibilities in the context of assisted reproduction

S. Segers[1]

[1]*Maastricht University, Department of Health- Ethics and Society, Maastricht, The Netherlands*

Study question: How do the moral reasons for offering access to assisted reproductive technology (ART) relate to ethical responsibilities generated by sustainability and planetary health duties?

Summary answer: If one accepts that both governments and medical professionals should yield to environmental sustainability, it is ethically pertinent to balance this against respecting reproductive autonomy.

What is known already: Respecting autonomy is a central ethical value in the context of reproduction, which, in the context of ART, is considered to generate a prima facie obligation to help people conceive a child in line with their personal goals. Arguments in terms of population ethics, use of planetary resources and climate change are traditionally not considered to counter arguments for access to ART relying on the reproductive autonomy of individuals. This may come under tension due to adjusted encouragements to physicians for being committed to sustainability as part of professional role responsibilities.

Study design, size, duration: A literature study of academic literature and institutional codes of conduct was performed to inventory how professional duties of physicians are being directed to encompass not only responsibilities towards individual patients, but also towards environmental sustainability. Consideration of earlier documents has shown that, sporadic objections notwithstanding, such arguments have mostly been morally inconsequential in the regulation and praxis of ART. This was critically evaluated against the backdrop of bioethical literature and ethical principles.

Participants/materials, setting, methods: Literature study; conceptual analysis; normative analysis.

Main results and the role of chance: Climate change and its future impact is on the political agenda as a shared responsibility of governments, industry, and citizens. This is seeping through into communiqués of professional medical bodies and codes of conduct. In the particular context of ART, this has recently led to several calls to recognize the impact of climate change on fertility. This has not (yet) led to an institutionalization of the more provocative claim, sometimes voiced in popular media, that fighting climate change may require restraints in the area of procreation. Nonetheless, claims that physicians have a responsibility to contribute to a sustainable healthcare sector at least require ethical attention in this regard, especially in view of observed shifts compared to canonic positions. Likewise, if we expect governments to take efforts to attain sustainability goals, this may evoke moral questions about possible tensions with moral commitments to offering access to assisted procreation. This contribution addresses (i) the limited critical stance towards beliefs that procreation is problematic from a planetary health perspective, and (ii) the need to scrutinize the ethical balance for reproductive health professionals between accommodating (individual) procreative goals and more global responsibilities towards the world at large.

Limitations, reasons for caution: This is an agenda-setting analysis, and so it is not meant to serve as an exhaustive discussion of these moral concerns. While attention for future impacts of climate change is gaining momentum in healthcare, controversial suggestions to cap procreation is largely still limited to lay contexts.

Wider implications of the findings: This analysis is meant to propel ethical reflection about the balance between global elements that may restrain individuals' reproductive options. This puts into focus that moral considerations about individual and societal (and planetary) interests in the context of ART require continued specification and careful ethical deliberation.

Trial registration number: n/a

O-218 A quantitative investigation into UK public attitudes towards embryo research and the 14-day rule

S. Norcross[1]

[1]*Progress Educational Trust, Director, London, United Kingdom*

Study question: Is there UK public acceptance for increased embryo research and the extension of the 14-day rule?

Summary answer: Respondents broadly supported the use of human embryos in research but believed the 14-day-rule remains 'about right'. However, this might be extended under certain circumstances.

What is known already: UK's Human Fertilisation and Embryology Act (1990 as amended) may be reviewed in the near future. The Act currently allows licensed research on embryos up to the equivalent of the 14th day of development. The former PET Patron, the late Baroness Mary Warnock, was largely responsible for establishing the 14-day rule in UK law. The rule was subsequently adopted by many countries and institutions around the world. Baroness Warnock's work on this issue gave confidence to scientists and the wider public alike.

Study design, size, duration: This is a quantitative piece of research commissioned by PET. The field work was carried out by Ipsos who interviewed a sample of 2,233 adults aged 16-75 in UK using its online i:omnibus. The responses were gathered between 24 and 27 March 2022. The data has been weighted to the known offline population proportions for age, working status and social grade within gender and Government office region.

Participants/materials, setting, methods: The principal material used was an online questionnaire developed by PET and its advisers with the input of Ipsos survey research experts. All research was carried out in accordance

with the requirements of the international quality standard for market research, ISO 20252, and in accordance with the Ipsos Terms and Conditions. All percentage calculations are rounded up to the nearest whole number. Where percentages do not add up to 100%, this is due to rounding.

Main results and the role of chance: =Only 11% of respondents could give a scientifically correct definition of a human embryo.

=More than 40% of those surveyed said they supported the use of human embryos in scientific and medical research.

=44% supported the government funding of such research with 17% being opposed.

=Asked whether the 14-day limit is too long, too short or about right, more than half of those who supported (or neither opposed nor supported) the use of laboratory-created human embryos in research responded that the limit was about right.

=Those not implacably opposed to embryo research were willing to countenance an extension to the '14- day rule', if reasons were presented to them.

=This demonstrates the importance of scientists giving a clear explanation of the benefits that such an extension to the 14-day rule may bring.

=The most supported reasons for an extension were to find new treatments for congenital diseases, improving medical understanding of stillbirth and miscarriage.

=However, with significant numbers remaining neutral or answering, 'Don't know', this situation could change. Public education is vital to help people engage.

=The sample size of 2233 people allowed for statistically significant differences to be identified and reduced the risk of misleading answers.

Limitations, reasons for caution: This research is a snapshot in time and public opinion can evolve with new information. A significant number of respondents gave a 'don't know' answers. If these members of the public were to shift their view to either 'support or opposition' then the landscape for embryo research could markedly alter.

Wider implications of the findings: The study suggests there is limited public understanding of this subject, as illustrated by only 11% of respondents selected the scientifically correct definition of an embryo. This gap in knowledge makes it challenging to have a meaningful national debate on the potential changes to the current law.

Trial registration number: Trial registration number is not applicable. PET are grateful for the generous support of Ferring without which it would not have been possible to conduct this piece of wide-ranging, nationally representative research.

Abstract citation ID: dead093.265
O-219 Surplus Frozen Eggs Lay to Waste Opportunities for Research and Treatment

G. Fuscaldo[1], M. Johnston1[1], S. Hunt[2], C. Mills[1], L. Rombauts[2]

[1]*Monash University, Monash Bioethics Centre, Clayton, Australia*
[2]*Monash University and Monash IVF, Monash Bioethics Centre- Department of Obstetrics & Gynaecology and Monash IVF, Clayton, Australia*

Study question: Is there a moral duty to donate surplus frozen eggs (SFEs)?

Summary answer: SFEs are a valuable resource with the potential to mitigate harm and improve well-being and should be donated where the costs to donors are small.

What is known already: In Victoria, Australia, eggs can be stored for up to 10 years, after which SFEs must be discarded, donated to research or to others. Our research shows that many people do not return to use their frozen eggs, many are left in storage and most SFEs are then discarded. At the same time, there is a serious shortage of donated gametes and a high demand for eggs for both research and reproductive treatments. The recent legalisation of mitochondrial donation in Australia has added to the demand for eggs for training, research, and clinical purposes.

Study design, size, duration: This paper considers whether donation of SFEs can be grounded on 'the duty of easy rescue', broadly defined as a moral duty to help others when the harm that might be averted is sufficiently great, and the costs are sufficiently small.

Participants/materials, setting, methods: We present an ethical analysis of the harms that could be mitigated by egg donation and the costs to donors associated with donation to both research and to others.

Main results and the role of chance: The harms associated with prolonged infertility, long waiting lists for donor eggs, and gamete donation in less regulated settings are well known. In addition, the use of donated eggs for mitochondrial replacement offers the possibility of avoiding the transmission of serious disease. Our research shows that many SFEs are abandoned or discarded but little is known about why people discard SFEs. Among the 'costs' to donors, there are logistical barriers such as the time needed, and the physical and emotional demands associated with donor eligibility screening. There may be additional emotional and ethical costs associated with donation to others; concerns about donor anonymity, the parental status of donors, and the meaning of genetic relationships have been cited as barriers to embryo donation and may also factor in egg donation. We suggest that while donation of SFEs to others may have costs, there are opportunities to facilitate this option, such as offering donor screening at the time of egg freezing, providing education about the current demand for SFEs, and greater discussion and critical reflection about the moral status of donors. We reason that donating to research does not incur the same 'costs' and in most cases, represents an 'easy rescue'.

Limitations, reasons for caution: This analysis considers 'costs' to donors and 'harms' relating to the shortfall of donor eggs. However, donors and recipients are not the only actors involved in egg donation. There may be other morally relevant considerations, such as the experience of donor-conceived people, that complicate assessments of costs, harms, and benefits.

Wider implications of the findings: The large number of SFEs abandoned and discarded suggests the need for more serious consideration about the disposition of SFEs, prior to egg freezing. In addition, more information should be provided to would-be users about the current fate of and demand for eggs.

O-220 Artificial intelligence for embryo selection: ethical, social and regulatory issues

C. Mills[1], M. Johnston[1], J. Koplin[1]

[1]*Monash University, Monash Bioethics Centre, Clayton, Australia*

Study question: What are the key ethical, social and regulatory issues raised by artificial intelligence technologies (AI) for embryo selection, and how might these be best managed?

Summary answer: Key issues with AI for embryo selection include deskilling, transparency, accountability, and fairness. These require attention to improve psychosocial and clinical outcomes in ART.

What is known already: Artificial intelligence (AI) technologies play a growing role in the assisted reproductive technology (ART) sector. Machine learning holds enormous promise for improving the selection of human embryos for transfer after IVF. Time-lapse imaging in conjunction with machine learning has the potential to standardise and automate embryo selection, improving clinical outcomes. Promising results have recently been published, and AI tools have reached the market. However, ethical and regulatory analysis has not kept pace with the technology. There has been negligible research on the ethical, social, and regulatory issues raised by the use of machine learning methods for embryo selection.

Study design, size, duration: A terrain-mapping review of the academic literature was performed to identify the key social, ethical and regulatory issues raised by AI for embryo selection. This is part of a multi-method study, collecting qualitative and quantitative data alongside ethical and regulatory analysis.The study is expected to take 1 year.

Participants/materials, setting, methods: A systematic review of the extant literature on the ethical, social, and regulatory issues raised by machine learning for embryo selection, combined with a narrative review of the broader

literature on the use of AI in healthcare was undertaken. This review of ethical and regulatory issues will ultimately combine with data from semi-structured interviews and an online survey of ART patients and practitioners, including fertility specialists and embryologists, and ART regulators in Australia.

Main results and the role of chance: This paper reports on ethical and regulatory analysis of key issues that emerge from the use of AI for embryo selection. The use of AI in healthcare generally has raised serious concerns about deskilling and 'dehumanization'(as roles traditionally performed by humans are displaced by technology), transparency, accountability, and fairness. This paper examines these issues in the ART context, to begin to develop guidance on how to best implement this technology in ways that balances the interests of all stakeholders and is consistent with maintaining public trust in the field of ART.

Limitations, reasons for caution: It is anticipated that much of the analysis of the social, ethical and regulatory issues will be generalisable internationally. However, the study prioritises one context - that of Australia. Some features of the Australian context may limit generalisability.

Wider implications of the findings: There is a need to address the ethical, social and regulatory issues that arise with the emergence of innovative technologies within ART to maintain public trust and ensure that psychosocial and clinical outcomes are improved. Further data collection on stakeholder views of machine learning for embryo selection will be required.

O-221 Regenerative endometrial PRGF (plasma rich in growth factors) treatment in patients with thin endometrium, recurrent implantation failure, and recurrent miscarriages: a retrospective, self-controlled, cohort study

D. Bodri[1], S. Rogel[1], J.L. Abad[2], R. Paul[2], H. Izquierdo[1], J. Aizpurua[1]

[1]*IVF Life Alicante, Assisted Reproduction, Alicante, Spain*
[2]*IGLS, Reproductive Genetics and Immunology Laboratory, Alicante, Spain*

Study question: What reproductive outcomes are observed in patients submitted to endometrial PRGF therapy due to thin endometrium (ThE), recurrent implantation failure (RIF) and recurrent miscarriages (RM)?

Summary answer: Following endometrial PRGF treatment, success rates were significantly increased in ThE and RIF patients, whereas in the RM group pregnancy loss rates were not affected.

What is known already: Adequate development of a functional endometrium is a prerequisite for successful embryo implantation in ART cycles. In contrast, the management of patients with thin endometrial lining or recurrent implantation failure has been an ongoing challenge with none of the proposed surgical, hormonal, and pharmacological interventions achieving satisfactory results. In recent years, the use of plasma rich in growth factors (PRGF) - successfully applied in other medical fields - has become a novel treatment option in reproductive medicine. It was used experimentally both for ovarian follicle activation and to enhance endometrial receptivity although published studies are small with often contradictory results.

Study design, size, duration: All consecutive patients (n = 107) who underwent endometrial PRGF treatment (n = 150) in a single, private centre between 2016-2022 were included in this retrospective analysis. Patients were recruited into ThE (n = 64), RIF (n = 36) and RM (n = 7) groups, respectively. Live birth / ongoing pregnancy rates per embryo transfer were compared to success rates obtained in previous embryo transfers preceding the endometrial PRGF intervention. External Ethics Committee approval was obtained for a comparative pilot study including above patient groups.

Participants/materials, setting, methods: PRGF was obtained by processing the patients' autologous blood sample in an in-house validated open system. Endometrial PRGF interventions were performed using a thawed PRGF sample with a series of intrauterine instillations (43%) or with a combined approach performing hysteroscopic subendometrial infiltration during early follicular phase (57%). Endometrial preparation was conducted using an artificial hormone replacement protocol with high-dose oral estrogens and vaginal progesterone. Most embryo transfers involved the replacement of a single, vitrified-thawed blastocyst.

Main results and the role of chance: A total of 107 patients underwent 150 endometrial PRGF treatments and 131 subsequent embryo transfers. Altogether 19 (13%) embryo transfers were cancelled, higher in ThE than in the RIF group (16 vs 7.1%). In the ThE group (64 patients, 98 PRGF cycles and 107 controls), positive pregnancy (41 vs 32%, NS), clinical pregnancy (35 vs 22%, $p = 0.049$) and ongoing pregnancy/live birth rates (24 vs 4.7%, $p < 0.0001$) per embryo transfer were significantly higher in the endometrial PRGF treatment group compared to previous embryo transfers. In the RIF group (36 patients, 42 PRGF cycles and 101 controls), positive pregnancy (59 vs 20%, $p < 0.0001$), clinical pregnancy (44 vs 11%, $p < 0.0001$) and ongoing pregnancy/live birth rates (33 vs 7.9%, $p < 0.0001$) per embryo transfer were significantly higher in the endometrial PRGF treatment group compared to previous embryo transfers. In the RM group (7 patients, 10 PRGF cycles and 15 controls), positive pregnancy (50 vs 60%), clinical pregnancy (20 vs 27%) and ongoing pregnancy/live birth rates (0 vs 0%) per embryo transfer were not significantly different and no ongoing pregnancies were achieved. So far, 20 singletons and 1 set of twins have been confirmed to be born from the above PRGF cycles (12 pregnancies still ongoing).

Limitations, reasons for caution: Heterogeneity of clinical severity between included ThE patients could affect observed reproductive outcomes. The self-controlled design of the study might have influenced the comparison between pre-, and post-intervention pregnancy rates, although this also highlights the poor-prognostic nature of included participants. RM patients were too few to evaluate pregnancy loss rates.

Wider implications of the findings: This preliminary, retrospective study has shown that regenerative therapy using autologous PRGF is a safe, affordable, and efficient treatment option for ThE and RIF patients. Further randomized studies are warranted, although they are hampered by patient selection issues and the lack of applicable efficient treatment options in the non-intervention group.

Trial registration number: not applicable

Abstract citation ID: dead093.268

O-222 Functional characterization and clinical implications of patient-specific iPSC-derived endothelial cells to unravel the pathogenesis associated with androgen-mediated endothelial dysfunction in polycystic ovarian syndrome

C.C. Huang[1], M.J. Chen[1], J.H. Yang[1]

[1]*National Taiwan University Hospital, Obstetrics and Gynecology, Taipei City, Taiwan R.O.C.*

Study question: Whether and how the endothelial cell (EC) dysfunction is involved in the pathogenesis of PCOS revealed by iPSC-based disease modeling?

Summary answer: PCOS-specific iPSC-derived ECs were successfully established and the results showed that EC proliferation and function were impaired in PCOS through the androgen receptor(AR)-mediated signaling pathway.

What is known already: ECs have been shown to play critical biological roles in the regulation of vascular tone and inflammatory process and any injury to ECs or disturbance in their homeostasis is called EC dysfunction, which has been recognized as an early marker of atherosclerosis and cardiovascular diseases. Several studies have also revealed indirect evidence of EC dysfunction among women with PCOS, including elevated circulatory markers

of endothelial damage and impaired vascular structure. But whether and how EC dysfunction is involved in the pathogenesis of PCOS is still unclear.

Study design, size, duration: This is an experimental study at tertiary university hospital. iPSCs were established from skin fibroblasts and peripheral blood mononuclear cells from two patients with PCOS and two control participants.

Participants/materials, setting, methods: iPSCs were differentiated into ECs through monoculture with chemically defined conditions. Single cell RNA sequencing (scRNA-seq) was performed on the iPSCs-derived ECs to compare the differences between PCOS and control. iPSCs-derived ECs were treated with different dosages (1, 10 and 100 nM) of dihydrotestosterone (DHT). Cell cycle phases were analyzed by flow cytometry with BrdU incorporation assay. The expression of AR, cyclin-dependent kinase 1 (CDK1) and vascular endothelial growth factor (VEGF) were analyzed using rtPCR.

Main results and the role of chance: Up to 90% of iPSC-derived ECs successfully expressed EC markers, including CD31, CD144 and von Willebrand Factor in both PCOS and control groups, showing a high differentiation efficiency in the present study. The pathway enrichment analysis of transcriptomic data of iPSC-derived ECs showed functional differences involving cell cycle process, VEGF signaling and apoptotic process between PCOS and control. Analysis using sc-RNA seq revealed decreased cellular proliferation in the PCOS iPSC-derived ECs compared to control group, which was due to cell cycle arrest revealed by flow cytometry. The modulating effects of androgen on the proliferation and gene expression of iPSC-derived ECs were further investigated. DHT at doses ranging from 1 to 100 nM stimulated iPSC-derived ECs proliferation in the control group through upregulation of AR, CDK1 and VEGF gene expression. In contrast, DHT did not promote the cellular proliferation of PCOS iPSC-derived ECs at physiological concentrations of 1 and 10 nM and the expression of AR, CDK1, and VEGF remained unchanged. These data suggest that DHT-induced cellular proliferation and the expression of associated genes were more sensitive and dose-dependent in the control iPSC-derived ECs and blunted in the PCOS iPSC-derived ECs.

Limitations, reasons for caution: One of the major limitations of our study was the limited number of cases during the establishment of iPSCs, which was unable to reflect the heterogeneity and complexity of PCOS.

Wider implications of the findings: Impaired cellular proliferation and differentially expressed genes involved in cell proliferation, immune responses, cardiovascular functions, and apoptosis were observed among PCOS iPSC-derived ECs. Additionally, androgen-induced ECs proliferation was blunted in PCOS through a diminished AR/VEGF/cyclin D1 signaling pathway, which might hinder VEGF-dependent vascular repair and probably increase cardiovascular risks.

O-223 Sperm Genome Editing by CRISPR-Cas9 through an Ooplasm-Mediated Approach

A.B. De Jesus[1], P. Xie[1], Z. Rosenwaks[1], G. Palermo[1]

[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York- U.S.A.., U.S.A.*

Study question: Can we edit the sperm genome by CRISPR-Cas9 through an ooplasmic-mediated approach?

Summary answer: The ooplasm-mediated technique induced the decondensation of the male gamete nucleus and allowed CRISPR-Cas9 to access the sperm DNA to carry out successful edits.

What is known already: Previous studies on genome editing using CRISPR-Cas9 have been performed at the S-phase or zygote stage, but challenges were represented by mosaicism and possible off-target edits. To address these issues, gene editing at the gamete level would be ideal. While this may be feasible in oocytes, it appears ambitious in the spermatozoon due to the DNA hypercoiling around the protamine core and the chromatin compaction. In preliminary experiments, permeabilization of sperm membrane allowed penetration of CRISPR-Cas9 to enter the cell, however, genomic editing was proved unsuccessful.

Study design, size, duration: In the past 5 months, a total of 128 oocytes were divided into 2 groups. To edit exclusively the male genome through oocyte-mediated sperm decondensation (OMSD), a single spermatozoon was injected into an enucleated oocyte to produce a haploid androgenetic embryo. The control cohort consisted of embryos generated through standard ICSI with the established heritable genome editing (HGE) approach. Both groups were treated with CRISPR-Cas9 aiming to knockout *Tyr* gene to create an albino phenotype.

Participants/materials, setting, methods: B6D2F1 mice were used to retrieve oocytes and spermatozoa. A cohort of oocytes used for OSMD approach were enucleated. While the intact oocytes were used for HGE control. All oocytes were injected with a single spermatozoon together with CRISPR-Cas9 solution, containing *Tyr* gRNA. All embryos were cultured up to the 8-cell stage. Individual blastomeres were isolated and sequenced to proof editing. DNA was extracted and amplified for T7E1 analysis to validate genome editing efficiency.

Main results and the role of chance: Of the 128 oocytes used for the study, 51 were enucleated for the OMSD experiments, while 77 were used for HGE control. After undergoing ICSI with CRISPR-Cas9 solution, 84.3% (43/51) of the OMSD cohort displayed a single male pronucleus and 79.2% (61/77) control HGE fertilized. In a time-lapse microscopy, 95.3% (41/43) of the OMSD experimental group developed to the 2-cell stage, comparable to the HGE control development at 96.7% (59/61). After 48 hours in culture, the HGE control reached 8-cell development at 88.5% (54/61), while the OMSD cohort cleaved at the lower rate at 60.4% (26/43, $P<0.001$). A 423-bp region around the CRISPR target site was amplified on DNA extracted by isolated blastomere. Gene modification at the target site was confirmed in 33.7% (70/208) of OMSD cohort and 29.7% (88/296) of the HGE control embryos.

Limitations, reasons for caution: While the experimental observations are still limited, it is important to note that these results may be underestimated since embryos with completely uniform modifications may go undetected by T7E1 assay. The technique needs further refinement to optimize targeting efficiency and support embryo development.

Wider implications of the findings: Once the genetic editing method is optimized, individual pseudo-blastomeres generated through this OMSD approach can be utilized as male gametes to fertilize oocyte. The generation of live offspring with the corrected haplotype will serve to prove the safety of genome editing through this technique.

[7]*Instituto Bernabeu Biotech, Andrology, Alicante, Spain*

Study question: Does intraovarian administration of platelet rich-plasma (PRP) increase ovarian response in women with poor ovarian response (POR) undergoing IVF treatment?

Summary answer: In patients with low ovarian response, the number of oocytes and embryos is higher in the 4 cycles after PRP administration compared to pre-PRP cycles.

What is known already: The number of oocytes after controlled ovarian stimulation is a crucial factor in IVF outcomes. For this reason, different approaches have been investigated for the management of patients with POR,

such as the administration of adjuvant treatments, or the change of protocol, dose or type of gonadotropin. However, none of these strategies has proven to be fully effective in improving oocyte yield.

More recently, innovative treatments aimed at activating preantral follicles have emerged, such as intraovarian administration of autologous platelet rich plasma (PRP). Although the evidence is still limited, some studies suggest an improvement in ovarian response following PRP treatment.

Study design, size, duration: Retrospective study of 83 patients diagnosed with low ovarian reserve according to Bologna criteria who underwent intraovarian PRP between July 2021 and December 2022. 111 stimulation cycles after PRP were compared with the cycles immediately prior to PRP administration.

Participants/materials, setting, methods: Patients with POR were presented with an oocyte or embryo preservation strategy, which included the option of administering intraovarian platelet-rich plasma (PRP) either during the initial oocyte retrieval or in the follicular phase of the cycle preceding stimulation. A 2 ml dose of PRP was administered into each ovary. The ovarian response was analyzed in terms of the number of oocytes, MII, and embryos, and was further evaluated based on different age groups.

Main results and the role of chance: 83 women (age: 38,68 ± 3,54, range 28-46 years) underwent a PRP injection. The patients had low ovarian reserve markers (AMH 2,90 ± 2,76 pmol/l, AFC 4,74 ± 2,70).

Of the cycles after PRP, 48 were performed in the luteal phase of the same cycle, 28 in the follicular phase of the first post-PRP cycle and 35 between the 2nd and 4th cycle post PRP.

The overall mean number of oocytes (2,38 ± 2,09 vs. 3,19 ± 2,70; p = 0,002) and MII (1.84 ± 1.77 vs. 2.54 ± 2.25, p = 0.0008) was significantly higher after PRP. There was also a statistically significant difference in the number of blastocysts pre and post PRP (0,85 ± 1,12 vs. 1,77 ± 1,89; p = 0,0005). There were no differences in the blastulation or euploidy rates.

Differences in the number of oocytes were not observed in the luteal phase cycle (2.97 ± 2.35 vs. 3.45 ± 2.66, p = 0.2) compared to the subsequent 1st-4th cycles (1.88 ± 1.77 vs. 2.95 ± 2.73, p = 0.003).

Improvement in response was observed in patients younger than 40 years (2 ± 1.52 vs 3.3 ± 2.62 oocytes; p = 0.0002), but not in patients aged ≥ 40 years (2.9 ± 2.58 vs 3.02 ± 2.77 oocytes; p = 0.7).

Limitations, reasons for caution: The retrospective nature of the study is a significant limitation. As this research is based on real-world clinical practice, the patients stimulation protocols were diverse which may have impacted the results. To verify our findings, further studies with a uniform control group are required.

Wider implications of the findings: We observed improved response to intraovarian platelet-rich plasma administration in patients with POR under 40 years of age. This enhancement was observed from the initial follicular cycle following administration. Our findings suggest that intraovarian PRP may be a valuable supplementary treatment for this patient population.

P-557 Validating the Dutch polycystic ovary syndrome questionnaire (PCOSQ) and the polycystic ovary syndrome quality of life tool (PCOSQOL) in Dutch and Flemish women with PCOS

S. Somers[1], G. Jiskoot[2], C. De Roo[1], D. Stoop[1], J. Laven[2]

[1]Ghent University Hospital, Department of Reproductive Medicine, Ghent, Belgium
[2]Erasmus Medical Centre, Division of Reproductive Endocrinology and Infertility-Department of Obstetrics and Gynecology, Rotterdam, The Netherlands

Study question: What are the test-retest reliability and the domain structures of the Dutch version of the PCOSQ and PCOSQOL in Dutch and Flemish women with PCOS?

Summary answer: The Dutch version of the PCOSQ and the PCOSQOL are reliable and can both be used to measure health-related quality of life (HRQoL) in PCOS.

What is known already: The polycystic ovary syndrome questionnaire (PCOSQ) is recommended to measure the quality of life in women with PCOS. The PCOSQ was developed in 1998 to complement generic health-related QoL instruments. The PCOSQ has been validated in Arabic, German, Chinese, and Swedish. Recent research suggested that the PCOSQ focuses on the physical impact of PCOS and that psychological, social, or environmental aspects are less represented. Therefore, the Polycystic Ovary Syndrome Quality Of Life Scale (PCOSQOL) was developed in 2018. Both questionnaires have not been validated in Dutch yet.

Study design, size, duration: A forward and backward translation was performed on the original English PCOSQ and PCOSQOL by two independent translators. PCOS patients were contacted with a request to complete both questionnaires (and some additional demographic questions) online in their home environment (T0). A test-retest design was applied to demonstrate stability over time by having all women complete the same questionnaires a second time (T1). Approval of the clinic's Ethics Committee was obtained in both participating centres.

Participants/materials, setting, methods: Women of at least 18 years old, who were able to speak and write Dutch, and who were diagnosed with PCOS according to the Rotterdam criteria (ESHRE/ASRM, 2003) or according to the international evidence-based guideline for the assessment and management of PCOS (ESHRE, 2018) were eligible for the study. Women who were pregnant at T0 or T1 were excluded from the study. Participants were included between January and December 2021.

Main results and the role of chance: In total, 245 women were included in this study. The median age was 31 (19-54) years. For the PCOSQ, the Cronbach alpha statistic for the five domains ranged from 0.88 to 0.96 demonstrating good to excellent internal consistency. The Intra-class Correlation Coefficient (ICC) for the five domains was high to excellent ranging from 0.88 to 0.96. For the PCOSQOL, the Cronbach alpha ranged from 0.91 to 0.96 demonstrating excellent internal consistency. The ICC ranged from 0.91 to 0.96 for the four domains indicating excellent reliability. The factor analysis presented five domains of the PCOSQ and the original domain structure was partly confirmed. An extra domain for acne was included based on previous studies. Therefore, the Dutch version of the PCOSQ contained six domains: Weight, Body hair, Emotions, Infertility, Menstrual problems, and Acne. Based on the factor analysis, an extra domain was added to the original four domains of the PCOSQOL, which included items related to dealing with PCOS. Most women (70.6%) needed approximately 15 minutes to complete both questionnaires and had no preference for one of the two questionnaires (55.9%).

Limitations, reasons for caution: A limitation of our study could be that women with more PCOS complaints were more motivated to participate in this study. Therefore, potential selection bias should be taken into account.

Wider implications of the findings: The PCOSQ and PCOSQOL are disease-specific QoL measures for women with PCOS. The Dutch versions can be used in studies and in clinical settings (e.g. by nurses and midwives, counsellors, psychologists) to examine the impact of PCOS on QoL in Dutch and Flemish women.

P-555 Do IVF patients prefer the rectal route to the vaginal for luteal phase progesterone administration? - a cohort study

M. Brix Jensen[1], A. Mikkelsen[1], M. Kyndi[1], P. Humaidan[1,2], B. Alsbjerg[1,2]

[1]Skive Region Hospital, The Fertility Clinic, Skive, Denmark
[2]Aarhus University, Department of Clinical Medicine-, Aarhus, Denmark

Study question: How do IVF patients perceive rectal administration of progesterone for luteal phase support compared to vaginally administered progesterone?

Summary answer: Rectal administration of progesterone causes less discomfort in IVF patients, undergoing Hormone Replacement Therapy Frozen Embryo Transfer (HRT-FET) and is preferred compared to vaginal administration.

What is known already: Progesterone is essential for implantation and normal development of pregnancy in spontaneous pregnancies as well as in ART pregnancies. In IVF, progesterone is most often administered vaginally in Europe for luteal phase support, although, this route may cause cumbersome discharge, vaginal bleeding, and irritation of the vulva. For many years the vaginal route has been the gold standard, although, progesterone is well absorbed rectally and recent studies have shown that rectally administered micronized progesterone was well accepted among IVF patients. Until now, in IVF very little focus has been on patient convenience as regards luteal phase support.

Study design, size, duration: An interventional cohort study, conducted from January 2020 to November 2022 in a public fertility clinic. A total of 479 patients received a questionnaire (Q1) by e-mail during the period between the embryo transfer and the pregnancy test; A second questionnaire (Q2) was answered at the time of the first ultrasound scan in gestational week 7.

Participants/materials, setting, methods: Patients underwent an HRT-FET protocol, including vaginal progesterone (VP) (400mg/12hours). In patients with serum progesterone levels lower than 11 ng/ml on the 6th day of progesterone, additional progesterone was administered rectally (RP) (400mg/12hours) from that day until the day of pregnancy testing, and in pregnant patients until the first scan in week 7.

Side effects and patient convenience of both routes were reported in a questionnaire, including 27 questions, using a visual analog scale (0-100).

Main results and the role of chance: A total of 73% of HRT-FET patients (349/479) answered Q1 before the pregnancy test and a total of 27 % (93/349) of the cohort received progesterone both vaginally and rectally. The response rate of Q2 in gestational week 7 was 100 % (221/221) and a total of 28 % of patients (62/221) administered progesterone both vaginally and rectally.

In Q1, a total of 60% of patients (54/90) preferred RP over VP in the cohort of patients treated with both administration regimens.

In Q2, a total of 62% of patients (37/60) preferred RP over VP in the cohort of patients treated with both administration regimens.

The overall discomfort was lower in relation to RP in both questionnaires and, especially discharge was lower in RP compared to VP; median interquartile range (IQR) in Q1: 11 (3-23) vs. 50 (25-66) and Q2: 19 (9-28) vs. 47 (22-62), respectively. Changes in defecation pattern after RP were reported in Q1 as well as Q2, 48% (45/92) and 55% (34/61), however, the discomfort was reported as mild. An increased flatulence was reported by 50% (46/92) in Q1 and 63% (39/92) in Q2, however, again the discomfort was reported as mild.

Limitations, reasons for caution: Currently, it is unknown whether the present results apply to progesterone products other than the one used in the present study (Cyclogest®). The questionnaire used, although having been used in another published study with another progesterone product, was not specifically validated for this product.

Wider implications of the findings: The rectal route should be remembered for luteal phase support in IVF, and some patients might choose the rectal route over the vaginal for their luteal phase support due to less discharge.

Trial registration number: EudraCT no.: 2019-001539-29

P-556 Digital platform for remote pre-treatment assessment: Perceived usefulness and quality by patients and doctors

A. De Oliveira Trigo[1], B. De Oliveira Trigo[2], F. Khan Sullivan[3], N. Felix[3], M. Fanti[4]

[1]Enhanced Fertility, Nurse, London, United Kingdom
[2]Enhanced Fertility, Psychologist, London, United Kingdom
[3]Enhanced Fertility, Technology, London, United Kingdom
[4]Enhanced Fertility, Marketing, London, United Kingdom

Study question: Is a digital platform for remote pre-treatment assessment perceived as useful and able to fulfil the needs of patients and clinicians?

Summary answer: The digital platform was found to be of high quality, useful, and answer the expressed needs of the targeted audiences in cross-cultural samples.

What is known already: Infertility is a life crisis. It takes on average 3.2 years to be diagnosed, 1.6 years to access a specialist, and 2.2 years to complete treatment. The pre-assessment phase is time-consuming, costly, often disruptive to the patient's life, and may require traveling abroad. Patients need organized care where they can schedule/order tests, access information about their specific health conditions, and reach out to professionals. On the other hand, clinicians find themselves trying to assess a large number of patients before initiating treatment abroad without having a unified platform where they can review the patient's clinical history and treatment plan.

Study design, size, duration: Study I explored patients' experience with pre-treatment care and their perceived usefulness of the Patient's Portal. An online questionnaire of 25 questions was used. Study II explored clinicians' perceived usefulness and quality of the Doctor's Portal. A semi-structured interview was conducted and an online questionnaire of 17 items was used. Both questionnaires had multiple options, Likert-scale, and open-ended items. The studies followed a cross-sectional design. The data were analyzed using IBM SPSS Statistics, Version 28.0.

Participants/materials, setting, methods: Study I had a cross-cultural sample of 59 women (M = 37.2, SD = 4.9 years). 41% are trying to conceive for more than 24 months, 89.8% were in a heterosexual relationship, and all were undergoing treatment/pursuing a clinic. The internal consistency of the questionnaire is α=.97. Study II had a cross-cultural sample (N = 8) of clinic leaders, all from different clinics. The interview questions were open-ended to capture unprompted opinions. The internal consistency of the questionnaire is α=.94.

Main results and the role of chance: Study I: People who took >4 weeks to have tests done/get the results scored significantly higher values than people who took less time in terms of how much they had to pay, struggled to find where to have the tests done, had difficulty managing emotions, and would've preferred their clinic had scheduled the testing for them. Overall, 61.02% reported the testing had been disruptive to their lives. Regarding the perceived usefulness of the platform, means >4 and a mode of 5 on a scale of 1-5 were obtained. We also found that regardless of the woman's age or how long she's been trying to conceive, she'd benefit from having this platform available.

Study II: 75% made mention the high-quality of the platform, 50% said it would improve their current practice, covered information comprehensively, and was user-friendly, and 37.5% said it would make the process of diagnosing patients faster. Suggestions were used to adapt the platform. Regarding the quality questionnaire, the means varied between 7.86 and 9.14 (SD between .69 and 1.11) and the mode between 8 and 9 on a scale of 1-10. The inter-rater reliability coefficient was .94. This means the perceived high-quality and usefulness of the platform were consensual.

Limitations, reasons for caution: Small sample sizes condition the extrapolation of the findings. Further studies of the perceived usefulness and quality of the Patients' Portal and Doctors' Portal after the implementation of the digital platform are required.

Wider implications of the findings: The digital platform for remote pre-treatment assessment is currently available and being used by clinicians and patients. In the future it, can be further developed to develop and train an

Artificial Intelligence algorithm to Diagnose & Predict Fertility Treatment Outcomes with Personalised Patient Pathways.

P-560 Stigma related to male infertility in China: a scale development and validation study

F. Zou[1], **Y. Lin**[1], **S. Hang**[1], **G. An**[1], **M. Cao**[1], **J. Liu**[1]

[1]*The Third Affifiliated Hospital of Guangzhou Medical University, Center for Reproductive Medicine, Guangzhou, China*

Study question: Is it possible to develop a trustworthy instrument to evaluate the infertile men's stigma and to document fully all methodological steps, including validation?

Summary answer: The Male Infertility Stigma Scale (MISS) has been developed to evaluate the stigma status of infertile men with a good reliability and validity.

What is known already: Infertile men regard childless as a hidden stigma, which influence all the dimensions of their lives and well-being. Most instruments focus exclusively on women and no questionnaires have been directed at infertile men.

Study design, size, duration: A cross-sectional study was conducted to analyse the validity and reliability of MISS. This was a one-centre study in the Center of Reproductive Medicine of the Third Affiliated Hospital of Guangzhou Medical University between January 2019 to May 2019.

Participants/materials, setting, methods: This study was carried out on men (n = 432) with a diagnosis and treatment for male-factor infertility. Item generation and reduction of MISS was formed by combining literature review, interviews of experts and patients, and related scale. Exploratory factor analysis (n = 216) and confirmatory factor analysis (n = 216) were performed to indicate the scale constructs. In addition, reliability analyses including internal consistency and test–retest analysis (n = 18)were carried out. Validity was analyzed by convergent validity and content validity.

Main results and the role of chance: This study developed a 18-item MISS with three dimensions (social marginalization, self-devaluation, psychological insecurity). Exploratory factor analysis indicated that these three dimensions explained 60.14% of total variances.The confirmatory factor analysis showed that the construct of the MISS fitted well with the hypothetical model. The Cronbach's α,split-half coefficient and test–retest correlation coefficient for the whole scale was 0.951, 0.884,and 0.945, respectively. The associations of the MISS with other measure suggested good convergent validity. The Content Validity Index (CVI) was 0.988.

Limitations, reasons for caution: The reliability and validity of the MISS developed in this study were verified only among the infertility men in Guangzhou and the discriminant validity of dimension 3(psychological insecurity) in this survey was a little poor. The convenience sampling method precluded the validity and generalization of the conclusions.

Wider implications of the findings: This study may create an effective evaluation measurement to understand the stigma status of infertile men. Future studies should focus on using the MISS in larger samples with different characterizations, such as different areas, and then taking some measures to help them .

O-225 May embryonic cfDNA in the culture media play a role as a non-invasive assessment of aneuploidy in PGT

C. Rubio LLuesa[1]

[1]*Igenomix, Research and development, Valencia, Spain*

Non-invasive preimplantation genetic testing for aneuploidies (niPGT-A) in spent blastocyst media (SBM) is a promising technique that has the potential to revolutionize current preimplantation genetic testing procedures. This technique is based in the analysis of the cell-free DNA (cfDNA) released by the embryo during the latest stages of preimplantation development. It allows for the detection of chromosomal abnormalities in embryos without the need for invasive procedures that can harm the embryo (reviewed in Navarro-Sánchez et al., 2022).

Our group among others has conducted different studies in this field, and the early clinical application of the cfDNA analysis in the culture medium has been proposed as a screening tool, giving a priority score for embryo transfer based on the media results (Rubio et al., 2019, 2020). In the final analysis of our multicenter study in day-6 and day-7 blastocysts, we have been able to compare the chromosomal results of the SBM with trophectoderm (TE) biopsies in 2,187 samples, and with the inner cell mass ICM in 230 blastocysts. In this study, the analysis of the cfDNA showed a concordance rate of 87% with the ICM biopsy, which is currently considered the gold standard for PGT-A. However, it is important to continue evaluating the factors that may affect the informativity and concordance rates of cfDNA-based assays, such as the culture day when medium is collected, contamination with external and/or cumulus cell DNA, and previous manipulation of the embryos. Multivariate analysis has shown that the longer the time in culture, the higher the informativity rate, and female age had the greatest impact on concordance rates with TE biopsies. Regarding technical aspects, the SBMs with higher number of reads after sequencing resulted in higher concordance rates, reflecting the importance of analysing samples with sufficient DNA quantity. Finally, the predictive value in terms of concordance with TE biopsies was higher for aneuploid blastocyst. No significant independent correlation was observed for embryo quality.

The improvements in IVF lab protocols and the use of time-lapse and short incubation protocols for vitrified-thawed blastocysts are also noteworthy, as they may further increase the concordance rates of cfDNA-based assays with blastocysts. In fact, concordance in previously vitrified-thawed blastocysts as result as high as 90%.

Regarding clinical outcomes, several groups have evaluated non-invasive PGT-A with transfer of euploid embryos showing good results. In a pilot study with only 7 SETs in couples with PGT-A or PGT-SR indication, 5 pregnancies were achieved resulting in 5 livebirths (Xu et al., 2016). In a second study, in couples with recurrent spontaneous abortion or repeated implantation failure, 50 transfers of euploid media were performed resulting in a 58% clinical pregnancy rate, with 27 healthy babies born (Fang et al., 2019). Similar results were described in good prognosis patients <38 years of age with ongoing pregnancy rates comparable to PGT-A (61.5%), and higher than conventional IVF or ICSI (48.5%) (Franco et al., 2021).

Overall, the high concordance rates with trophectoderm biopsies and inner cell mass biopsies are encouraging, and the clinical outcomes with transfer of euploid embryos are promising. It is exciting to see the progress in non-invasive preimplantation genetic testing using cfDNA in culture medium, and it will be interesting to see how this technology evolves and its potential role as a screening or diagnostic tool in the future.

O-226 Is there a place for polygenic risk scoring in PGT (PGT-P)?

A.H. Handyside[1]

[1]*University of Kent, School of Biosciences, Canterbury, United Kingdom*

Preimplantation genetic testing (PGT), by embryo biopsy and genetic testing for inherited diseases and chromosome abnormalities following IVF, is now well established world-wide. PGT for monogenic conditions (PGT-M) is generally performed for childhood-onset, lethal disorders, but is increasingly accepted for certain adult-onset conditions, conditions with available treatment options or conditions with lower penetrance. Over recent years, machine learning methods applied to large genomic datasets, including genome-wide association studies (GWAS) using single nucleotide polymorphism (SNP) genotyping, has enabled polygenic risk scores (PRSs) to be calculated to identify individuals who are at elevated risk for a broad range of conditions including important common multifactorial diseases, such as coronary artery disease (CAD), diabetes, hypertension and various cancers. It is now possible to perform genome-wide SNP genotyping of embryo biopsy samples with the same accuracy as adult genomic DNA and the first live birth following PGT for polygenic risk scoring (PGT-P) was reported in 2019 (Treff et al (2019) Front Endocrinol 10, 845) . The clinical application of PGT-P is controversial and raises many practical, ethical and societal issues. To examine the question 'is there a place for PRS in PGT', the example of predisposition to breast cancer will be reviewed.

O-227 Viral, bacterial and fungal infections in patients with recurrent miscarriage

J. Laven[1]

[1]*Erasmus Medical Center, Div reproductive Endocrinology and Infertility- Dept. Obstetrics and Gynaecology., Rotterdam, The Netherlands*

Miscarriages occur in 15% of clinically recognized pregnancies in the general population. Miscarriage has several physical and psychological consequences and might be a risk marker of severe obstetrical complications during the following pregnancies and various long-term pathological conditions, such as venous thromboembolism and cardiovascular diseases. Up to 80% of reproductive losses occur in the first trimester. Miscarriage may be caused by chromosomal abnormalities, antiphospholipid syndrome and other thrombophilia's, immune and endocrine disorders as well as inflammation. However, in up to 50% of cases, the cause of the miscarriage remains unknown.

The microbiome consists of microbes that are both helpful and potentially harmful. Most are symbiotic and some, in smaller numbers, are pathogenic. In a healthy body, pathogenic and symbiotic microbiota coexist without problems. But if there is a disturbance in that balance brought on by infectious illnesses, certain diets, or the prolonged use of antibiotics or other bacteria-destroying medications dysbiosis occurs, stopping these normal interactions. In this presentation the role of the microbiome as well as the virome in recurrent miscarriage will be discussed. Possible mechanism of action will be reviewed and, if available, treatment of a perturbed microbiome will be presented.

O-228 Dysbiosis and reproduction

H. Svarre Nielsen[1]

[1]*Copenhagen University Hospital, Obstetrics and Gynaecology, Hvidovre, Denmark*

Bacteria, viruses, and fungi are collectively known as our microbiome and constitute approximately 1-2% of our body weight. The microbiome is closely associated with our health. Dysbiosis refer to a suboptimal microbiome composition and while gut dysbiosis has been extensively investigated there is far less studies on how the reproductive microbiome is associated with reproductive health. This presentation will cover definitions, methods, and give an overview of the studies that have investigated the association between gut, vaginal and endometrial microbial dysbiosis and the association with implantation and early pregnancy. Possible mechanisms and treatment options will also be adressed.

INVITED SESSION

SESSION 74: GUIDELINES SESSION: PCOS – UPDATE OF THE INTERNATIONAL GUIDELINES

Wednesday 28 June 2023 Hall D1 08:30 - 09:30

Abstract citation ID: dead093.279
O-229 Long term features of PCOS and Medical treatment

T. Piltonen[1]

[1]*University of Oulu, Obstetrics and Gynecology and Reproductive Endocrinology, Oulu, Finland*

Objective: To develop and translate comprehensive evidence-based guidelines for diagnosis, assessment and treatment, to improve the lives of those with polycystic ovary syndrome (PCOS) worldwide.
Participants: Health professional and consumer/ patients informed priorities. International society-nominated panels included consumers, and experts in reproductive endocrinology, obstetrics, gynaecology, paediatrics, endocrinology, primary care, psychology, dietetics, exercise physiology, sleep, bariatric/ metabolic surgery, public health, other co-opted experts, evidence synthesis and translation.
Evidence: Best practice guideline development involved extensive evidence synthesis and the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) framework covered evidence quality, feasibility, acceptability, cost, implementation and recommendation strength.
Process: Governance included international advisory and project, guideline development, consumer and translation committees. The Centre for Research Excellence in Women's Health in Reproductive Life, funded by the Australian National Health and Medical Research Council (NHMRC), and led by Monash University, partnered with the American Society for Reproductive Medicine, Endocrine Society, European Endocrine Society and European Society of Human Reproduction and Embryology. Another 30 collaborating organisations engaged. Overall 52 systematic and three narrative reviews, informed international guideline groups, generating evidence-based and consensus recommendations and practice points for 55 clinical questions. Collaborating/ partnering organisations and NHMRC methodological experts led peer review.
Recommendations: After diagnosing PCOS, assessment and management should include reproductive, metabolic, cardiovascular, dermatologic, sleep and psychological features. A reproductive health plan is recommended including diagnosis and support in adolescence, lifelong healthy lifestyle / prevention of weight gain, fertility optimisation, preconception risk mitigation and recognition of PCOS as a high-risk pregnancy condition requiring identification, screening, monitoring and management. Metabolic risk factors, diabetes, cardiovascular disease and sleep disorders are increased in PCOS, with screening and management recommended. Increased premenopausal endometrial cancer risk should be recognised. Depressive and anxiety symptoms

are significantly increased, with universal screening recommended. Greater awareness of psychological features including eating disorders, body image and quality of life impacts is recommended. Life-style intervention is the first line treatment for PCOS, but in many cases medication is also needed. Combined oral contraceptive pills are first line pharmacological treatment for menstrual irregularity and hyperandrogenism, with no specific recommended preparation, and a preference for lower dose and less side-effects. Metformin is recommended primarily for metabolic features noting greater efficacy than inositol, which offers more limited clinical benefits. Metformin is not routinely recommended for use in pregnancy. Laser therapy is effective and recommended for hair reduction in identified subgroups, whilst anti-androgens have more limited recommendations. Anti-obesity agents and bariatric/ metabolic surgery may be considered based on general population guidelines, balancing benefits and side effects. Overall, evidence was low to moderate quality. Based on high prevalence and significant health impact, greater priority, education, funding and research is strongly recommended.

O-232 Extracellular vesicles secreted by the maternal endometrium functionally regulate processes related to embryo development and implantation in human blastocysts

M. Segura-Benitez[1], **M.C. Carbajo-Garcia**[1], **A. Quiñonero**[2], **M.J. DeLos Santos**[3], **A. Pellicer**[4], **H. Ferrero**[2]

[1]*Universidad de Valencia, IVI Foundation, Valencia, Spain*
[2]*IIS La Fe, IVI Foundation, Valencia, Spain*
[3]*IVIRMA Valencia, IVF Laboratory, Valencia, Spain*
[4]*IVIRMA Rome, Reproductive Medicine, Rome, Italy*

Study question: What is the response of human embryos in a transcriptomic level to the uptake of extracellular vesicles (EVs) secreted by the human endometrium?

Summary answer: EVs secreted by the maternal endometrium induce a transcriptomic response in human embryos that modulates molecular mechanisms related to embryo development and implantation.

What is known already: Communication between the maternal endometrium and the embryo is essential for a successful implantation, and EV role in this cross-talk has been recently established. Results of our previous experiments showed that endometrial EVs carry miRNAs and proteins related to endometrial receptivity, embryo implantation process and early embryo development, and that they can be uptaken by human blastocysts. However, there are no studies which address the transcriptomic response of human embryos to the uptake of these EVs, which would demonstrate the functional relevance of this communication system.

Study design, size, duration: Endometrial biopsies were collected from oocyte donors (n = 20) with confirmed fertility, on oocyte retrieval day, and primary human endometrial epithelial cells (pHEECs) were isolated and *in vitro* cultured. Hormonal treatment was added to mimic secretory phase of menstrual cycle. Conditioned medium was collected and EVs were isolated and characterized. Day 5 human blastocysts (n = 24) were divided into two groups (n = 12/group) and cultured *in vitro* with or without these EVs. RNA-sequencing of these embryos was performed.

Participants/materials, setting, methods: Conditioned media from pHEECs was pooled into 4 replicates (n = 5 biopsies/replicate) and EVs were isolated by ultracentrifugation. Characterization was performed by western blot, nanoparticle tracking analysis and transmission electron microscopy (TEM). Human blastocysts were devitrified and cultured in vitro for 24h with or without EVs previously isolated. RNA-sequencing analysis was performed, and DESeq2 was used to identify differentially expressed genes (FDR<0.05). QIAGEN Ingenuity Pathway Analysis (IPA) was used to perform the functional enrichment analysis.

Main results and the role of chance: EVs presented a size range within 100-300nm, and expression of EV protein markers HSP70, TSG101, CD9 and CD81. EV morphology was corroborated by TEM. RNA-sequencing identified 26610 genes, being significant 519 upregulated and 395 downregulated in EV-embryos compared with control. Among top20 most significant upregulated genes, CSF1R (log2FoldChange [logFC]=3.36) has been associated with formation of blastocyst cavity, and PLOD2 (logFC=2) deficiency leads to early embryonic lethality. Genes related to antioxidant defense, as PDK1 (logFC=2.82), or vesicle trafficking, as SEC24D (logFC=2.17), were also upregulated. Regarding top20 downregulated genes, DAB2IP (logFC=-1.19) negative regulation was found beneficial in early pregnancy, and DUSP6 (logFC=-2.07) was associated with cell differentiation and pluripotency. Functional analysis demonstrated positive regulation of biological processes related to embryonic development, cellular invasion and migration, cell cycle, cellular organization, and cell viability in EV-embryos. Contrary, there was a negative regulation of processes related to cell death, apoptosis, and DNA fragmentation. Some pathways upregulated in EV-embryos were NANOG role in embryonic pluripotency (z-score [z]=1.89), unfolded protein response (z = 3.05), involved in cellular homeostasis, VEGF signaling (z = 1.67), that regulates trophoblast adaptation to hypoxia, and integrin signaling (z = 3.36), which regulates trophoblast adhesion and differentiation; PTEN signaling (z=-1.73) was inhibited in EV-embryos, suppression of which prevents apoptosis.

Limitations, reasons for caution: This is an *in vitro* study in which conditions of endometrial cell culture could not mimic the intrauterine environment.

Wider implications of the findings: EVs secreted by the maternal endometrium and uptaken by human blastocysts regulate processes related to embryo development and implantation, suggesting the functional relevance of this endometrial-embryo crosstalk during the implantation process. This study opens further research insight to define potential targets of implantation success and embryo competence.

Study question: What characteristics and features of follicular fluid (FF) extracellular vesicles (EVs) of women of different ages can affect the functional characteristics of spermatozoa?

Summary answer: The size, lipid composition, and progesterone levels of the FF EVs change with a woman's age and affect the fertilizing ability of spermatozoa.

What is known already: Aging influences on molecular composition of the FF, reducing fertilization processes occurring in the fallopian tubes. FF is an important factor in activating spermatozoa during oocyte fertilization, enhancing the process of sperm hyperactivation and capacitation. FF progesterone is one of the main chemoattractants in the female genital tract, attracting sperm to the oocyte and starting the fertilization processes. Our previous studies have shown a significant effect of FF EVs of young women compared to advanced maternal age women (AMA) on the hyperactivation and motility of spermatozoa. The binding of FF EVs to the acrosoma of the sperm also was detected.

Study design, size, duration: FF EVs were obtained by sequential centrifugation at different rotational speeds. The sperm fraction was isolated, washed by differential centrifugation in a density gradient, suspended in the saline to a concentration of 10*6/ml and incubated with EVs (1:2) at 37 °C in CO2-incubator for 1 h. Next steps: immunofluorescent staining, test for acrosomal reaction of spermatozoa after incubation, NTA analysis, the lipid profile and progesterone measuring of FF EVs of women of different ages.

Participants/materials, setting, methods: All study participants signed a voluntary informed consent for the use of biological samples for research purposes. Sperm samples were isolated from seminal fluid (n = 21) aged 28-36. FF EVs were obtained from young (n = 14) aged 22-30 and AMA patients (n = 14) aged 42-47. The methods used in this work also include immunofluorescence microscopy, nanoparticle tracking analysis, flow cytometry, liquid chromatography–mass spectrometry, statistical data analysis. Lipids were extracted from EVs using a modified Folch extraction protocol.

Main results and the role of chance: Progesterone levels were significantly higher in FF EVs samples from young women compared to FF EVs samples from AMA women and controls (3951000 a.u., 598500 a.u., 6701 a.u.). This may explain the increase in sperm hyperactivation and motility after incubation with FF EVs. The difference in size (144.78 nm ± 9.92 VS 127.03 nm ± 17.17) and lipid composition of young women's FF EVs may explain the more significant functional and therapeutic effect on spermatozoa compared to AMA women FF EVs. A total of 389 vesicle lipids were identified. The level of cholesterol esters, cholesterol, lysophosphatidylcholines, phosphatidylcholines was 1,5 times higher in FF EVs of young women. The level of di- and triglycerides, ceramides, oxidized forms of phosphatidylcholines was higher in FF EVs of AMA women. The level of spontaneous acrosomal reaction was almost 3 times lower in sperm samples after incubation with FF EVs compared to the control (11,21% VS 32,88%). This supports the hypothesis that FF EVs may restrain premature acrosomal reaction in the fallopian tubes. Age-related changes are reflected in reproductive important biological processes, which leads to a change in the composition and functions of FF and affect the functional role of FF EVs.

Limitations, reasons for caution: Small amount of data. To be completely confident in the importance of the participation of FF EVs in the activation of spermatozoa, it is necessary to perform proteomic analyses of FF EVs to discuss the possible mechanisms underlying the effects of FF EVs of different age groups on sperm characteristics.

Wider implications of the findings: Further studies may help not only to complement the fundamental understanding of the processes of fertilization and the impact on spermatozoa morphofunctional characteristics, but also to develop a tool for improving ART outcomes in couples with male infertility. The solutions could be the use of FF EVs from young donors.

[4]Vattikuti Urology Institute- Henry Ford Health, Urology Department, Michigan, U.S.A.
[5]American Center for Reproductive Medicine, Global Andrology Forum, Ohio, U.S.A.

Study question: Does constant supplementation of antioxidants to the culture media increase blastocyst formation from oocyte donors?

Summary answer: The constant supplementation of antioxidants to the culture media increases blastocyst formation from oocyte donors

What is known already: The use of a combination of various antioxidants in embryo culture media has recently been investigated to explore the potential benefit for embryo development and clinical outcomes. However, the concentration of antioxidants added to the culture has only been determined by its effect. In this study, we performed a repeated antioxidants supplementation to resemble a physiological oxidation reduction environment. Therefore, we investigated the effect of antioxidants added every 12 hours to the culture media on blastocyst formation and expansion in oocyte donors.

Study design, size, duration: This prospective study was conducted at CITMER, Mexico from April 2020 to November 2022.We included a total of 258 recipients from oocyte donors undergoing IVF/ICSI.

Participants/materials, setting, methods: A total of 2403 zygotes were divided into 4 groups and cultured in the following conditions until blastocyst stage: Group 1A: 563 zygotes 20% O2 with antioxidants every 12 hours, Group 1B: 1109 zygotes 20% O2 with antioxidants at the beginning, Group 2A: 339 zygotes 5% O2 with antioxidants every 12 hours, Group 2B: 392 zygotes 5% O2 with antioxidants at the beginning. Embryo development was assessed. Odds ratio and Fisher test were performed. $p < 0.05$=significant

Main results and the role of chance: For both oxygen tensions, we found a significant increase in the total blastocyst formation rate (day 5+day 6) when antioxidants were added repeatedly (1A: 54.7% vs 1B: 45.9%, p = 0.0007*; 2A: 58.7% vs 2A: 46.9%, p = 0.001*). In addition, the rate of expansion at days 5 + 6 was also significantly higher than in the groups where the antioxidants were added only at the beginning of the culture (1A: 35.9% vs 1B: 29.9%, p = 0.01*; 2A: 41.3% vs 2A: 31.6%, p = 0.006*).

Limitations, reasons for caution: Given this is a sibling zygotes study, patients are their own controls.

Wider implications of the findings: Constant supplementation of antioxidants to the culture media increases blastocyst formation from oocyte donors as well as the expansion rate, which may significantly improve clinical outcomes.

O-235 Antioxidants in culture media improve ICSI fertilisation rate: results from a randomised controlled trial

R. Kelley[1], L. Lee[1], F. Agresta[1], A. Huang[1], J. Sgroi[1], G. Rozen[1], A. Polyakov[1], L. Hale[1], R. Lew[1], C. Stern[1], M. Toledo[2], F. Cattrall[1], D. Gardner[1]

[1]Melbourne IVF, Melbourne IVF, East Melbourne, Australia
[2]TasIVF, TasIVF, Hobart, Australia

Study question: Does addition of three antioxidants to G-Series media during gamete collection, insemination, and embryo culture increase the clinical pregnancy rate from fresh blastocyst transfers?

Summary answer: Antioxidants increased the ICSI fertilization rate, and consequently the number of blastocysts utilised, but the clinical pregnancy rate from fresh blastocyst transfers was not affected.

What is known already: Supplementation of IVF media with a combination of three antioxidants known as A3 (10 µmol/l acetyl-L-Carnitine, 5 µmol/l α-Lipoic acid and 10 µmol/l N-acetyl-L-cysteine) is beneficial in mouse IVF, embryo culture and cryopreservation, and improves post-transfer outcomes. Further, in a prospective randomised trial on sibling oocytes, addition of A3 to G-1/G-2 media (Vitrolife, Sweden) resulted in more good quality embryos on day 3 (Gardner et al., 2020). The study was not powered to determine the effect of A3 on pregnancy rate, but an increase in ongoing pregnancy rate was observed in women aged 35-40 years following frozen blastocyst transfer.

Study design, size, duration: Single-centre, prospective randomised controlled trial, superiority study comparing G-series media (G-MOPS, G-IVF and G-TL (Vitrolife)) with or without the addition of A3 from January 2019 to November 2021. 1482 patients were randomized before egg collection. Patients and their doctors were blinded to the treatment group. The primary endpoint was clinical pregnancy per randomised couple from the fresh transfer of a single blastocyst.

Participants/materials, setting, methods: Patients undergoing IVF/ICSI cycles and intending to undergo a fresh transfer of a single blastocyst were recruited. Exclusion criteria were previous participation in the study, freeze-all cycle, or extraction of sperm from testicular biopsy. 743 patients were randomised to the A3 media, 739 to the control.

Main results and the role of chance: Patients randomised to A3 media had significantly higher fertilisation rate per inseminated oocyte (64.4 ± 25.6%) compared to the control (59.2% ± 26.3%, $P < 0.001$). This was more pronounced in patients undergoing ICSI (68.1% ± 24.9% vs 57.9% ± 27.2%, $P < 0.0001$), where the number of cycles with failed fertilisation decreased from 8.0% to 3.9% with A3 media ($P < 0.05$). There was no effect of A3 on fertilisation rate following IVF. Blastocyst development rate was unaffected by A3, but the higher fertilisation rate resulted in more blastocysts available for transfer or cryopreservation per patient in the A3 group (3.06 ± 2.97 vs 2.67 ± 2.60, $P < 0.01$). Clinical pregnancy rate from fresh cycles was not different between the control (26.1%) and A3 media (23.0%; $P > 0.05$; RR 0.88, 95% CI 0.73-1.05). When patients who did not have a fresh transfer were excluded (due to freeze-all or no embryo available), there was also no difference between the control (35.8%) and A3 media (32.6%; $P > 0.05$; RR 0.91; 95% CI 0.77-1.08).

Limitations, reasons for caution: This was a single-centre study, so the effects of A3 supplementation in clinics with different media and protocols are unknown. Detection of fetal heart by ultrasound was the primary endpoint, birth outcomes are currently being investigated. Outcomes of frozen embryo transfers and cumulative pregnancy rates are yet to be determined.

Wider implications of the findings: Addition of antioxidants to media during gamete collection, incubation and ICSI can increase fertilisation rate and reduce the frequency of failed fertilization cycles. This results in more blastocysts available for transfer and cryopreservation per egg collection, potentially leading to higher cumulative pregnancy rates.

O-236 Fatty acid supplementation into warming solutions improves pregnancy outcomes after single vitrified-warmed cleavage stage embryo transfer

A. Amagai[1], K. Ezoe[2], T. Miki[2], K. Shimazaki[1], T. Okimura[1], K. Kato[3]

[1]*Kato Ladies Clinic, IVF Laboratory, Tokyo, Japan*
[2]*Kato Ladies Clinic, R&D Division, Tokyo, Japan*
[3]*Kato Ladies Clinic, Gynecology, Tokyo, Japan*

Study question: Does fatty acid (FA) supplementation into warming solutions affect pre-implantation development, outgrowth competence, and clinical outcomes of human vitrified cleavage stage embryos?

Summary answer: FA-supplemented solutions improve morphology and outgrowth of blastocysts derived from vitrified cleavage stage embryos and pregnancy outcomes after single vitrified-warmed cleavage stage embryo transfer (SVCT).

What is known already: Vitrification procedure decreased the intracellular lipid content and subsequent developmental competence. Furthermore, a recent study reported that FA supplementation into warming solutions increased intracellular lipid content and improved developmental competence by stimulating the beta-oxidation pathway in mice and bovines. However, in humans, the effects of FA addition to warming solutions on developmental competence and morphokinetics during the pre-implantation period remain unknown. Additionally, the efficacy of FA supplemented warming solutions in clinical settings has not yet been evaluated.

Study design, size, duration: A total of 217 discarded human vitrified 4-cell stage embryos donated for research by consenting couples were randomly allocated, to be warmed in solutions either with (FA, n = 111) or without FA (control, n = 106). Embryonic development, morphokinetics, and trophoblast migration were experimentally compared between the groups. Furthermore, a total of 701 clinical records of women who underwent SVCT between April and September 2022 were retrospectively analysed (control, April–June; FA, July–September).

Participants/materials, setting, methods: Discarded 4-cell stage embryos were warmed and cultured for 72 h in a time-lapse incubator. Furthermore, the blastocysts produced were plated on fibronectin-coated dishes and cultured to assess blastocyst adhesion and outgrowth. In the clinical study, vitrified cleavage stage embryos were warmed in solutions with or without FA and transferred on day 2 after ovulation in the natural cycle. The rates of implantation, clinical pregnancy, and ongoing pregnancy were compared between the groups.

Main results and the role of chance: The developmental rates were comparable between the groups. However, the rate of morphologically good blastocysts was significantly higher in the FA group than in the control group ($P = 0.0089$). The developmental timings were comparable between the groups during all stages. Additionally, the incidence of abnormal cleavages, amount of fragmentation at the cleavage and morula stages, and incidence of blastomere exclusion or extrusion during peri-compaction were comparable between the groups. Further, the blastocyst adhesion rate after outgrowth culture was also comparable between the groups. However, the outgrowth area was significantly larger in the FA group than in the control group ($P = 0.0438$). In the clinical study, the characteristics of the patients and transferred embryos were comparable between the groups. The implantation, clinical pregnancy, and ongoing pregnancy rates were higher in the FA group than in the control group ($P = 0.0252$, $P = 0.0223$, and $P = 0.0281$, respectively). Multivariate logistic regression analysis demonstrated that the probability of ongoing pregnancy was significantly higher in the FA group than in the control group (adjusted odds ratio, 1.46; 95% confidence interval, 1.02–2.06; $P = 0.0340$). The rate of miscarriage during the first trimester was comparable between the groups.

Limitations, reasons for caution: This study has some limitations owing to its retrospective design. Further prospective studies are required to validate the clinical efficacy of FA-supplemented solutions. Furthermore, the effects of adding FA to warming solutions on maternal and perinatal outcomes should be assessed in the future.

Wider implications of the findings: FA supplementation into warming solutions would improve the clinical outcomes of frozen embryo transfers, leading to a shortened treatment period and reduced patient burden in assisted reproductive technologies.

P-439 Intimate hygiene practices and the correlation with abnormal vaginal microbiota in in vitro fertilization (IVF) patients – a cohort study in 1421 patients

S. Ovesen[1], T. Haahr[1], M. Brix[1], J.S. Jensen[2], B. Alsbjerg[1,3], M. Tanderup[1], A. Mikkelsen[1], L. Prætorius[4], A. Pinborg[5], N.L.C. Freiesleben[4], P. Humaidan[1,3]

[1]Skive Fertility Clinic, The Fertility Clinic- Skive Regional Hospital, Skive, Denmark
[2]Statens Serum Institut, Statens Serum Institut, Copenhagen, Denmark
[3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark
[4]Fertility Clinic Hvidovre, Copenhagen University Hospitals, Hvidovre, Denmark
[5]The Fertility Clinic Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Study question: What are the intimate hygiene practices of women in IVF treatment and do they correlate with the vaginal microbiota?

Summary answer: Hygiene practices, in specific douching and use of intimate soap significantly increased the risk of abnormal vaginal microbiota (AVM).

What is known already: The normal vaginal microbiota acts as a defense system against infection. AVM is a molecularly defined vaginal dysbiosis, resembling bacterial vaginosis (BV) and is dominated by anaerobic bacteria such as Gardnerella vaginalis. Importantly, AVM is associated with an increased risk of genital tract infections, poor IVF outcomes, early miscarriage and preterm labor.

The cause of AVM is multifactorial and hygiene practices may interrupt the normal microbiota. Previous small studies suggested vaginal douching to be associated with an increased risk of AVM. Few studies have investigated the possible correlation between intimate hygiene practices, menstrual practices and the vaginal microbiota.

Study design, size, duration: Observational cohort study, including a total of 1421 IVF patients from four Danish fertility centers. The inclusion period was from 2017 to January 2022.

Participants/materials, setting, methods: Patients aged 18-42 years and undergoing their first, second or third IVF stimulation cycle were eligible for inclusion. The intimate hygiene practices in terms of type of soap, menstrual protection, douching and probiotics, were reported in a structured questionnaire including a total of 40 questions. Vaginal swabs were obtained prior to ovarian stimulation and subsequently subjected to quantitative PCR testing, targeting DNA of dysbiotic bacteria.

Main results and the role of chance: AVM was present in a total of 34 % (479/1421) of women, and 20% (272/1384) reported vaginal douching, which significantly correlated with AVM ($p < 0.01$, OR = 1.62 [1.23-2.12]). Intimate soap was used by 39 % (535/1384) of patients, which also significantly increased the risk of AVM ($P = 0.04$, OR = 1.35 [1.08-1.69]). Water only was used by 36% (492/1384), and regular soap was used by 27% (374/1384). No correlation between use of water only and regular soap and AVM was detected. For menstrual protection 40% (433/1078) used pads, followed by tampons alone 25% (265/1078) or a combination 21% (230/1078), and 14 % (148/1078) used a menstrual cup. A trend for an increased risk of AVM when using tampons, OR 1.21 [0.91-1.62] was seen whereas use of a menstrual cup seemed to lower the risk of AVM, OR 0.71 [0.48-1.04]

Active smoking, higher BMI, drinking >7 units per week and previous chlamydia infection significantly correlated with AVM ($p = 0.01$, $p = 0.01$, $p = 0.04$ and $p = 0.01$).

Finally, 84% (1190/1421) reported gynecological symptoms such as vaginal discharge, dyspareunia and fungal infection, but only fishy odor significantly correlated with AVM ($p < 0.01$).

Limitations, reasons for caution: To the best of our knowledge, this is the largest study investigating the intimate hygiene practice and its correlation with AVM in an IVF population. As these results describe the practices of a Scandinavian IVF population, results may differ from other settings and ethnicities.

Wider implications of the findings: Exploration of the cause-and-effect relations between intimate hygiene practices and AVM is needed, requiring intervention-based prospective studies. This would lead to evidence-based advice on intimate hygiene practices and AVM prevention, possibly increasing live birth rates. The unexpected high prevalence of douching in a Danish IVF population needs further exploration.

P-460 The Impact of Assisted Reproductive Technologies on Climate Change : The French Case

E. Saïs[1,2], M. Bendayan[1], I. Sellami[3], L. Alter[1], K. Fathallah[1], N. Swierkowski-Blanchard[1], C. Sonigo[3], F. Boitrelle[1], M. Grynberg[3]

[1]Poissy/St-Germain-En-Laye Hospital, Reproductive Medicine and Biology - Andrology - CECOS, Poissy, France
[2]BREED- INRAe- UVSQ- Paris Saclay University, Department of Biology-Reproduction- Epigenetic- Environment and Development, Jouy-En-Josas, France
[3]Antoine Béclère Hospital, Department of Reproductive Medicine & Fertility Preservation, Clamart, France

Study question: How much tons of carbon dioxide equivalent (tCO_2e) are generated by Assisted Reproductive Technologies in France in a year ?

Summary answer: It is estimated that Assisted Reproductive Technologies generated 55 691 tons of carbon dioxide equivalent in France in 2022.

What is known already: Since the 1800s, human activities have been the main driver of climate change, primarily due to burning fossil fuels (coal, oil and gas). Created in 1988, the Intergovernmental Panel on Climate Change (IPCC) provides regular assessments of the scientific basis of climate change, its impacts and future risks, and options for adaptation and mitigation. On December 12th 2015, 196 Parties adopted The Paris Agreement at COP 21 (Paris), a legally binding international treaty on climate change, aiming to limit global warming to well below 2 degrees Celsius. The French health sector is only beginning to measure it's carbon emission footprint.

Study design, size, duration: This study was conducted in Poissy/Saint-Germain-En-Laye Hospital during the year 2022 in the Department of reproductive medicine and biology. Greenhouse gas emissions were classified into three scopes. Scope 1 emissions are direct emissions divided into four categories : stationary combustion, mobile combustion, fugitive emissions, process emissions. Scope 2 emissions are indirect emissions from the generation of purchased energy. Scope 3 emissions are all indirect emissions, including both upstream and downstream emissions (separated into 15 categories).

Participants/materials, setting, methods: Every couple that required IVF or ICSI (including donors) during the year 2022 was included in this study. Number of personnel, transportation of patients, total medication prescribed, electricity consumption and medical furnitures were considered for the calculus of total emissions. Emission factors to calculate carbon emission were taken on the Ecological Transition Agency (ADEME) database. Extrapolation to all of France's ART clinics was possible using the BioMedical Agency (ABM) 2020 report on ART activities.

Main results and the role of chance: Assisted Reproductive Technologies generated 55 691 tons of carbon dioxide equivalent (tCO2e) in France in 2022 from 30 963 ICSI and 15 674 IVF procedures.

We estimate that every oocyte retrieval procedure generated 1.19 tCO2e (ICSI and IVF).

Department of Reproductive Medicine and Biology of Poissy/Saint-Germain-En-Laye (PSGEL) generated 796 tCO2e from 666 oocyte retrieval procedures (449 ICSI, 217 IVF), representing 1.43% of all IVF and ICSI in France.

Electricity consumption at PGSEL generated 1 051 tCO2e based on a total of 14 200 kw/h (average price of 0.1740 euros) in 2022.

Drugs prescriptions (758 069 euros) and Furniture (194 648 euros) at PGSEL generated respectively 409.584 tCO2e and 61.314 tCO2e in 2022 .

32 members of medical and non-medical at PGSEL staff generated 320 tCO2e in 2022.

Transportation of patients to PGSEL generated 4.44 tCO2e in 2022.

This is the first study to report an estimation of the carbon emission footprint of French ART.

Limitations, reasons for caution: Not all data was available (CO2 emissions created by the manufacture of active pharmaceutical ingredients in Asia) or taken into account (waste management, anesthesia type, hospital construction, etc).

Fertility preservation procedures were not considered in our calculations.

Results are therefore an under-estimation of real CO2 emissions.

Wider implications of the findings: French Healthcare was responsible for 46 MtCO2e (8% of national total) in 2021.

The biggest impact we can have in ART to lower our carbon footprint is optimise the pharmaceutical supply chain of drug manufacturing and use recycled materials for drug packaging (plastic, glass, aluminium, steel) as much as possible.

P-463 Data from 143,251 women indicates that black women access at-home fertility testing services later in life compared to white women in the United Kingdom

R. Relton[1], S. Rodrigues Vaz[1], N. Getreu[1,2], H. O'Neill[1,2], T. Vasavan[1]

[1]*Hertility Health, Research and Development, London, United Kingdom*
[2]*University College London, Institute for Women's Health, London, United Kingdom*

Study question: Does ethnicity play a role in fertility assessment-seeking behaviour of Black women in the United Kingdom (UK)?

Summary answer: Black women approach an at-home reproductive health and fertility assessment service later in their fertility journey than White women.

What is known already: Evidence from the Human Fertilisation and Embryology Authority (HFEA) shows that Black patients access fertility care two years later than the national average in the United Kingdom (UK) (36.4 vs 34.6 years).

Additionally, previous research has shown different prevalences of reproductive health conditions associated with infertility amongst Black women, such as fibroids and tubal occlusion. In combination with delayed access to fertility care, this may contribute to the lower live birth rates seen in Black patients in the UK.

Study design, size, duration: A retrospective observational study conducted on 143,251 Hertility Health users who completed a virtual health assessment between September 2020 and January 2023. The health assessment collected self-reported data on age, ethnicity, pre-existing diagnoses of reproductive health conditions, whether they were actively trying to conceive (TTC) and the length of time they had been actively TTC.

Participants/materials, setting, methods: A total of 25.9% users (n = 37,170) indicated they were TTC. The majority of those TTC self-identified as White (82.9%), followed by Asian (7.4%), Mixed (3.6%), Black (4.6%) and 'Other' (1.5%). Summary statistics (mean ± SD and %) regarding age and prevalence of pre-existing conditions of users TTC have been reported. Additional statistical analysis of the associations of time spent TTC between ethnicities was conducted via Chi-squared test ($\chi 2$); p values <0.05 were considered significant.

Main results and the role of chance: A significant relationship was observed between time spent TTC and ethnicity; the strongest association was observed between Black and White users $\chi 2$ (16, n = 34,706)=120, $p < 0.0001$). Comparison of time spent TTC, and average age showed that fewer Black women undertook the virtual health assessment at < 6 months of TTC than White women (29.3%, n = 469 vs 34.1%, n = 9820) at a moderately older age (31.3 ± 6.5 years vs 29.8 ± 5.7 years).

A higher percentage of Black women were TTC for >5 years compared to White women (14.2%, n = 227 vs 8.8%, n = 2544). Additionally, Black women at this time point were approximately four years older than White women (36.9 years ± 6.0 years vs 33.0 ± 5.1 years).

Secondary analysis of the prevalence of reproductive health conditions associated with infertility indicated that 20.1% (n = 133) and 22.5% (n = 149) of Black women had a preexisting condition at < 6 months and >5 years of TTC, respectively, vs 22.6% (n = 1363) and 19.2% (n = 1158) of White women in the corresponding TTC length groups.

Limitations, reasons for caution: As the virtual health assessment data was self-reported, there is a risk of recall bias and false reporting. Data was stratified via the main ethnicities and did not take the heterogeneity within ethnic groups or mixed ethnicities into account.

Wider implications of the findings: This data suggests that Black women approach fertility testing services later than White women, which may contribute to the disparities between pregnancy outcomes in the UK and cannot fully be accounted for by preexisting diagnoses associated with infertility. Further investigations are needed to outline the underlying reasons for this.

P-465 Effect of male age on the outcome of frozen embryo trnasfer cycle in women over 40 years

S.Y. Shin[1], H.S. Koo[1], J.H. Kim[1], J.H. Kim[1], H. Kwon[1], C. Park[1], D.H. Choi[1], J.E. Shin[1]

[1]*CHA hospital, Infertility center, Seongnam-si- Gyeonggi-do, Korea- South*

Study question: Does male age affect the outcome of in vitro fertilization in women over 40?

Summary answer: Advanced male partner's age is associated with decreased pregnancy rate, implantation rate and ongoing pregnancy/live birth rate.

What is known already: Fertility is known to have the greatest correlation with female age. Older women have a relatively lower pregnancy rate and higher miscarriage rate. It is also widely known that male partner's age is associated to pregnancy rate with increased sperm DNA fragmentation and decreased sperm motility. Age of marriage is delayed both male and female partners, assisted reproductive techniques are often conducted in women over 40 years. The effect of male age on IVF/ICSI outcomes on women over 40 is poorly explored.

Study design, size, duration: This is a retrospective cohort study analysed 1046 cycles of couples with an age of 40 or more of female partners and their male partners, performed at a single IVF center of university hospital between 2019 and 2022. The primary outcome was ongoing live birth and secondary outcomes were clinical pregnancy and miscarriage.

Participants/materials, setting, methods: Couples of primary/secondary infertility with female partner age over 40 years who underwent frozen-embryo transfer cycles were selected. couples who collected their sperm from TESE/TESA were excluded.

Main results and the role of chance: We decided the male partner's age in three groups, age less than 40, 41-45, and age over 45. There was a negative effect of male age on ongoing live birth and clinical pregnancy rate.(20.0%, 10.3%, 10.9%, $p < 0.001$, 33.7%, 28.4%, 19.9%, $p = 0.017$). And we sub-analyzed ongoing live birth rate and clinical pregnancy rate into female age group(female age of 40, 41-42, and over 43). The ongoing pregnancy/live birth rate and clinical pregnancy rate were negatively associated with male partner's age especially in female age group of over 43 years.

Limitations, reasons for caution: This study is limited to the information on confounding factors. The study may also be limited due to its selection criteria.

Wider implications of the findings: This study provides information regarding IVF/ICSI outcomes on women over 40 years of age

[7]Institut d'Investigació Biomèdica de Bellvitge IDIBELL, Barcelona Stem Cell Bank, Barcelona, Spain

Study question: To classify embryos according to their metabolic fingerprint with a robust, non-invasive methodology

Summary answer: Our Hyperspectral (HS) phasor analysis coupled to artificial intelligence simultaneously detects 6+ metabolites to profile and classify competent embryos and oocytes safely and consistently.

What is known already: Metabolism plays a key role in oocyte and embryo developmental competence. However, current methods to measure oocyte and embryo metabolism are either invasive, phototoxic, too slow or based on indirect analysis in cumulus cells or culture media. Some intracellular metabolites are autofluorescent and their concentration can be quantified using HS imaging when using the correct light excitation. HS imaging is an optical technique whereby the full emission spectrum is obtained for each pixel of an image. Thus, raw HS data encodes rich metabolic information of an imaged cell as numerous metabolites are excited simultaneously.

Study design, size, duration: A total of 96 mouse embryos and 115 oocytes were analyzed. *In vivo* fertilized embryo cohorts included control, glucose-starved, pyruvate/lactate-starved, and glucose/pyruvate/lactate-starved. Oocyte cohorts included oocytes obtained from young female mice analyzed blindly either immediately after collection or after overnight culture (*in vitro* aged), and from old female mice. After HS analysis, oocytes were inseminated by ICSI and cultured *in vitro* to correlate their potential to develop up to blastocyst with their metabolic profiles.

Participants/materials, setting, methods: Samples were imaged using multiphoton illumination near the infra-red to avoid phototoxicity. The HS detection covered the whole visible spectrum allowing simultaneous measurement of 6+ relevant metabolites for the embryo/oocyte biology: NADH (free and bound), FAD^{+}, retinol, retinoic acid, and flavins among others. Afterwards, we applied dimensionality reduction (2D phasor image) from which machine learning algorithms learned to classify the different samples. We used Akaike Information Criterion (AIC) model. Cross validation was performed using 80%/20%.

Main results and the role of chance: The Area Under the ROC Curve (AUC) achieved by binary classification as well as the average class-accuracy (computed as the average of the confusion matrix diagonal) were calculated in four-class classification in the case of embryos. [EM1] Brightfield images of the test set of embryos were evaluated by 4 embryologists to look for compromised embryos. Human graders reached an AUC of 51% of the samples using brightfield compared to 93.7% of the AI algorithm using HS-Phasor. A similar approach using the HS-Phasor was conducted on the different cohorts of mouse oocytes. It was able to separate the oocyte classes with an average AUC of 96.2% and make a statistical correlation with their blastulation efficiency with a 82.2% AUC. The viability of embryos and oocytes after imaging was comparable to that of non-imaged controls, indicating that the imaging procedure had no effect on the posterior *in vitro* development of the embryos.

Limitations, reasons for caution: The cohort size is limited although statistically robust. Blastulation efficiency will need to be complemented (ongoing work) with implantation measurements.

Wider implications of the findings: The HS-phasor method has the potential to become a paradigm shift in IVF embryo selection due to the reliable, non-invasive direct measurement of the oocyte/embryo physiology. The adaptation into clinical practice can be straightforward as it offers an additional layer of information for oocyte/embryo assessment without compromising time nor viability.

Trial registration number: NA

O-238 Artificial intelligence algorithms in assisted reproduction: differences in the evaluation of embryos from fresh or vitrified donor oocytes

L. Murria[1], M. Meseguer[2], A. Coello[2], P. Campos[2], L. Bori[1], A. Cobo[2]

[1]IVI Foundation- Health Research Institute La Fe- IVIRMA Valencia, Research and Innovation, Valencia, Spain
[2]IVIRMA Valencia, IVF Laboratory, Valencia, Spain

Study question: Do the Embryoscope and EmbryoscopePlus systems' built-in software evaluate differently embryos from vitrified or fresh oocytes?

Summary answer: The embryo scores provided by artificial intelligence (AI) algorithms are lower for embryos originated from vitrified/warmed oocytes than for those that come from fresh oocytes.

What is known already: Time-lapse technology has enabled embryologists to develop several AI-based tools that allow the automation and standardization of embryo quality assessment. EmbryoScope and EmbryoScopePlus systems include deep learning-based models using only time-lapse image sequences (iDAScore v1.0 and v.2.0) and the machine learning-based model (KIDScore D5 v3) which classifies embryos in categories based on cleavage time points and blastocyst appearance. It has been reported that fertilization, pregnancy and implantation rates in vitrified oocytes are comparable to those of fresh oocytes. To our knowledge, this is the first study to test whether artificial intelligence tools assess embryos derived from these oocytes differently.

Study design, size, duration: This retrospective study includes the analysis of 34950 videos of embryos from fresh and vitrified donor oocytes. Embryos were cultured on EmbryoScope and EmbryoScopePlus Time Lapse systems and morphological and morphokinetic parameters were automatically detected by EmbryoViewer software. Senior embryologists routinely evaluated the embryos according to the ASEBIR criteria. In addition, embryos were graded using IDAScore v1, IDAScore v2 and KIDScoreD5 algorithms in different scores from low to high quality (1-9.9).

Participants/materials, setting, methods: The scores of embryos from fresh or vitrified donor oocytes obtained with the different algorithms were compared. Specifically, 21533 embryos from fresh and 12710 from vitrified oocytes with the IDAScore v1; 21335 from fresh and 12705 from vitrified with the IDAScore v2; and 13544 from fresh and 6559 from vitrified with the KIDScore v3. In addition, the ASEBIR evaluation performed by embryologists was also compared between embryos from fresh (21968) and vitrified oocytes (12980).

Main results and the role of chance: Mean scores of embryos coming from fresh oocytes from IDAScore v1, IDAScore v2 and KIDScore v3 were 5.34 ± 2.91, 3.48 ± 2.93, 5.13 ± 2.1 respectively. And mean scores of those from vitrified oocytes were 5.09 ± 2.83, 3.1 ± 2.71, 4.99 ± 2.01. Thus, mean embryo scores obtained by the 3 artificial intelligence algorithms were significantly higher* for embryos from fresh oocytes compared to those from vitrified oocytes. However, this lower embryo assessment of those from vitrified oocytes was not detected when comparing embryo quality according

to ASEBIR classification. We hypothesized that it might be because several embryos that had not reached blastocyst stage on D6 were included in this comparison. Comparisons were repeated excluding these embryos, mean scores of embryos from fresh oocytes from IDAScore v1, IDAScore v2 and KIDScore v3 were 7.31 ± 2.12, 5.15 ± 2.79, 5.18 ± 2.07 respectively. Mean scores of those from vitrified oocytes were 7.14 ± 2.12, 4.75 ± 2.70, 5.01 ± 2.01. Again, mean scores of embryos from fresh oocytes were significantly higher* than those from vitrified oocytes. In this analysis, this significant difference* in embryo score was also detected according to the ASEBIR classification.

*p<.05

Limitations, reasons for caution: This project is limited by its retrospective and single-center nature. A multicenter study could be performed to determine whether these minimal but significant differences in the evaluation of embryos from fresh or warmed oocytes have any impact on clinical outcome.

Wider implications of the findings: This study shows that embryos from vitrified oocytes have significantly lower scores than those from fresh oocytes. The embryo assessment performed in this study is based on AI models that allow their instantaneous, non-invasive, accurate and objective evaluation. Thus, the impact of these differences on clinical outcome, should be analyzed.

Trial registration number: not applicable

O-239 A model based on artificial intelligence for the non-invasive prediction of embryo aneuploidy

A. Polia[1], K. Anagnostara[1], M. Belmpa[1], P. Giannelou[1], T. Karagianni[1], I. Mastromina[1], D. Nikiforaki[1], A. Sialakouma[1], E. Tsorva[1], S. Davies[1], I. Sfontouris[1]

[1]Hygeia IVF Embryogenesis, IVF Laboratory, Athens, Greece

Study question: Can the automated artificial intelligence (AI) model iDAScore predict embryo aneuploidy?

Summary answer: The AUC for aneuploidy prediction of iDAScore was AUC 0.640, with optimal cut-off score 7.75, sensitivity 61.0% and specificity 60.9%.

What is known already: Embryo morphokinetics and image analysis using AI have been proposed as alternative approaches for non-invasive embryo aneuploidy prediction. The automated AI model iDAScore, as well as the morphokinetic embryo selection model KIDScoreD5 have been shown to have correlation with embryo ploidy status. The aim was to study the performance of aneuploidy prediction using the iDAScore, KIDScoreD5 and morphology grading (Gardner criteria).

Study design, size, duration: Retrospective study including 382 blastocysts of known ploidy from 92 patients undergoing PGT-A in a single centre during January-December 2022. For statistical analysis, continuous and categorical data were compared using ANOVA and Fisher's exact test/Chi-square, respectively. ROC analysis was used to estimate the discrimination performance of variables to predict aneuploidy. Stepwise logistic regression was used to identify confounding variables and construct a model for aneuploidy prediction.

Participants/materials, setting, methods: Embryos were cultured in Embryoscope, underwent laser assisted hatching on Day3, were biopsied on Day5-Day6 and were vitrified. Whole-genome amplification and next-generation sequencing were used for PGT-A. iDAScore values were calculated using v1.2.0. KIDScoreD5 v.3 was calculated after annotation of the required morphokinetic parameters in Embryoviewer. For Gardner criteria, inner cell mass (ICM) and trophectoderm (TE) were classified into grades A to C. The expansion in all biopsied blastocysts was > =grade 4.

Main results and the role of chance: Out of 382 embryos analysed, 127 (33.2%) were euploid and 255 (66.8%) were aneuploid. Euploid embryos were associated with significantly higher iDAScore (7.69, 95% CI 7.44-7.95 vs 6.86, 95% CI 6.66-7.09, $p < 0.001$), higher KIDScoreD5 (6.41, 95% CI 6.07-6.75 vs 5.74, 95% CI 5.51-5.97, $p = 0.001$) and lower maternal age (37.10 years, 95% 36.39-37.82 vs 39.83 years, 95% CI 39.36-40.30, $p < 0.001$) compared to aneuploid embryos. Significantly more embryos with grade A ICM (A:39.4%, B:26.0%, C:20.0%, $p = 0.013$) and grade A TE (A: 45.9%, B:29.6%, C:23.6%, $p = 0.002$) were euploid compared with B and C grades, respectively. Blastocysts biopsied on Day 5 and Day 6 had similar proportions of euploidy (34.9% vs 27.6%, $p = 0.125$). The AUCs for aneuploidy prediction were: iDAScore: 0.640 (95% CI 0.582-0.699), KIDScoreD5: 0.604 (95% CI 0.542-0.665), ICM grade: 0.581 (95% CI 0.521-0.640), TE grade: 0.596 (0.536-0.657), maternal age: 0.694 (0.640-0.748). The optimal cut-off (Youdex index) for aneuploidy prediction of iDAScore was 7.75 (sensitivity 61.0%, specificity 60.9%). Following stepwise multivariate logistic regression, the variables that entered the model were iDAScore, maternal age and TE grade. The model iDAScore+age+TE grade increased the ability of aneuploidy prediction (AUC 0.747, 95% CI 0.696-0.796). KIDScoreD5, ICM grade and day of biopsy failed to enter the model.

Limitations, reasons for caution: This is a retrospective study and therefore the presence of bias cannot be excluded. iDAScore and KIDScore are models originally developed for the prediction of implantation and not for the diagnosis of embryo aneuploidy.

Wider implications of the findings: iDAScore appears to associate with embryo aneuploidy. Combination of iDAScore+age+TE increased the AUC for aneuploidy prediction. iDAScore can used as a decision-support tool for prioritising embryos for transfer, cryopreservation or biopsy. The analysis of more embryos is needed to confirm the present findings.

O-240 Does embryo categorisation by existing artificial intelligence, morphokinetic, or morphological embryo selection models correlate with blastocyst euploidy rates?

K. Kato[1], S. Ueno[2], J. Berntsen[3], T. Okimura[2], T. Kuroda[1]

[1]Kato Ladies Clinic, Gynecology, Tokyo, Japan
[2]Kato Ladies Clinic, IVF Laboratory, Tokyo, Japan
[3]Vitrolife A/S, Data Science, Arhus, Denmark

Study question: Does embryo categorization by existing artificial intelligence, morphokinetic, or morphological embryo selection models correlate with blastocyst euploidy?

Summary answer: Our results show that existing blastocyst scoring models correlate with ploidy status.

What is known already: A previous study suggested that morphokinetic parameters should not be used yet as a surrogate for PGT-A to determine embryo ploidy in vitro. As for predicting pregnancy likelihood, AI models have been proposed for predicting ploidy status. Discrimination performance in terms of AUC has been reported of up to 0.80 when including metadata such as maternal age, and 0.63 when AI predictions were made based on time-lapse images alone. However, as the studies only looked at models trained for ploidy prediction, it is unclear how existing blastocyst scoring systems would perform at discriminating euploids and aneuploids.

Study design, size, duration: A total of 834 patients, 3,573 blastocysts were retrospectively analyzed. The cycles were stratified into five maternal age groups according to the Society for Assisted Reproductive Technology (SART) age groups (< 35, 35–37, 38–40, 41–42, and >42 years). The quality and scoring of embryos were assessed by iDAScore v1.0 (iDA, Vitrolife, Sweden), KIDScoreTM D5 v3 (KS; Vitrolife), and Gardner grading (GG).

Participants/materials, setting, methods: Embryos were cultured in the EmbryoScope+ and EmbryoScopeFlex (Vitrolife). iDA was automatically calculated using the iDAScore model running on the EmbryoViewer (Vitrolife). KS was calculated in EmbryoViewer after annotation of the required parameters. ICM and TE were annotated according to the Gardner grading. The degree of expansion in all blastocysts was Grade 4 due to our freezing policy. Furthermore, Gardner's scores were stratified into four grades (A: AA, B: AB BA, C: BB, D: others).

Main results and the role of chance: At first, the correlation between all assessment methods and euploid rates were analyzed using a trend-test. Euploidy rates significantly correlated with iDA in each age group ($p = 0.035$ for age <35 years, $p < 0.001$ for all other age groups) and decreased

progressively with increasing maternal age in each score group. Furthermore, euploidy rates were significantly correlated with KS ($P < 0.0001$), except in the youngest age group ($p = 0.07$). They decreased progressively with increasing maternal age in each score group. Similarly, euploidy rates were significantly correlated with GG ($P < 0.0001$), except in the youngest age group ($p = 0.06$). They decreased progressively with increasing maternal age in each score group. Secondly, the performance of the euploidy prediction for each embryo scoring model was compared using the area under the curve (AUC) of the receiver operating characteristic curve. The AUCs for euploid prediction of iDA, KS, and GG for all ages were 0.666, 0.655, and 0.642, respectively. iDA and KS were significantly higher than Gardner grading (iDA vs. GG: $p = 0.004$; KS vs. GG: $p = 0.02$). Additionally, there was no significant difference between iDA and KS.

Limitations, reasons for caution: It was based on minimal stimulation and the use of natural cycle for IVF treatment, which involved only insemination by ICSI. Furthermore, the blastocyst assessment models that we tested were initially developed for pregnancy prediction and not for the prediction of the chromosomal status of an embryo.

Wider implications of the findings: Existing blastocyst assessment models that reflect blastocyst viability in view of implantation potential to some extent correspond with ploidy status. Therefore, existing blastocyst scoring models can be used to support the decision for embryo biopsy and/or to reduce the patient's cost by deciding on which embryo(s) to biopsy.

O-241 Association of a deep learning-based scoring system with morphokinetics and morphological alterations in human embryos

T. Takahashi[1], K. Ezoe[2], K. Shimazaki[1], T. Miki[2], Y. Tanimura[1], A. Amagai[1], A. Sawado[1], H. Akaike[1], M. Mogi[1], S. Kaneko[1], M. Kato[1], T. Okimura[1], K. Kato[3]

[1]Kato Ladies Clinic, IVF Laboratory, Tokyo, Japan
[2]Kato Ladies Clinic, R&D Division, Tokyo, Japan
[3]Kato Ladies Clinic, Gynecology, Tokyo, Japan

Study question: How is the deep learning-based scoring system, iDAScore, associated with biological events during the pre-implantation period?

Summary answer: The morphokinetic analysis revealed that during the transformation to blastocyst stage, morphokinetic and morphological events were strongly associated with iDAScore.

What is known already: A recent study reported that the commercially available deep learning model for automatic scoring, iDAScore, performed as well as, or even better than, the more traditional embryo assessment-based model on blastocyst morphology or annotation-dependent ranking tools. Furthermore, a correlation between iDAScore and the incidence of rapid cleavage, time duration until the blastocyst stage, and morphological grade of the inner cell mass and trophectoderm was reported. However, the association of iDAScore with other key morphokinetic parameters remains undetermined.

Study design, size, duration: This retrospective observational study included 925 patients who underwent oocyte retrieval in a clomiphene citrate-based minimal stimulation cycle and obtained expanded blastocysts in ICSI cycles between October 2019 and December 2020. Oocytes of patients with different diagnoses of infertility were included in the analysis, while cases involving cryopreserved gametes or surgically retrieved sperm were excluded. The association of iDAScore with morphokinetics and morphological alteration during fertilisation, cleavage stage, compaction, and blastocyst stage were analysed.

Participants/materials, setting, methods: Microinjected oocytes were assessed using a time-lapse monitoring (TLM) culture system (Embryoscope). Oocytes not suitable for TLM assessment, due to excess of residual corona cells or inadequate orientation for correct observation, were not analysed. Phenomena, relevant to meiotic resumption, pronuclear dynamics, cytoplasmic/cortical modifications, cleavage pattern, and embryo quality, were annotated. Multiple linear regression analysis was used to assess the relative importance of the possible predictor variables in explaining the iDAScore.

Main results and the role of chance: The duration of the cytoplasmic halo was significantly prolonged in the low scoring blastocysts. The timing of female and male pronuclei breakdown was significantly delayed in the low scoring blastocysts compared with the high scoring blastocysts. Embryos with either trichotomous, multi-chotomous, rapid, or reverse cleavage or asymmetric division exhibited a lower score than embryos with normal cleavage. The cell number and amount of blastomere fragmentation on days 2 and 3 were significantly associated with iDAScore. Delayed division, compaction, blastulation, and blastocyst expansion were observed in the low scoring embryos. The incidence of blastomere exclusion and extrusion during embryonic compaction was significantly higher in low scoring embryos than in high scoring embryos. Blastocyst morphology was significantly associated with iDAScore. Multiple linear regression analysis revealed that morphokinetic and morphological events were strongly associated with iDAScore especially during the transformation to blastocyst stage, which has been considered important in embryo assessment. It was also revealed that some morphological parameters and time durations during the cleavage stage were also correlated with the iDAScore.

Limitations, reasons for caution: The study data derive from treatments carried out in a single centre. The study findings therefore require independent verification from other research groups.

Wider implications of the findings: We found that iDAScore was significantly correlated with morphokinetics and morphological alterations of pre-implantation embryos, especially during the late pre-implantation period. Our findings may contribute to the literature on deep learning model-based embryo selection, which may provide patients with a compelling explanation regarding blastocyst selection.

O-242 Comparing the performance of an artificial intelligence model for predicting embryo implantation between clinics with patient cohorts of different maternal age distributions

M. Johansen[1], K. Kato[2], S. Ueno[3], S. Palm[4], M. Kernbach[4], B. Basak[5], I. Keles[6], A.V. Gabrielsen[7], L.H. Iversen[7], J. Berntsen[1]

[4]MVZ PAN Institut, PAN Klinik am Neumarkt, Cologne, Germany
[5]American Hospital, In-Vitro Fertilization Laboratory, Istanbul, Turkey
[6]Koc University Hospital, Department of Women's Health and IVF, Istanbul, Turkey
[7]Regionshospitalet Horsens, Fertilitetsklinikken, Horsens, Denmark

Study question: Do differences in maternal age distributions contribute to the variability in the discrimination performance of an embryo viability model based on artificial intelligence (AI)?

Summary answer: Using a common reference age distribution, enables a less biased and thus more standardized comparison of embryo implantation prediction between clinics.

What is known already: Studies from different clinics have shown a quite large variation in the performance of the same AI model. The most common method of comparing performance between clinics is to use simple clinic-specific performance statistics while ignoring dissimilarities between clinics in patient cohorts, culture conditions etc. A more appropriate method is meta-analysis of performance across clinics rather than using overall performance, however, this does also not account for dissimilarities between clinics. Assessing the performance in subgroups, although common practice, reduces the sample size significantly and limits interpretation to each separate subgroup.

Study design, size, duration: This is a retrospective observational multi-site study with data from four clinics collected over varying time periods. In all participating clinics embryos were cultured in EmbryoScope time-lapse incubators (ES-D, ES+, ES-Flex; Vitrolife). Embryo implantation likelihood was

evaluated with the iDAScore v1.0 AI decision support tool. Data from 4,805 single embryo transfers on day 5 and 6 (fresh and frozen) with known fetal heartbeat outcome were included. Donor egg cycles were strictly excluded.

Participants/materials, setting, methods: Performance of embryo implantation prediction was measured in terms of areas under the ROC curve (AUC). To account for age differences, we performed a standardization of the AUCs using a weighted version of the ROC curves with weights defined as the ratio between the age densities in a reference population and in the specific clinic. The reference population was comprised of data that was held out from the original model development.

Main results and the role of chance: Different age distributions with medians ranging from 32 to 40 years were observed in the four clinics. The unweighted overall AUC was 0.65 (95% CI: 0.64 to 0.69), whereas the AUC in the reference population was 0.67 (95% CI: 0.63 to 0.71). The predictive performance of the iDAScore model varied between clinics with the unweighted AUCs ranging from 0.58 to 0.69. Meta-analysis across all four clinics showed a summary average of 0.65 (95% CI: 0.59 to 0.70).

We then standardized to the age distribution in a reference population in which the maternal age ranged from 21 to 44 years with a median of 38. The values of the AUCs after standardization ranged from 0.60 to 0.71 between clinics with a summary average of 0.67 (95% CI: 0.62 to 0.72). The standard error of the summary average was 5% lower when standardization was used and the estimated variation between clinics in the meta-analysis was 16% lower.

In conclusion, we have shown with our standardized analysis method that the variability in embryo performance prediction between clinics can be partially explained by the difference in maternal age distributions.

Limitations, reasons for caution: The summary average of the AUC is highly dependent on the age distribution in the chosen reference population. Therefore, the exact value of this estimate should be interpreted with caution. However, comparing AUCs between clinics using this standardization approach is less biased by differences in age distribution.

Wider implications of the findings: Simple comparisons of the performance of AI-based embryo implantation prediction in different clinics may be influenced by factors such as age. Using a standardization approach, this influence can be mitigated, enabling a less biased comparison. Differences in other important factors apart from age can potentially also be considered.

O-243 Personalized pregnancy odds estimation can be obtained using AI embryo evaluation and individual patient characteristics

D. Seidman[1,2], R. Maor[1], Y. Tauber[1], Y. Amar[1], D. Gilboa[1]

[1]*AIVF, Aivf, Tel Aviv, Israel*
[2]*Tel Aviv University, Sackler School of Medicine, Tel Aviv, Israel*

Study question: Can EMA™ (AIVF, Israel) artificial intelligence (AI) platform provide personalized success estimates based on the patient's metadata and embryonic development?

Summary answer: Individual patients can be given an accurate estimation of their chances for a clinical pregnancy using AI-based embryo evaluation and patient metadata.

What is known already: AI models for embryo evaluation are trained on diverse datasets using data from multiple clinics and from patients with varying ages and clinical history. Precision medicine can be attained by AI models that provide individual patients with personalized success rates per embryo transfer based on their characteristics.

Study design, size, duration: A large dataset (9,812 embryos) from 3 geographically diverse IVF Clinics (Israel, Spain, USA) with known clinical pregnancy (fetal heartbeat) and patient characteristics obtained from Electronic Medical Records (EMR) were used to evaluate the importance of individual features contributing to pregnancy.

Participants/materials, setting, methods: Machine learning models were trained to predict clinical pregnancy on a large training and feature set which combines AI scores (EMA™, AIVF) with additional information obtained from EMR systems and intrinsic features that can be derived from the embryo cohort. The importance of each one of the features for the prediction ability of the models was evaluated.

Main results and the role of chance: AI embryo score, maternal age and cohort features were found to be the major contributing factors for the prediction models, thus improving the accuracy of the estimates for pregnancy probability. Significant contributing factors were: cohort size, number of viable embryos, patient age, number of past treatments, BMI and EMA score. The AUC of the AI embryo score model was 0.7, when factoring in the patient metadata and the cohort features, the AUC of the combined model was 0.75.

Limitations, reasons for caution: This study is limited by its retrospective design. A prospective study is needed to validate the results.

Wider implications of the findings: This study validates the use of AI-based scores for embryo evaluation, for relative grading of the embryos within the cohort, and also to estimate the true pregnancy odds of each embryo based on individual patient features. This can provide a superior decision support tool for doctors, embryologists, and patients.

O-244 Mitochondrial fission factor (MFF) is required for female fertility and oocyte development

R. Hua[1], Z. Hai[1], J. Gu[1], C. Guo[1], Y. Xiao[1], P. Zhao[1], J. Su[1], W.S.B. Yeung[1], T. Wang[1]

[1]*The University of Hong Kong-Shenzhen Hospital, Reproductive Medicine Center, Shenzhen, China*

Study question: To explore the role of Mitochondrial fission factor (MFF) in female fertility and oocyte development using a *Mff* knockout mouse model.

Summary answer: *Mff* deficiency influences mitochondrial dynamics in oocytes at germinal vesicle stage (GV), and results in premature ovarian failure (POF) and female infertility.

What is known already: *Mff* regulates mitochondrial quality control (MQC) by influencing mitochondrial dynamics. MQC has critical effects on oocyte development and POF. However, little is known about the role of *Mff* in oocyte development and female fertility.

Study design, size, duration: The *Mff* knockout ($Mff^{-/-}$) mice were generated via the CRISPR-Cas9 system. Adult $Mff^{-/-}$ female mice were compared to wildtype (WT) female mice. Female mice at 2-month old from each group ($Mff^{-/-}$ or WT, n = 5) were used to assess the fecundity for 10 months. The follicle development (n = 4 mice), the number of GV oocytes (n = 5 mice) and metaphase II (MII) oocytes (n = 5 mice) were determined.

Participants/materials, setting, methods: Female mice from each group were mated with adult WT males to assess the fecundity. Follicle development was evaluated in ovaries after fixation, paraffin embedding, and sectioning, followed by hematoxylin and eosin staining. MFF and DRP1 protein expression was evaluated by western blot. Oocyte mitochondria were stained with the Mito-Tracker Red CMXRos.

Main results and the role of chance: The *Mff* deficient ovaries had significantly lower levels of MFF (0.056 vs. 1, $p < 0.01$) than the WT ovaries. $Mff^{-/-}$ female mice were infertile (0 vs. 39, $p < 0.05$). Mature (8-week-old) *Mff* deficient ovaries had significantly lower weight (0.0043 vs. 0.011, $p < 0.05$) compared to the WT. The 2-month-old female $Mff^{-/-}$ mice had a lower number of primordial (220 vs. 775, $p< 0.05$), primary (128 vs. 580, $p< 0.05$),

secondary (29 vs. 82, $p< 0.05$) and antral follicles (5 vs. 23, $p< 0.05$). The numbers of GV oocytes (18 vs. 37, $p< 0.05$) and MII oocytes (2 vs. 16, $p< 0.001$) were lower in the *Mff*$^{-/-}$ mice than the WT mice. In addition, the *Mff*$^{-/-}$ ovaries expressed significantly less mitochondrial fission key regulator DRP1 (0.54 vs. 1, $p< 0.05$). *Mff*$^{-/-}$ oocytes contained elongated and aggregated mitochondria compared to the discrete and evenly distributed mitochondria in the ooplasm of WT oocytes. Herein, we found that the *Mff* played a concerted role in oocyte and follicle development.

Limitations, reasons for caution: The present observations in mice may not be applicable to humans. The results are derived global knockout of *Mff*. It is not known which kind of cell plays a vital role in fertility. Further investigation is needed to explore the regulatory mechanism of *Mff* in oocyte development and fertility regulation.

Wider implications of the findings: This study provides important insights into the relationship between mitochondrial dynamics and female fertility.

O-245 Monitoring oxytocin release in vivo during female sexual behavior using a genetically encoded sensor

P. Wang[1]

[1]*Beijing Chao-Yang Hospital Affiliated to Capital Medical University, Department for Human Reproduction, Beijing, China*

Study question: To investigate if the release of oxytocin (OT) in the medial prefrontal cortex (mPFC) fluctuates during discrete phases of female sexual behavior.

Summary answer: Using a highly sensitive OT-specific genetically encoded sensor, we have recorded behavioral phase-specific OT release in mPFC in freely moving mice.

What is known already: OT has been reported to participate in the regulation of sexual behavior of both male and female mice. OT activated mPFC neurons by increasing their firing activity. Loss of function studies indicated that pharmacological or genetic ablation of OT signaling in mPFC largely disrupts female sociosexual interest in male mice. OT action is indispensable in female sociosexual behavior, however, its release dynamics have never been recorded before due to technical difficulties. We have developed a highly sensitive OT-specific G-protein-coupled receptor activation-based sensor (OT1.0), and recorded intracellular OT release in behaving mice on the millisecond time-scale.

Study design, size, duration: Eight C57BJ/6N mice were divided into two groups (n = 4 per group). Intracellular viral transduction with OT1.0 or OT1.0mut vectors was administrated to each group. After viral transduction, 3 weeks were waited to allow sufficient viral expression.

Participants/materials, setting, methods: After anesthetization, AAVs encoding hSyn-OT1.0 or hSyn-OT1.0mut were injected into the left mPFC of adult female wild-type C57BJ/6N mice; Optical fibers were implanted into the mPFC 3 weeks after AAV injection. The animal's sexual behaviors were recorded and annotated, while a fiber photometry system was used to record fluorescence signals in the mPFC, using a 470-nm laser at 50 μW for OT1.0 or OTmut.

Main results and the role of chance: To investigate the dynamics of OT release in mPFC during female sexual behavior, we recorded OT1.0 fluorescence in behaving female mice using fiber photometry. In mPFC of female mice, increases in OT1.0 fluorescence were first observed during the sniffing stage (with rise and decay time constants (T1/2) of 0.4 s and 1.4 s, respectively). After ejaculation of male mice, mPFC OT1.0 signals of the female mice increased significantly with rise and decay time constants (T1/2) of 0.5 s and 1.5 s, respectively. As a negative control, fluctuation of fluorescence was not observed during any phase of sexual behavior in mice expressing OT1.0mut, suggesting the specificity of the signals measured in mice expressing OT1.0.

Limitations, reasons for caution: The OT dynamics in mPCF during female sexual behaviors are only recorded in mice. Clinical trials and imaging studies are required to substantiate the therapeutic role of OT in human subjects.

Wider implications of the findings: This study is likely to deepen our understanding of the role of OT in modulating female sociosexual behavior, which provides more evidence suggesting OT's potential therapeutic potential in treating sexual dysfunctions.

Abstract citation ID: dead093.300
O-246 The molecular mechanism of miR-96-5p in the pathogenesis and treatment of polycystic ovary syndrome

X. Li[1]

[1]*China Agricultural University, State Key Laboratory of Biotechnology, Beijing, China*

Study question: Polycystic ovary syndrome, characterized by the androgen excess and arrest of antral follicles, is lacking novel specific diagnostic biomarkers and therapeutic targets.

Summary answer: Study of the molecular mechanisms of microRNAs in the etiology and its potential applications in PCOS provides the insight.

What is known already: Some of molecular mechanisms of microRNAs have been demonstrated involved in the etiology of PCOS

Study design, size, duration: Clinically, we collected the samples of serum, follicular fluid (FF) and primary human granulosa cells (hGCs) of PCOS patients (n = 70) vs. non-PCOS women (n = 60). Experimentally, we carried out studies with 3-types of induced PCOS-like mice.

Participants/materials, setting, methods: By analysing the expression levels of miR-96-5p in serum, follicular fluid (FF) and primary human granulosa cells (hGCs) of PCOS patients (n = 70) vs. non-PCOS women (n = 60). as well as in ovaries from 3-types of induced PCOS-like mice.

Main results and the role of chance: Clinically, we demonstrated that the elevated circulating miR-96-5p levels were significantly correlated with the PCOS disordered endocrine clinical features, and the area under the curve of receiver operating characteristic was 0.8344, with 75.71% specificity and 80% sensitivity. Mechanically, we identified miR-96-5p as an androgen-regulated miRNA that directly targets the forkhead transcription factor FOXO1. Inhibition of miR-96-5p decreased estrogen synthesis, while decreasing the cell proliferation index of KGN via regulating the expression of FOXO1 and its downstream genes. Inversely, inhibition of FOXO1 abrogated the effect of miR-96-5p on estrogen synthesis and proliferation index. Of note, ovarian intra-bursal injection of miR-96-5p agomir rescued the phenotypes of dehydroepiandrosterone-induced PCOS like mice.

Limitations, reasons for caution: This study needs a large-scale clinical investigation to confirm the specificity and sensitivity of miR-96-5p as a clinical biomaker.

Wider implications of the findings: In conclusion, our results clarified a vital role of miR-96-5p in the pathogenesis of PCOS and might serve as a novel diagnostic biomarker and therapeutic target for PCOS.

O-247 The intrafollicular inflammatory response during ovulation in women is most likely controlled by high concentrations of active cortisol being synthesized shortly before follicular rupture

M. Johannsen[1], **L.L.C. Poulsen**[1], **L.S. Mamsen**[1], **M.L. Groendahl**[2], **A.L. Egelund**[3], **N.L. Lauritsen**[4], **E.C. Carstensen**[4], **B. Styrishave**[4], **C.Y. Andersen**[1]

[1]*Copenhagen University Hospital, Laboratory of Reproductive Biology, Copenhagen, Denmark*

[2]*Copenhagen University Hospital- Herlev, The Fertility Clinic, Copenhagen, Denmark*

[3]*Zealand University Hospital- Koege, The Fertility Clinic, Koege, Denmark*

[4]Faculty of Health and Medical Sciences- University of Copenhagen, Department of Pharmacy, Copenhagen, Denmark

Study question: How is the anti-inflammatory response in human follicles controlled during the ovulatory process leading to the expulsion of the oocyte?

Summary answer: Intrafollicular concentrations of cortisol becomes high close to ovulation concomitant with an exceptionally high biological activity securing a timely and efficient termination of inflammatory processes.

What is known already: Ovulation has been described as a local controlled inflammatory process resulting in the degeneration of the follicle wall to facilitate oocyte extrusion. Ovulation also affects glucocorticoid metabolism of granulosa cells (GC) and although *de novo* synthesis of cortisol only occurs in the adrenal cortex the mid-cycle surge induces a change from high expression of HSD11b2, inactivating cortisol to cortisone, to high expression of HSD11b1 which reversibly catalyses cortisol production from cortisone. Furthermore, the high concentrations of progesterone and 17-OH-progesterone within follicles cause dislodging of cortisol from cortisol binding protein (CBP) thereby activating the biological activity of cortisol.

Study design, size, duration: This prospective study included 50 women undergoing fertility treatment according to a standard antagonist protocol at the fertility clinic at the university hospital of Koege, Denmark. Women donated one follicle for research purpose aspirated at one of four time points during the process of final maturation of follicles; T = 0h, T = 12h; T = 17h; T = 32h and then one additional follicle at OPU at T = 36h

Participants/materials, setting, methods: The concentration of cortisol and cortisone together with sex steroids were measured by LC-MS/MS in follicular fluid (FF) collected at the above five time points. Whole genome microarray data, validated by q-PCT analysis, was used to evaluate gene expression of *CYP11b1, CYP21A2, HSD11b1, HSD11b2* and *NR3C1* in GC at the five different time points.

Main results and the role of chance: The expression of *HSD11b1* is strongly upregulated during the ovulatory process. From 0-12h expression is increased 690 times reaching more than 20.000 times higher than at T = 0 during the remaining period. In contrast, expression of *HSD11b2* is quickly downregulated by 15-20 times through the ovulatory process.

The concentration of cortisol is different from the gene expression but increases significantly from a few ng/ml at T = 0h to around 15 ng/ml at T = 12h—17h and peaks at 40-50 ng/ml at T = 32h—36h. In contrast, cortisone is almost constant from 0 to 17h at a concentration of 30-40 ng/ml being significantly reduced to 10-20 ng/ml at T = 32—36h.

Concentrations of progesterone and 17-OH-progesterone increased during the ovulatory process to high levels which in essence displaces cortisol from its binding protein CPB, due to similar binding affinities. This will contribute to high levels of biologically active cortisol close to ovulation, which allows the inflammatory reaction to act on the follicle wall and secure extrusion of the oocyte to oviduct before becoming inhibited by cortisol.

Furthermore, a significant decrease in 11-deoxycortisol expression was seen but *CYP11B1* expression was below detection limit in GCs. This study provides new information on human ovulation.

Limitations, reasons for caution: Although 50 women were included more observations at each specific time point would have strengthened the conclusions.

Wider implications of the findings: For the first time, this study collectively evaluates the temporal effect of cortisol and cortisone concentrations in connection with gene expression profiles of enzymes involved in regulation the inflammatory response during human ovulation which now forms a physiological framework for understanding potential dysregulations in the involved processes.

Trial registration number: NA

O-248 Treatment with antifibrotic targets decreases accumulation of pro-fibrotic myofibroblasts and fibrotic collagen in cultured cryopreserved-thawed human cortical tissue

J.S. Del Valle[1], R.W.J. Van Helden[1], J.D. Asseler[2,3,4], L.A. Louwe[5], G.S.K. Pilgram[5], J. Metzemaekers[6], L.A.J. Van der Westerlaken[5], N.M. Van Mello[2,4], S.M. Chuva de SousaLopes[1]

[1]LUMC, Anatony and Embryology, Leiden, The Netherlands
[2]Vrije Universiteit Amsterdam, Obstetrics and Gynaecology, Amsterdam, The Netherlands
[3]Amsterdam UMC, Reproduction and development research institute, Amsterdam, The Netherlands
[4]Amsterdam UMC, Centre of Expertise on Gender Dysphoria, Amsterdam, The Netherlands
[5]LUMC, Gynecology, Leiden, The Netherlands
[6]LUMC, Obstetrics, Leiden, The Netherlands

Study question: Could the excess deposition of fibrotic collagen and the presence of myofibroblast be reversed by *in vitro* culture of human cortical tissue with antifibrotic targets?

Summary answer: The *in vitro* treatment of fibrotic ovarian stroma with Metformin, Pirfenidone or Mitoquinone proved effective in decreasing collagen accumulation and the presence of myofibroblasts.

What is known already: Tissue fibrosis is characterized by an excessive accumulation of extracellular matrix proteins, leading to organ dysfunction. The ovary is the first organ to show fibrosis related to ageing, creating permissive conditions for ovarian cancer development. Due to this, there is an urgent need for ovarian fibrosis treatments. The clinically approved treatment with Metformin has shown efficacy in preventing fibrosis progression from postmenopausal ovaries obtained from diabetic patients, while Pirfenidone is used to treat pulmonary fibrosis. Transmasculine people exposed to prolonged androgen therapy show early signs of ovarian fibrosis, providing a suitable model to study ovarian fibrosis management strategies

Study design, size, duration: duration Fresh and cryopreserved-thawed human ovarian samples obtained from 9 cisgender women (cOVA) and 9 transgender and gender diverse people (tOVA) were included for histological analysis of collagen content and fiber organization. Cryopreserved-thawed cortical fragments from 6 tOVAs were cultured for 8 days with or without antifibrotic treatments (Metformin, Pirfenidone and Mitoquinone). Cryopreserved-thawed cortical fragments from 9 tOVAs were used for *in vitro* culture, followed by metabolic assays.

Participants/materials, setting, methods: Human ovarian samples were obtained from 9 cisgender women (29,1,3 ± 7,9years) scheduled for gonadotoxic therapy undergoing oophorectomy for fertility preservation and from 24 transgender and gender diverse people (22,7 ± 2,4 years) undergoing gender affirming oophorectomy. Collagen content and organization were visualized by second harmonic generation and polarized light imaging. Collagen type 1 and 4, ACTA2+ myofibroblasts and TUNEL+ apoptotic cells were detected and quantified using immunofluorescence. Mitochondrial respiration and glycolysis were measured using the Seahorse XF analyzer.

Main results and the role of chance: Histological analysis of collagen content and organization confirmed that tOVA from subjects in fertile age presents characteristics of ovarian fibrosis, such as a higher accumulation and anisotropic (linearized) organization of collagen fibers within the stroma, indicating that long exposure to androgen therapy affects the extracellular matrix composition of the ovary. Furthermore, both tOVA and cOVA cortical tissue showed an increase in anisotropic collagen disposition after being cryopreserved-thawed when compared to its fresh counterpart, indicating cryopreservation could favor fibrotic progression. Additionally, standard *in vitro* culture of cryopreserved-thawed ovarian cortical fragments promotes an accumulation of collagen 1 and 4 as well as an increase in the number of myofibroblasts and apoptotic cells after 8 days of culture. Treatment with antifibrotics targets such as Pirfenidone, Metformin and Mitoquinone proved to be efficient in reducing both collagen accumulation ($P < 0.05$), pro-fibrotic myofibroblasts ($P < 0.05$) and TUNEL+ apoptotic cells ($P < 0.05$). These results support the evidence that ovarian fibrosis can be prevented or reverted *in vitro* with anti-oxidants and drugs targeting inflammatory response. As such, these

treatments should be considered as therapeutic approaches for women of advancing age and metabolic disorders to prevent pro-tumorigenic fibrotic ovarian stroma.

Limitations, reasons for caution: Small sample size. There is variation in the type and duration of the androgen treatment in transgender and gender diverse people included in the study. Furthermore, the collagen analysis from the cOVA samples was performed on 1cm^2 biopsies that might not represent the general collagen distribution in the complete ovary.

Wider implications of the findings: Medical treatments affecting the ovarian metabolic cell function, such as androgen therapy for transgender people and gender diverse or lab procedures to cryopreserved human ovarian tissue, can trigger fibrosis progression. Nevertheless, human ovarian fibrosis seems reversible and preventable using drugs targeting mitochondrial metabolism and inflammatory response.

O-249 Calcium directly influences pituitary function through the Calcium Sensing Receptor (CaSR)

N.N. Poulsen[1], J. Hjerresen[1], L. Juel Mortensen[1], K. Sørensen[2], A. Juul[1], M. Blomberg Jensen[1]

[1]Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark
[2]Copenhagen University Hospital - Rigshospitalet, Department of Pediatrics and Adolescent Medicine, Copenhagen, Denmark

Study question: Does calcium have a direct effect on pituitary function through CaSR?

Summary answer: CaSR is important for Hypothalamus-pituitary-gonadal (HPG) axis signaling, and lack of CaSR in the anterior pituitary leads to smaller reproductive organs in female mice.

What is known already: In a randomized clinical trial, prepubertal children were given calcium supplementation or placebo and girls in the intervention group went into puberty 5 months earlier than the placebo group. This effect was not detected in the boys who participated. CaSR is the main receptor for systemic calcium homeostasis, and its presence has been established in the anterior pituitary.

Study design, size, duration: We performed a mouse study comparing knock-out mice with a deletion of the CaSR in the anterior pituitary to wild-type mice. 13/13 female and 6/13 male knock-out/controls mice were included in the study.

Participants/materials, setting, methods: Female and male knock-out and control mice were sacrificed at 8 weeks. We obtained blood samples and reproductive organs was dissected, weighted and stored at -80 °C or stored in formalin before being paraffin embedded.

Main results and the role of chance: Female reproductive organs showed significantly lower weight when comparing CaSR knock-out to control mice. This includes ovary weight (3.7 mg vs. 6.4 mg; $p = 0.0004$) and uterus weight (27.9 mg vs. 67.0 mg; $p = 0.0008$). The weight difference was still significant after correcting for total body weight (organ weight/total body weight%): (0.02176 vs. 0,03534; $p = 0.0035$ and 0.1788 vs. 0.3826; $p = 0.0023$ respectively).

We did not observe a significant difference in male reproductive organs, nor any difference in pituitary weight in either sex.

Limitations, reasons for caution: The difference in reproductive organ weights is interesting, but it is also an early finding. Further analysis of the collected organs and blood samples will be conducted to further investigate the phenotype of the mouse model. We are also looking into correcting weight differences for estrous cycle effects.

Wider implications of the findings: If CaSR proves to be important for the regulation of the HPG-axis, it has a clinical perspective since CaSR can be modulated by the drug Cinacalcet, an allosteric agonist of CaSR, already on the market where it is used to treat kidney patients.

O-250 Increased association of eating disorders in women with polycystic ovary syndrome

M.S. Paredes Contreras[1], J.D. Treviño Báez[1], A. Forgiarini[3], L.O. De la O Pérez[1], M.R. Moraga Sánchez[2], E. Saucedo de la Llata[2]

[1]Instituto Mexicano del Seguro Social, High Specialty Medical Unit- Obstetrics and Gynecology Hospital No. 23, Monterrey, Mexico
[2]Imar Clinic, Assisted Reproduction, Murcia, Spain
[3]Next Fertility Valencia, Assisted Reproduction, Valencia, Spain

Study question: Is an increased association of eating disorders (ED) in women with polycystic ovary syndrome (PCOS) than in women without PCOS?

Summary answer: Women with PCOS have an increased association of ED than women without PCOS.

What is known already: PCOS is one of the most common endocrinopathies in women. It has been reported to be associated with psychological distress and dissatisfaction with self-appearance due to clinical features of the syndrome, such as hyperandrogenism, metabolic disorders, obesity, and infertility, leading to lower self-esteem and an increased risk of developing ED. This association presents a clinical dilemma, as the primary treatment for PCOS emphasizes the importance of weight loss, leading to potential distress in patients and worsening ED behaviors.

Study design, size, duration: This was a cross-sectional study. The sample size was calculated with the formula for comparison of proportions in two independent groups, with a confidence level of 95% and power of 80%, obtaining a minimum sample size of 116 participants per group. We included a total of 643 women between July to August 2022.

Participants/materials, setting, methods: 643 women who attended a gynecological consultation in Murcia, Spain were included, 238 with PCOS and 450 controls. The information was collected online. The score of the EDE-Q questionnaire and the clinical epidemiological characteristics were compared between the groups. Pearson Chi-square was used for categorical variables, and Mann Whitney U test for quantitative variables. Statistical significance was considered with a P-value <0.05. The data were analyzed with the SPSS version 20.

Main results and the role of chance: We found an increased risk of presenting ED in women with PCOS than in women not reporting PCOS (27% vs 13.7%). The odds of presenting an abnormal EDE-Q score (>4) were greater in women with PCOS (odds ratio [OR] 2.325, 95% confidence interval [CI], 1.55, 3.47, $P < 0.001$) than in women without PCOS. Clinically significant elevated scores were observed in the PCOS group for all four subscales of ED, but with a more significant impact on the eating concern scale (OR 2.49, 95% CI, 1.47, 4.21, $P < 0.001$). We found more prevalence of binge episodes in the PCOS group (OR 1.8, 95% IC, 1.3, 2.5, $P < 0.001$). When evaluating the characteristic of women with diagnosis of PCOS, we observed a higher body mass index (30.4 vs 23.4 [95% CI, 0.89-1.4, $P < 0.001$]) and more prevalence of amenorrhea (100% vs 87%, $P < 0.001$) in women with ED diagnosis than in women without ED.

Limitations, reasons for caution: The limitations observed in our study were that the information was based on an online questionnaire, so there is a possible reporting bias or misunderstanding of the questions.

Wider implications of the findings: The present study shows that women with diagnosis of PCOS have an increased risk of presenting ED than women without PCOS. This is more prevalent in women with a longer period of amenorrhea and a higher body mass index.

O-251 LIN28B gene expression is downregulated in spermatozoa of oligozoospermic men and associates with genetic variants previously linked to pubertal onset

M. Lardone[1], C. Espinoza[1], E. Ortiz[1], M. Diaz-Fontdevila[1], P. Inostroza[1], G. Iniguez[1], M. Ebensperger[1], K. Almstrup[2], A. Castro[1]

[1]*University of Chile. Faculty of Medicine, Institute of Maternal and Child Research, Santiago, Chile*
[2]*Rigshospitalet- University of Copenhagen, Department of Growth and Reproduction, Copenhagen, Denmark*

Study question: Is there an association between genetic polymorphisms in *LIN28B* with *LIN28B* expression and semen quality in spermatozoa from oligozoospermic men?

Summary answer: *LIN28B* is downregulated in spermatozoa of oligozoospermic men and explains 39% of sperm count variability. One SNP (rs314280) was associated with low *LIN28B* mRNA expression.

What is known already: Large-scale genomic studies have identified genetic variants in or near *LIN28B* to be robustly associated with pubertal traits such as age at menarche and age at voice break. The LIN28 family of genes are known to control cell division, growth and differentiation. The LIN28B orthologue is exclusively expressed at high levels in the testis and placenta; however, we have limited knowledge about the role of LIN28B in relationship to testicular function. Interestingly, other studies have showed that later onset of puberty is associated with poor semen quality, suggesting that pubertal development may influence adult testicular function.

Study design, size, duration: Twenty-nine oligozoospermic (cases) and fifty-four men with normal sperm concentration (controls) were recruited from patients seeking andrological work-up for male/couple infertility at a University Hospital. Subjects with abnormal karyotype, Yq-microdeletions, varicocele GIII-IV, hypogonadotropic hypogonadism, seminal infection, diabetes, BMI>35, excessive consumption of alcohol/drugs, testicular cancer, chemotherapy/radiotherapy were excluded. Semen samples were obtained for analysis (WHO, 2010) and sperm isolation by density gradient (PureSperm40®). Peripheral blood samples were analysed for reproductive hormones and used for DNA extraction.

Participants/materials, setting, methods: *LIN28B* and *GAPDH-S* mRNA abundance were measured by qRT-PCR ($2^{-\Delta CT}$ method) in RNA isolated from purified sperm using SYBR® MasterMix (Takyon). Five SNPs in linkage disequilibrium (rs7759938, rs395962, rs314268, rs314277 and rs314280) were genotyped (TaqMan™ SNP Genotyping Assay). Statistical differences between groups were assessed by Mann-Whitney test and genetic association was analysed using "SNPassoc" package in R. Values are showed as median, Q1-Q3.

Main results and the role of chance: Cases and controls had similar age and BMI but as expected sperm concentration, morphology and vitality were differed between groups (9.9, 4.9-13.1 vs 82.8, 46.0-146.5 mill/ml; 1, 1-2 vs 3, 1-4% normal forms and 83%, 76-89 vs 86%, 82-90, respectively) ($p < 0.05$). No differences were observed in progressive motility, semen volume and days of abstinence. FSH and LH serum levels were higher in cases compared with controls (4.6, 2.6-7.8 vs 3.2, 2.5-4 mIU/ml and 4.2, 2.9-5.2 vs 3.1, 2.1-4.2 mIU/ml, respectively; $p = 0.019$ and $p = 0.017$). Relative expression of *LIN28B* was significantly diminished in cases compared with controls (0.0034, 0.0015-0.0103 vs 0.0446, 0.0122-0.1026; $p < 0.001$), while expression of the internal housekeeping control *GAPDH-S* was similar between groups. Linear regression model showed significant association of sperm concentration and total sperm count with *LIN28B* relative expression adjusted by age, abstinence time, % progressive motility and % normal morphology (beta=0.408, R^2=0.241, $p < 0.001$ and beta=0.461, R^2=0.393, $p < 0.001$). *LIN28B* rs314280 was associated with mRNA expression in the dominant model ($p = 0.025$) and two other SNPs (rs7759938, rs314268) showed the same trend ($p = 0.09$). Men with at least one minor allele of these 3 SNPs had a lower *LIN28B* mRNA abundance ($p = 0.006$; $p = 0.07$; $p = 0.055$).

Limitations, reasons for caution: Genotype frequency comparisons between cases and control were not conducted because of the small sample size. A larger cohort will be studied to address this assumption and association of genotypes with parameters of semen quality.

Wider implications of the findings: To our knowledge this study represents the first report on *LIN28B* expression and human testicular function. The significant direct association of *LIN28B* mRNA expression with sperm concentration suggests that *LIN28B* may be involved in spermatogonial proliferation.

Trial registration number: not applicable

O-252 Genetic characterization of human sperm centrosome defects in infertile couples with complex embryo aneuploidy

S. Tsai[1], P. Xie[1], S. Cheung[1], O. Kocur[1], A. Aluko[1], Z. Rosenwaks[1], G. Palermo[1]

[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.*

Study question: Can we characterize the genetic aspects related to sperm centrosome dysfunction in couples with high embryo aneuploidy that cannot exclusively be attributed to the oocyte?

Summary answer: We characterized structural and genomic abnormalities responsible for sperm centrosome dysfunction in infertile couples with complex embryo aneuploidy not exclusively related to the female partner.

What is known already: Conventional semen analysis provides only limited information on the proper function and embryo developmental competence of the male gamete. Therefore, an ancillary test, such as sperm chromatin fragmentation (SCF) and particularly double-stranded DNA breaks, has been claimed responsible for structural chromosomal abnormalities. It remains puzzling the source of complex embryo aneuploidy and chaotic chromosomal mosaicism that cannot solely be attributed to the female partner. The availability of genomic analysis may shed light on the integrity and function of the sperm centrosome responsible for ordaining chromosomal distribution at the first mitotic division.

Study design, size, duration: In the past 4 years, we identified 13 couples with unexpected high poor embryo cleavage resulting in a higher number of embryos with complex aneuploidy not solely attributable to the female gamete, resulting in extremely poor embryo implantation. Therefore, ancillary testing on the spermatozoa of the male partners was carried out to determine if the couple's reproductive failure was eventually due to a stealth male gamete deficiency.

Participants/materials, setting, methods: Thirteen couples with poor clinical outcomes, characterized by poor embryo cleavage, high and complex embryo aneuploidy not exclusively due to the oocyte, with poor embryo implantation in multiple IVF/ICSI cycles, were offered adjuvant male partner testing including centrosome assessment through immunofluorescence staining on centrin (normal $\geq$ 60%), sperm chromatin fragmentation testing through terminal deoxynucleotide dUTP transferase nick-end labeling (TUNEL, normal $\leq$ 15%), transmission electron microscopy (TEM), and whole exome sequencing (WES) on spermatozoal DNA.

Main results and the role of chance: In 13 couples with an average paternal age of 38.1 ± 2 years, semen analysis revealed a volume of 22.2 ± 1.4mL, concentration of 58.2 ± 37x106/mL, motility of 35.2 ± 18% and normal morphology of 2.6 ± 1%. They underwent with female partners (maternal age of 37.2 ± 2 years) a total of 16 ICSI cycles with aneuploidy testing. Only 11 cycles yielded embryos for transfer due to poor embryo development with high aneuploidy rate, and none of them achieved a pregnancy.

Centrosome staining revealed that only 45.8 ± 22% of the spermatozoa displayed this key organelle. An overall SCF was observed at 16.7 ± 10%. TEM confirmed that approximately 70% of the spermatozoa had irregular proximal centrioles. Moreover, genomic analysis by WES revealed mutations on PLK4 gene responsible for centriole duplication, BRSK1 gene involved in centrosome duplication, TUBGCP6 gene responsible for centrosomal microtubule nucleation, MARK4 for centrosome localization, MAP1S for microtubule anchoring and DNA binding, RIC8A for chromosome distribution, and CALM3 for cytokinesis.

Of this cohort, 3 couples that subsequently underwent 3 ICSI cycles had their spermatozoa processed by microfluidics, aiming at selecting male gametes with higher genomic integrity. A fertilization rate of 78.3% (18/23) was achieved generating euploid embryos that resulted in 3 successful pregnancies.

Limitations, reasons for caution: We identified sperm centrosome dysfunction responsible for the peculiar and recurrent embryo aneuploidy. Although we identified shared gene mutations in those couples, these data are still preliminary. With exception of improving spermatozoa selection, there is a lack of a single effective treatment option to address sperm centrosome abnormality.

Wider implications of the findings: Ancillary tests with semen analysis were able to assess the function and competence of the male gamete. Corroborative genomic study can help provide insights into the reason for poor embryo implantation particularly those with high complex aneuploidy.

O-253 Novel biallelic variants in DNAH1 cause multiple morphological abnormalities of sperm flagella with favorable outcomes of fertility after ICSI in Han Chinese males

S. Long[1,2], L. Fu[3], J. Ma[1,2], H. Yu[1,2], X. Tang[1,2], W. Han[1,2], W. Liu[1,2], G. Huang[1,2], W. Lu[3], T. Lin[1,2]

[1]Women and Children's Hospital of Chongqing Medical University, Center for Reproductive Medicine, Chongqing, China
[2]Chongqing Health Center for Women and Children, Center for Reproductive Medicine, Chongqing, China
[3]National Research Institute for Family Planning, National Health Commission Key Laboratory of Male Reproductive Health, Beijing, China

Study question: Is there any novel variants and mutant hotspot in *DNAH1* gene related to multiple morphological abnormalities of sperm flagella (MMAF) and male infertility in humans?

Summary answer: We identified eighteen variants of *DNAH1* gene in eleven MMAF-affected Chinese men, including fourteen novel variants, four previously reported variants, and a candidate mutant hotspot.

What is known already: As a specific type of asthenoteratozoospermia, MMAF is characterized by composite flagellar defects including absent, short, coiled, angulation, and irregular-caliber, and usually presents ultrastructural abnormalities of axonemal and peri-axonemal structures. Genetic defects are the major cause of MMAF and biallelic variants of *DNAH1* have been found to account for approximately 30% of studied human MMAF cohorts. Males with *DNAH1* variants usually present with primary infertility owing to abnormal sperm morphology and motility. Intracytoplasmic sperm injection (ICSI) is the main strategy applied for patients with *DNAH1* variants to conceive.

Study design, size, duration: A total of thirty-five patients with MMAF phenotype were recruited from the center for reproductive medicine from August 2019 to June 2022. A next-generation sequencing (NGS) panel of 22 MMAF-related genes was applied for genetic testing and the hereditary pattern was confirmed with Sanger sequencing. Sperm morphological analysis, immunostaining assays, and assisted reproductive therapy were performed in 2021 and 2022.

Participants/materials, setting, methods: The *DNAH1* variants were identified by NGS and confirmed by Sanger sequencing. Pedigree analysis and *in silico* analysis further confirmed the pathogenicity or likely pathogenicity of these variants. Papanicolaou-staining, scanning and transmission electronic microscopy, and immunostaining were used to characterize the morphology and ultrastructure of spermatozoa. ICSI was applied for the assisted reproductive therapy of *DNAH1*-mutant patients and the outcomes of fertilization, embryo cleavage, and delivery were analyzed.

Main results and the role of chance: We totally identified 18 different *DNAH1* variants (NM_015512.5) in 11 of 35 MMAF-affected males, including 9 missense variants (c.7690G>A, p.A2564T; c.10970C>G, p.T3657R; c.5584G>A, p.G1862R; c.6887T>C, p.L2296P; c.12122C>T, p.T4041I; c.1832T>C, p.L611P; c.2738C>A, p.A913D; c.5795G>A, p.R1932Q; c.7066C>T, p.R2356W) and 9 loss-of-function variants (c.11726_11727delCT, p.P3909Rfs*33; c.12172C>T, p.Q4058*; c.5104C>T, p.R1702*; c.12210del, p.V4071Cfs*54; c.8533del, p.D2845Mfs*2; c.12178_12190del, p.E4060Pfs*61; c.2301-1G>T; c.4552C>T, p.Q1518*; c.12118_12119delCA, p.Q4040Dfs*33). Moreover, 77.8% (14/18) of the identified variants were novel. The results of Papanicolaou-staining, scanning electronic microscopy, and immunofluorescence demonstrated the typical characteristics of MMAF, consisting of absent, short, coiled, angulation, and irregular-caliber flagella, of the spermatozoa affected by *DNAH1* variants. Transmission electronic microscopy further revealed the compound changes of flagella ultrastructure, including loss of central pair and disorganization of microtubule doublets and outer dense fibers. Six of eleven underwent assisted reproductive therapy with ICSI in our clinic. The rates of fertilization, usable embryos and clinical pregnancy for patients with *DNAH1* variants following ICSI were 81.5%, 52.8% and 66.7%, respectively. To date, three couples have given birth to a total of five healthy children.

Limitations, reasons for caution: Because of distance and inconvenience, five of the eleven *DNAH1*-affected men didn't provide additional semen samples for functional analysis. In addition, as the absence of specific antibody of DNAH1, immunostaining for DNAH1 was not performed in this study.

Wider implications of the findings: This study significantly expands the variant spectrum of *DNAH1* gene related to MMAF and male infertility in humans. The systematic description of assisted reproduction therapies will provide clinicians with new insights into molecular diagnosis and genetic counseling.

O-254 ACTRT2 deficiency increases spermatogonia vulnerability to ferroptosis

H. Chen[1], Y. Li[1], C. Deng[2], X. Liang[1], G. Liu[1]

[1]The sixth affiliate hospital of Sun Yat-sen University, Reproductive medicine Center, Guangzhou, China
[2]The first affiliate hospital of Sun Yat-sen University, Department of andrology, Guangzhou, China

Study question: How does the actin-related proteins T2, ACTRT2, which is specifically expressed in spermatogonia, regulate spermatogonia death?

Summary answer: ACTRT2 deficiency in spermatogonia leads to intracellular iron overload and damage to mitochondria, ultimately increasing spermatogonia vulnerability to ferroptosis.

What is known already: ACTRT2 is tightly related to spermatogenesis. On the one hand, ACTRT2 is involved in regulating iron uptake in spermatogonia. ACTRT2 deficiency leads to intracellular iron overload and mitochondrial damage, ultimately increasing the vulnerability of spermatogonia to ferroptosis. On the other hand, for ACTRT2-related spermatogenic impairment, the survival of spermatogonia could be maintained by inhibiting ferroptosis, and spermatogenesis of the testis could be improved.

Study design, size, duration: The expression of ACTRT2 was knocked down in GC-1 cells (spermatogonial cell line). Busulfan was used to induce GC-1 cells death. And then to explore which type of cell death ACTRT2 was involved in, GC-1 cells were treated with 50 μM Z-VAD-FMK (apoptosis inhibitor), 50 μM necrostin-1 (necroptosis inhibitor), or 0.1 μM ferrostatin-1 (ferroptosis inhibitor).The mechanism by which ACTRT2 regulates ferroptosis in spermatogonocytes was investigated in ACTRT2 knockout mice.

Participants/materials, setting, methods: ACTRT2 expression was knocked down in vitro in GC-1 cells using siRNA. Then, GC-1 cell death was

induced using 150 μM busulfan. ROS levels, morphological changes in mitochondria, and the ferroptosis marker GPX4 were detected. ACTRT2 knockout mice were constructed in vivo using CRISPR/Cas9. The spermatogenesis of the mice was measured with H&E staining. After treatment with busulfan, ferrostatin-1 was used to inhibit ferroptosis in order to protect spermatogenesis.

Main results and the role of chance: ACTRT2 was specifically expressed in testicular tissue and was associated with spermatogenesis. In vitro, when the cells were treated with busulfan, the proportion of GC-1 cell death in the low-ACTRT2 group increased significantly compared with the si-NC group. Furthermore, ferrostatin-1 significantly improved the survival of busulfan-treated cells. In low-ACTRT2 GC-1 cells, ROS accumulation and typical mitochondrial changes associated with ferroptosis occurred, and GPX4 was downregulated. In vivo, the seminiferous tubules in ACTRT2-/- mice were significantly shrunken. In addition, after being treated with busulfan, spermatogenesis in ACTRT2+/- mice decreased significantly compared to that in wild-type mice. In ACTRT2+/- testes, the expression levels of ACSL4 and ALOX15 were upregulated, while the expression levels of SLC7A11 and GPX4 were downregulated. Then, ferrostatin-1 was administered, which resulted in improved spermatogenesis. Finally, we found that the expression of SLC11A2, IREB2, and TFRC increased significantly in the low-ACTRT2 group, which transports iron into the cell to increase the intracellular unstable iron pool. Meanwhile, the expression of SLC40A1, which transports excess iron out of the cell, significantly decreased.

Limitations, reasons for caution: We found that ferrostatin-1 can inhibit ferroptosis in ACTRT2-deficient spermatogonia, which is expected to be a new therapeutic strategy for male infertility. However, its safety and efficacy still need to be further evaluated, and the therapeutic schedule still needs to be further explored and optimized.

Wider implications of the findings: Ferrostatin-1 can inhibit ferroptosis in ACTRT2-deficient spermatogonia, which is expected to be a new therapeutic strategy for male infertility.

O-255 microRNA-23a/b-3p regulate expression levels of testis-specific transcripts in men with impaired fecundity

L.S. Becker[1], M. A. Al Smadi[2], H. Koch[1], E. Meese[1], M. Abu-Halima[1]

[1]*Saarland University, Institute of Human Genetics, 66421 Homburg/Saar, Germany*
[2]*King Hussein Medical Centre, Reproductive Endocrinology and IVF Unit, Amman, Jordan*

Study question: To investigate whether microRNA-23a/b-3p targets spermatogenesis-related transcripts and whether this targeting impacts their expression contents in patients with subfertility.

Summary answer: The higher expression of microRNA-23a/b-3p and lower expression of 11 tested target genes are associated with men subfertility

What is known already: Spermatogenesis is a complex and highly regulated process, many genes are involved, the expression levels of which are strongly or partially coordinated by microRNAs (miRNAs). MiRNAs are small, non-coding RNAs that are involved in the post-transcriptional regulation of gene expression. Transcriptome analysis shows that hundreds of genes are expressed exclusively or predominantly in male germ cells including *CEP41, G2E3, GOLGA6B, GOLGA6C, LMLN, NOL4, PAPOLB, PCDHA9, RGPD1, SOX6*, and *ZNF695* genes, which play a crucial role during spermatogenesis and/or sperm function. However, the expression regulation of these genes is still unclear.

Study design, size, duration: Reverse transcription-quantitative PCR (RT-qPCR), dual luciferase assay, Western blot, and bioinformatics analysis were used to validate the lower expression of 11 target genes as a result of the known higher expression of microRNA-23a/b-3p in men with subfertility. A total of 82 men were included for RT-qPCR, consisting of 41 oligoasthenozoospermic subfertile men who attended the IVF center for infertility treatment and 41 age-matched normozoospermic volunteers who served as controls.

Participants/materials, setting, methods: In *silico* prediction and dual-luciferase assays were performed to evaluate the potential links between the higher expression of microRNA-23a/b-3p and the lower expression of 11 genes. Total RNA, including miRNA, was isolated from the sperm of oligoasthenozoospermic (n = 41) and normozoospermic men (n = 41). RT-qPCR was used to detect the expression levels of 11 target genes. Correlation analyses between the mRNA expression levels and basic semen parameters were carried out.

Main results and the role of chance: The expression levels of microRNA-23a/b-3p were significantly up-regulated and 11 genes were significantly down-regulated in oligoasthenozoospermic men compared with age-matched normozoospermic men as determined by RT-qPCR. Using dual-luciferase assays, 9 genes including *CEP41, G2E3, GOLGA6C, NOL4, PAPOLB, PCDHA9, RGPD1, SOX6*, and *ZNF695* were identified as direct targets of miR-23a-3p and 4 genes including *GOLGA6C, PAPOLB, SOX6*, and *ZNF695* were identified as direct targets of miR-23b-3p. Mutations in the miR-23a/b-3p binding site within the 3′untranslated regions (3′UTRs) of the 9 target genes, which target either miR-23a-3p and/or miR-23b-3p, resulted in abrogated responsiveness to microRNA-23a/b-3p and confirmed that *CEP41, GOLGA6C, NOL4, PCDHA9*, and *SOX6* as direct targets for miR-23a-3p and *NOL4, SOX6* and *PCDHA9* as direct targets for miR-23b-3p. Correlation analysis highlighted sperm count, motility, and morphology were positively correlated with the lower expression level of these validated genes.

Limitations, reasons for caution: Despite the correlation between the higher expression of microRNA-23a/b-3p and the lower expression of the validated genes, further validation by Western blotting in human sperm and testicular tissues is needed.

Wider implications of the findings: Findings suggest that the higher expression of microRNA-23a/b-3p or the lower expression of validated target genes are associated with male subfertility, probably through influencing the basic semen parameters. This study lay the groundwork for future studies focused on investigating therapies for male infertility.

[4]*University of Opole, Institute of Chemistry- Department of Pharmacy and Ecological Chemistry, Opole, Poland*

Study question: Is Proton NMR seminal plasma assessment a valid method for identifying biomarkers allowing to predict top-quality (TQ) embryo development?

Summary answer: Biomarkers important in the context of male fertility can be assessed using proton NMR

What is known already: Currently, the quality of sperm is assessed predominantly by examining its concentration, motility, and morphology. These parameters are insufficient in diagnosing male infertility and predicting treatment outcomes with assisted reproductive technology (ART). Metabolomics techniques have been shown to be potentially useful in identifying biomarkers related to infertility. It has been proven, using proton NMR, that there are a number of substances in the semen plasma that correlate with various physiological states of patients and may potentially indicate impaired functioning of various metabolic pathways. However, the relationship between biomarkers and embryo development has not yet been investigated

Study design, size, duration: This was a prospective case-control study and consisted of 30 semen samples from 13 patients who underwent IVF

treatment between January – March 2022 at INVICTA Fertility Centre, Poland. Sperm motility, concentration, morphology, and DNA fragmentation of the samples were assessed. Before sperm preparation for fertilization, semen was frozen to perform 1H NMR analyses, which were preceded by centrifugation in order to separate the plasma. NMR analysis results were compared to the embryological results.

Participants/materials, setting, methods: It was possible to identify preselected biomarkers in semen plasma through the use of reference spectra and to quantify their concentrations using the internal standard addition method. Their relative concentrations (separately and in pairs) were collated with semen parameters, embryo development data and pregnancy outcomes. A Machine Learning approach was employed to identify the most important variables, which were then used for further modelling with the use of LGBM models.

Main results and the role of chance: NMR allows for the identification and measurement of biomarkers important in the assessment of the fertility potential of semen. The presence of amino acids, organic acids, sugar residues and fatty acid derivatives was confirmed by applying this technique. It was found that the concentration of these biomarkers is an individual feature - probably dependent on the physiological state of the organism. The results indicate that the ratios of biomarker concentrations to each other are more important than their individual concentrations. Machine learning modelling showed a strong correlation of several compounds with the chance of obtaining a TQ blastocyst. The amount of taurine, glutamic acid and choline together with its derivatives seem to be the most important factors in blastocyst development. The results indicate that if the amount of glutamic acid significantly surpasses glycerophosphocholine, choline exceeds taurine, the amount of taurine is higher than that of citrate, or the amount of choline is significantly higher than its phosphorus analogue the likelihood of obtaining a TQ blastocyst is higher. This would suggest that several metabolic pathways as the Krebs cycle, the one-carbon cycle or choline metabolism were modified signalling pathological conditions which the standard assessment of semen parameters cannot detect.

Limitations, reasons for caution: The NMR technique allows a fast determination of the content of many biomarkers, but results are in the mmol/l range. The results should be confirmed in a larger group of patients with different semen disorders

Wider implications of the findings: NMR allows for the rapid creation of unique metabolic profiles of patients, which can ensure the creation of personalized treatments for male infertility and the selection of sperm with the highest chance of obtaining a TQ blastocyst

Trial registration number: The studies were approved by the Ethics Committee at the Gdansk Regional Medical Board (No KB-3/22).

O-257 IGF2BP3 induces apoptosis of spermatogenic cells by regulating the stability of Tcf4 mRNA in an m6A-dependent manner, thereby affecting the occurrence of azoospermia

M. Dong[1], Z. Xue[2], S. Weihao[2], T. Jichun[1]

[1]*Shengjing Hospital of China Medical University, 1.Center of Reproductive Medicine, Shenyang, China*
[2]*China Medical University, School of Life Sciences, Shen yang, China*

Study question: Does IGF2BP3 regulate *Tcf4* mRNA stability in an N6-methyladenosine (m6A)-dependent manner, affect spermatogenesis, and lead to idiopathic non-obstructive azoospermia (iNOA)?

Summary answer: IGF2BP3 induces apoptosis of spermatogenic cells by regulating the stability of Tcf4 mRNA in an m6A-dependent manner, which in turn affects spermatogenesis leading to iNOA.

What is known already: Azoospermia is the most serious phenotype of male infertility, affecting approximately 10-15% of male infertility patients. iNOA refers to a class of non-obstructive azoospermia of unknown etiology for which there is no effective treatment. The etiology of iNOA is poorly understood, and its genetic and molecular mechanisms are poorly studied. IGF2BP3 was found to be highly expressed in tumor tissues and to be a post-transcriptional regulator in cancers. The study found that IGF2BP3 is an m6A reading protein that recognizes mRNA m6A modification and enhances mRNA stability and translation.

Study design, size, duration: We collected testicular tissue from 120 iNOA and 120 patients with obstructive azoospermia through prospective studies to analyze differentially expressed genes by high-throughput RNA sequencing.

Participants/materials, setting, methods: IGF2BP3 knockout and overexpression mouse models were constructed. Spermatogenesis was assessed by immunostaining, HE staining, spermatogenic specific gene expression, and computer-assisted sperm analysis (CASA). The stability of target mRNA was conducted by ActD. Merip-qRCR was used to detect IGF2BP3 binds to the target gene in an m6A-dependent manner; the m6A modification site of Tcf4 was predicted by SRAMP and verified by double luciferase reporting experiments. Overexpression Tcf4 to analyze its effect on spermatogenesis.

Main results and the role of chance: RNA-seq showed that IGF2BP3 was lowly expressed in iNOA testicular tissue which was verified by qRT-PCR and immunohistochemistry. After knocking down IGF2BP3, the spermatogenesis process is impaired, HE showed that the arrangement of spermatogenic cells in the seminiferous tubule was disordered and reduced, the spermatogonia and spermatoblasts were significantly reduced, and there were very few sperm in the seminiferous tubule. CASA showed that sperm density was significantly lower than that of the control group ($p < 0.05$). Western blot and qRT-PCR showed that spermatogenic cells-specific genes Nanos3, Sycp3, Tnp1, proliferation indexes PLZF and PCNA were all reduced compared with the control group. Overexpression of IGF2BP3 can reverse spermatogenesis in azoospermia mice; after knocking down IGF2BP3, the fertility of mice in vivo and in vitro was impaired; apoptosis of spermatogenic cells increased in testicular tissues of mice after knocking down IGF2BP3 and decreased in mouse testicular tissue after knocking down IGF2BP3. IGF2BP3 induces apoptosis of spermatogenic cells by regulating the stability of *Tcf4* mRNA in an m6A-dependent manner, resulting in impaired spermatogenesis; overexpression of Tcf4 in GC1 cells knocked down IGF2BP3 reduces apoptosis and increases cell proliferation.

Limitations, reasons for caution: In this study, we constructed knockdown and overexpression mice models by in situ injection of IGF2BP3 lentivirus in the testes, and the results were more accurate if conditional knockout mice model was used.

Wider implications of the findings: We found direct clinical and in vivo animal model evidence for the causes of male infertility in patients with idiopathic non-obstructive azoospermia, and for the first time found that IGF2BP3 affects spermatogenesis by regulating the stability of target genes in an m6A-dependent manner.

Study question: Does the composition of vaginal microbiota affect the success of IVF-ET? Does vaginal microbiota profile change intra-individually from IVF-ET to early pregnancy?

Summary answer: *L. crispatus* is associated with successful IVF outcome. The individual composition of vaginal microbiota tends to shift towards *Lactobacillus*-dominance between IVF-ET and early pregnancy.

What is known already: *Lactobacilli* are the most abundant species in healthy female reproductive tract microbiota and especially *Lactobacillus crispatus* is associated with good gynecological health. The composition of vaginal microbiota may also play an important role in infertility and the success of IVF. Women with *Lactobacillus*-dominated vaginal microbiota may have higher pregnancy rates after IVF-ET compared to women with non-*Lactobacillus* dominance, but the results have been controversial. In healthy pregnancy, vaginal microbiota is usually *lactobacilli*-dominated, whereas miscarriages are associated to a non-lactobacillus dominance. The intra-individual shift on the vaginal microbiota from ET to early pregnancy has not been studied earlier.

Study design, size, duration: This observational and longitudinal study investigates the effect of vaginal microbiota on the success of fresh IVF-ET. Another aim was to study the intra-individual changes in the microbiota profile between IVF-ET and early pregnancy. We recruited 76 subfertile women undergoing IVF with their own gametes between November 2019 and September 2021 in the Reproductive Medicine Unit, Helsinki University Hospital and in Oulu University Hospital. Main outcomes were clinical pregnancy and live birth.

Participants/materials, setting, methods: Study population composed of 76 subfertile women under 40 years of age. One IVF cycle including fresh embryo transfer was studied. Vaginal swabs were taken at the time of IVF-ET and at 8th gestational week. Samples were frozen in − 20 °C and moved to − 80 °C within four weeks. Microbiota analysis was performed with next-generation sequencing of 16S rRNA gene using Illumina MiSeq technology. Clinical data were collected from the patient registries and background questionnaires.

Main results and the role of chance: Altogether 30 (39.5%) of the 76 women achieved pregnancy after IVF-ET and 26 (34.2%) had live birth. The relative abundance of *L. crispatus* among women who achieved clinical pregnancy (46.9% vs. 19.1%, q = 0.003) and live birth (43.3% vs. 19.1%, q = 0.006) was significantly higher compared to women who did not. After adjusting for age, parity and gravidity, the results remained similar when comparing clinical pregnancy (q = 0.039), but in live birth, the difference lost significance (q = 0.14)

Vaginal samples were taken at the 8th gestational week from 21 of 30 women who got pregnant. All samples were dominated by *Lactobacillus* species, mainly by *L. crispatus* (n = 16, 76.2%). Only two (9.2%) women had *L. iners* dominated microbiota at the early pregnancy. When comparing samples taken during fresh IVF-ET and early pregnancy, *L. crispatus* had significantly higher relative abundance in early pregnancy samples compared to the samples taken at the ET (71.5% vs. 43.4%, q = 0.001), whereas the relative abundance of *L. iners* (10.1% vs. 24.1%, q = 0.004), and *G. vaginalis* (0.8% vs. 14.7%, q = 0.004) decreased. Altogether 13 women had an intra-individual shift in their microbiota profiles.

Limitations, reasons for caution: The small sample size was the main limitation of our study. Larger studies are needed to confirm our findings and their relationship with the success of IVF-ET.

Wider implications of the findings: Vaginal microbiota at the time of fresh IVF-ET has an impact of the success of IVF treatment. Also, the intra-individual composition of vaginal microbiota between IVF-ET and early pregnancy changes in some women. The vaginal microbiota modification through probiotics in order to optimize the result of IVF warrants more studies.

O-259 1.\tComparison of endometrial versus vaginal microbiota in 71 infertile patients

P. Finzer[1], A. Polifke[1], A. Von Schwedler[2], R. Gulba[2], N.N.R. Nassar[3]

[1]dus.ana Düsseldorf Analytik, Praxis für Medizinische Mikrobiologie und Laboratoriumsmedizin, Düsseldorf, Germany
[2]Institut für Medizinische Mikrobiologie und Krankenhaushygiene, Mikrobiologie, Düsseldorf, Germany
[3]novum, Zentrum für Reproduktionsmedizin, Essen, Germany

Study question: 1.Mostly, endometrial microbiome probes are acquired by trans-cervical sampling using a "pipelle". However, it is unclear, whether this approach "contaminates" the endometrial material.

Summary answer: 1.Vaginal and endometrial microbiome samples are significantly different from each other with respect to (alpha-)diversity showing the endometrial community to be more polymicrobial.

What is known already: 1. The female genital tract is colonized by a continuum of microbiota, ranging from the typically more diverse, but lower-biomass, bacterial communities in the endometrium to the typically less diverse, but higher-biomass, communities in the vagina (Chen et al., 2017). In reproductive-age women, vaginal bacterial communities are mainly dominated by lactobacilli (Ravel, 2011). By contrast, the composition of the endometrial microbiome has remained less well-characterized. With the more recent introduction of next generation sequencing a more quantitative and comprehensive picture of the composition of endometrial bacterial communities has begun to emerge (Baker et al., 2018).

Study design, size, duration: 1. The study was conducted at "novum, Zentrum für Reproduktionsmedizin", Essen / Duisburg, Germany. Of 76 enrolled patients undergoing treatment,73 provided both vaginal swab and endometrial biopsy samples from the same sequencing run between February 2020 and March 2021. All analyses were carried out retrospectively. Information about pregnancy or delivery were extracted from medical records or obtained by telephone or email interviews conducted through June 2022.

Participants/materials, setting, methods: 1.Amplification of V1-V2 16S rDNA regions was carried out at "dus.ana, Düsseldorf Analytik", Germany, using the QIAseq 16S screening and regional panels. CLC Microbial Genomic Workbench was used to assess bacterial community composition, alpha diversity, and microbial community structure (PCoA). Pairs of complete corresponding vaginal and endometrial microbiota data were available for 71 patients (two patient was excluded due to too low read counts in the vaginal or the endometrial probe, respectively).

Main results and the role of chance: 1.Patients exhibiting a mean age of 35 years (range 26 – 42) and a mean body mass index (BMI) of 24,5 (range 18,8 to 38,7). 20 (28,2 %) patients were diagnosed with chronic endometritis (more than 1 plasmacyte per HPF) and 15 (21,1 %) with endometriosis. 40 study participants were found to have undergone past miscarriages, and 11 study participants were found to have given birth to 15 children.

2.Abundance analyses showed differences between vaginal and endometrial samples for the Lactobacillus sp., most pronounced for L. jensenii and L. gasserie. The group of non-lactobacilli was only slightly enlarged in the endometrial group, encompassing mainly G. vaginalis. With regard to diversity (Shannon entropy), both microbiota are significantly different (Kruskal-Wallis test). In addition, distribution of the genital microbial communities illustrated by PCoA indicated that the vaginal samples were clustered together showing variance only in one dimension. However, the endometrial samples were far away from each other and grouped very disperse.

Limitations, reasons for caution: 1.Group of infertile patients of an IVF center with different underlying clinical diagnosis studied in a retrospective setting.

Wider implications of the findings: 1.Trans-cervical sampling with a "pipelle" provides an endometrial microbiome which is obviously a more polymicrobial community - with a higher diversity, that may harbor more biological heterogeneity, and hence functionality – than the corresponding vaginal

microbiome. Further analyses studying the correlation between sequencing and clinical data are ongoing.

O-260 The influence of the vaginal microbiome on clinical outcomes in patients undergoing a frozen embryo transfer: a prospective pilot study

C. Povey[1], E. Labarta Demur[2], C. Rodríguez-Varela[3], M.C. Savash[4], D. Wells[1], K. Spath[1]

[1]*Juno Genetics UK, Research and Development, Oxford, United Kingdom*
[2]*IVI RMA Valencia, Valencia, Valencia, Spain*
[3]*IVI Foundation, IIS La Fe, Valencia, Spain*
[4]*University of Oxford, Nuffield Department of Women's and Reproductive Health, Oxford, United Kingdom*

Study question: Are Lactobacillus-dominant vaginal microbial compositions advantageous for clinical outcomes and is the specific Lactobacillus species relevant?

Summary answer: Favourable clinical outcomes are increased in patients with a Lactobacillus-dominant vaginal microbiome, particularly in those patients with microbial communities dominated by L.crispatus and L.jensenii.

What is known already: The clinical relevance of the urogenital microbiome is emerging as a topic in female reproductive health. Recent evidence suggests that the composition of the vaginal microbiome may have an impact on clinical outcomes in patients undergoing assisted reproductive treatment. A Lactobacillus-dominant microbiome (LDM), typically composed of L.crispatus, L.gasseri, L.iners or L.jensenii, is considered to be associated with favourable outcomes. In contrast, a non-Lactobacillus-dominated microbiome (NLDM), consisting predominantly of anaerobe species, may be linked to poor outcomes. The evidence surrounding this relationship is controversial and the importance of relative Lactobacillus abundance in the vagina in relation to clinical outcomes remains unclear.

Study design, size, duration: A single-centre prospective pilot study included 81 patients (mean age: 38.2) undergoing frozen embryo transfer using their own (n = 52) or donated (n = 29) oocytes. A vaginal swab was taken on the embryo transfer day and the microbiome analysed. Implantation, ongoing pregnancy and early miscarriage rates were compared between different microbiome compositions. To minimise the confounding effect of aneuploidy on clinical outcomes, a patient sub-group (n = 54) receiving donor oocytes or a euploid embryo transfer was also considered.

Participants/materials, setting, methods: Quantitative PCR was utilised to determine the relative abundance of the four predominant Lactobacillus species as well as 15 species associated with vaginal dysbiosis. Microbiome compositions were grouped according to the relative Lactobacillus abundance and patients divided into an LDM (>80%) or NLDM (<80%) group. Patients were further sub-divided into community state types (CSTs) according to the dominant species present in their sample (CST-I: L.crispatus, CST-II: L.gasseri, CST-III: L.iners, CST-V: L.jensenii and CST-IV: dysbiotic species).

Main results and the role of chance: Relative abundance of Lactobacillus was significantly higher in samples from patients achieving an ongoing pregnancy (80.7% vs. 61.7%; p = 0.05). Implantation rates were comparable between LDM and NLDM patients (66.0% and 64.3%), but the ongoing pregnancy rate showed an apparent increase in LDM patients (58.5% vs. 39.3%; p = 0.11), concomitant with a significant decrease in the miscarriage rate (11.4% vs. 38.9%; p = 0.03). Limiting the analysis to patients at low risk of aneuploidy (young donor and PGT-A cycles), Lactobacillus abundance appeared higher in patients with ongoing pregnancies (74.8% vs. 58.0%; p = 0.34). Likewise, LDM patients showed higher ongoing pregnancy (61.3% vs. 43.5%; p = 0.27) and lower miscarriage (5.0% vs. 33.3%; p = 0.06) rates, although significance was not achieved in this restricted sample. Comparison of CST groups indicated better outcomes in CST-I and CST-V compared to other groups. The ongoing pregnancy rate was significantly higher (65.7% vs. 41.3%; p = 0.04), alongside a lower miscarriage rate (8.0% vs. 32.1%; p = 0.04). When only considering patients with low aneuploidy risk, similar results were obtained (implantation rate: 78.9% vs. 57.1%, p = 0.14; ongoing pregnancy rate: 73.7% vs. 42.9%, p = 0.04; miscarriage rate: 6.7% vs. 25.0%, p = 0.21). Of note, there were no differences in baseline characteristics (age, ethnicity & BMI) or embryo morphologies between groups.

Limitations, reasons for caution: All patients were from a single fertility clinic and the study population was predominantly composed of white women. Consequently, results may not be applicable to women of different ethnicities. Patients with a low risk of aneuploid embryo transfer represented a small subgroup where meaningful statistical analysis was not always possible.

Wider implications of the findings: This study identifies a correlation between Lactobacillus species colonisation in the vagina and successful clinical outcomes, suggesting that the vaginal microbiome modulates the chances of IVF success. The results are promising, providing motivation for further, larger studies, involving more diverse populations in order to draw definitive conclusions.

O-261 The relationship of abnormal vaginal microbiome (dysbiosis of vaginal microbiome) and proinflammatory cytokines in recurrent implantation failure patients

M. Hortal[1], B. Lledo[1], J.A. Ortiz[1], A. Fabregat[1], B. Moliner[2], A. Bernabeu[2], R. Bernabeu[2]

[1]*Instituto Bernabeu, IB Biotech, Alicante, Spain*
[2]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Is there any correlation between serum cytokine levels and the composition of the vaginal microbiome in recurrent implantation failure (RIF) patients?

Summary answer: The levels of IFN-γ/IL-10 and TNF-α/IL-6 ratios are higher in patients with dysbiotic microbiome which associates with an imbalance towards inflammation between Th1/Th2 lymphocytes.

What is known already: In recent years, the development of sequencing-based technologies has enabled the evaluation of the vaginal microbiome. Studies have shown that a vaginal microbiota with less than 90% of Lactobacillus is predictive of IVF treatment outcome and suggests that dysbiosis in the reproductive tract negatively affects the reproductive outcome compared to women with a Lactobacillus-dominated microbiome.

Furthermore, it is known that pregnancy is characterized by a Th2-dominant cytokine pattern, and, in contrast, an altered Th1/Th2 ratio, and altered NK cell and macrophage numbers are more prevalent in women with RIF.

Study design, size, duration: Twenty patients were included in a retrospective study between December 2018 and May 2022. Thirteen had normal microbiome and seven had dysbiotic microbiome. In all of them, a vaginal microbiome sample was analyzed and the levels of cytokines IL-2, IL-4, IL- 6, IL-8, IL-10, VEGF, IFNγ, TNFα, IL-1α, IL-1β, MCP-1 and EGF in serum were measured. Patients with uterine malformations, uterine surgery or other known factors which may influence RIF were excluded from the analysis.

Participants/materials, setting, methods: To measure the levels of the different cytokines, a sandwich immunoassay with specific antibodies for the cytokines IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, IFNγ, TNFα, IL -1α, IL-1β, MCP-1 and EGF were used. Vaginal microbiome was analyzed by mass sequencing of the V3V4 region of 16S rRNA. The statistical analysis was performed with R Statistical Software, version 4.0.3 and the bioinformatic analysis of vaginal microbiome was performed using QIIME2 and MicrobiomeAnalyst packages.

Main results and the role of chance: For the ratios between cytokines produced by Th1 lymphocytes and Th2 lymphocytes, we observe that levels of IFN-γ/IL-10 (p = 0,043) and TNF-α/IL-6 (p = 0,021) ratios are higher in patients with dysbiotic microbiome, which have an imbalance towards inflammation.

Comparing levels of cytokines with respect to alpha diversity, no differences are observed either individually or in the ratios between Th1/Th2 cytokines. However, the multivariate model that predicts alpha diversity (p = 0.037; AIC=20.734) does consider the IFN-γ/IL-10 and TNF-α/IL-6 aforementioned ratios. Alpha diversity, in turn, is higher in vaginal samples

from patients with dysbiotic microbiome ($p = 0.003$). Regarding beta diversity, it is also higher in patients with altered microbiome ($p = 0.007$).

Considering the relative abundance of each bacteria, we can predict the levels of the aforementioned ratios: for TNF-α/IL-6 ratio, the multivariate model reaches 91.37% of prediction including the relative abundance of *Burkholderia, Chryseobacterium, Enterococcus, Escherichia, Gemella, Herbaspirillum, Negativicoccus* and *Staphylococcus*. For IFN-γ/IL-10 ratio, the multivariate model reaches 87,65% of prediction including *Aerococcus, Burkholderia, Escherichia, Herbaspirillum, Megasphera, Pseudomonas, Ralstonia* and *Staphylococcus*. It is worth noting the absence of *Lactobacillus* in these models, which suggests that the relative abundance of some pathogenic bacteria is what alter the production of cytokines, not the lower relative abundance of *Lactobacillus*.

Limitations, reasons for caution: The inherent limitations of a retrospective study design and a limited sample size. In addition, cytokine levels were measured in serum and not in vaginal fluid. Additional studies including a metagenomic approach might be able to determine functional groups of bacteria for analysis.

Wider implications of the findings: These results indicate that pathogenic bacteria, such as Burkholderia and Staphilococcus, which modify cytokine levels and cause inflammation, may also induce an imbalance in the Th1/Th2 ratio. When the vaginal microbiome is altered, the administration of antibiotics or probiotics may improve the immunologic environment, thus, avoiding the use of immunosuppressants.

[5]*Copenhagen University Hospitals - Rigshospitalet and Hvidovre Hospital, Recurrent Pregnancy Loss Unit- The Capital Region- Fertility Clinic- Rigshospitalet and Hvidovre Hospital, Copenhagen Ø, Denmark*

Study question: Is the vaginal or faecal microbiome different between primary RPL (pRPL) and secondary RPL (sRPL) patients, and is it related to reproductive outcome after referral?

Summary answer: Before pregnancy, the vaginal microbiome differed between pRPL and sRPL, and the faecal microbiome was altered in those who did not achieve pregnancy after follow-up.

What is known already: RPL is a heterogeneous condition leaving 50% of the couples without any known risk factors after the initial diagnostic workup. The microbiome of the reproductive tract seems to be an essential factor in women's health, including pregnancy loss. Only a few studies have investigated the vaginal microbiome in women with RPL and found dysbiosis with a decrease in *Lactobacillus crispatus*. To our knowledge, the faecal microbiome in women with RPL has never been investigated.

Study design, size, duration: A prospective cohort study including 106 women referred with unexplained RPL between 04/2018 and 12/2019. Patients were routinely screened for established risk factors as recommended in the ESHRE RPL guideline. Exclusion criteria were >40 years, >1 shared child, the use of antibiotics, antimycotics and antiviral medication within the past two weeks, known chromosomal aberrations and major uterine malformations. Follow-up ranged between 12-31 months.

Participants/materials, setting, methods: The women were referred with a minimum of three unexplained consecutive pregnancy losses (64 pRPL and 42 sRPL) to the tertiary Recurrent Pregnancy Loss Unit at Copenhagen University Hospital (Rigshospitalet and Hvidovre Hospital), Denmark. Vaginal and faecal samples were collected before pregnancy and shot-gun sequenced on a DNBSEQ-G400 sequencer (MGI) using the high-throughput sequencing set (PE150 1000016952; MGI).

Main results and the role of chance: The beta diversity in the vaginal samples was significantly different ($p = 0.001$) between pRPL and sRPL, with *Lactobacillus crispatus* dominating more women with pRPL compared to sRPL who were dominated by *Lactobacillus iners*. Overall, twenty-nine patients (27.3% of the cohort) had vaginal dysbiosis defined as < 60% Lactobacillus spp. with no significant difference between pRPL and sRPL (vaginal dysbiosis in 21.8% vs. 35.7%, $p = 0.118$). During follow-up, 93 (87.7%) patients achieved pregnancy of which 50 (53.8%) resulted in a live birth and 43 (46.2%) in another pregnancy loss. There were no differences in age, BMI, alpha or beta diversity in the vaginal samples between the live birth group and pregnancy loss group. In the live birth group, 11 patients (22.0%) had vaginal dysbiosis compared with 32.1% of the rest of the cohort, $p = 0.242$. Ninety-three of 106 women collected a faecal sample at home after the first consultation and there was a significant difference in both alpha diversity ($p = 0.014$), beta diversity ($p = 0.05$) and richness ($p = 0.001$) between women who achieved pregnancy compared with those who did not conceive after follow-up.

Limitations, reasons for caution: Patients with recurrent pregnancy loss constitute a heterogenic population, which underlines the importance of subgroup comparisons such as pRPL and sRPL.

Wider implications of the findings: These findings underline the role of an altered vaginal and faecal microbiome as a potential risk factor for RPL. In-depth knowledge about the altered microbiome compositions in these patients can contribute to the generation of future treatment strategies and potentially improve patient care.

O-263 Effect of clindamycin and a live biotherapeutic containing lactobacilli on the reproductive outcomes of IVF patients with abnormal vaginal microbiota: a double-blind, placebo-controlled multicentre trial

T. Haahr[1], J.S. Jensen[2], B. Alsbjerg[1], H.O. Elbaek[1], R. Laursen[1], M. Brix[1], A. Mikkelsen[1], T. Pedersen[2], L. Praetorius[3], A. Pinborg[4], N. Freiesleben[3], P. Humaidan[1]

[2]*Statens Serum Institute, Reproductive microbiology, Copenhagen, Denmark*
[3]*Hvidovre Hospital, Fertility Clinic, Copenhagen, Denmark*
[4]*Fertility Clinic, Rigshospitalet- Copenhagen University Hospital, Copenhagen, Denmark*

Study question: Does treatment of abnormal vaginal microbiota improve the reproductive outcomes of IVF patients?

Summary answer: Data is being analysed and will be presented at ESHRE 2023.

What is known already: An increasing number of studies reported an association between abnormal genital tract microbiota and adverse reproductive outcomes in IVF patients. One hypothesis could be that vaginal microbiota ascend to the endometrium where the microbiota hampers implantation. To the best of our knowledge, this is the first study powered to investigate causality between abnormal genital tract microbiota - in this study defined by a bacterial vaginosis like vaginal microbiota - and clinical pregnancy rate in IVF patients.

Study design, size, duration: Double-blind, placebo-controlled multicentre trial in IVF patients diagnosed with abnormal vaginal microbiota and subsequently randomised into three parallel groups 1:1:1. The first group received clindamycin 300 mg ×2 daily for 7 days followed by vaginal *Lactobacillus crispatus* until the clinical pregnancy scan. The second group received clindamycin and placebo, whereas the third group received placebo/placebo. A total of 1518 patients were screened, and 338 patients were randomised. The study duration was from 2017 to 2023.

Participants/materials, setting, methods: IVF patients with any cause of infertility embarking on their first, second or third IVF stimulation cycle or embryo transfer were approached for inclusion. At a minimum 12 days prior to embryo transfer, patients were screened for abnormal vaginal microbiota defined by a qPCR assay, targeting high quantitative loads of *Fannyhessea vaginae* and *Gardnerella spp*. Patients were excluded if they had intrauterine malformations like polyps, septum, and fibroma.

Main results and the role of chance: Data and safety monitoring board has decided not to open the randomization code yet. The final dataset is being completed. Data is being analysed and will be presented at ESHRE 2023.

Limitations, reasons for caution: Data is being analysed and will be presented at ESHRE 2023.

Wider implications of the findings: The present drug intervention study used clindamycin and a live biotherapeutic containing *Lactobacillus crispatus*. The results of the study could have a worldwide important clinical impact on daily IVF practice as currently there is no evidence that screening and treating IVF patients with abnormal vaginal microbiota improves the reproductive outcome.

[5]Amager/Hvidovre Hospital, Department of Clinical Microbiology, Copenhagen University Hospital Hvidovre- DK-2650, Denmark
[6]Amager/Hvidovre Hospital, Department of Obstetrics and Gynecology- The Fertility Clinic, Copenhagen University Hospital Hvidovre- DK-2650, Denmark

Study question: Can vaginal microbiota transplantation with shotgun-verified eubiotic vaginal microbiome over three menstrual cycles, convert vaginal dysbiosis to eubiosis in healthy women?

Summary answer: The RCT is ongoing until it is by March 2023. Results will be ready for presentation at EHSRE conference.

What is known already: Vaginal dysbiosis covers imbalances in the vaginal flora, caused by the composition of bacteria, viruses, and vaginal fungi. A large proportion of women who have vaginal dysbiosis do not experience any symptoms. Dysbiosis occurs in about 16-20% of all women. Vaginal dysbiosis is associated with infertility, euploid pregnancy loss, preterm labour or bacterial vaginosis. Treatment of vaginal dysbiosis consists of antibiotic treatment, and/or probiotics. Vaginal transplantation with eubiotic vaginal bacterial flora in combination with antibiotics has successfully been performed in four out of five recipients in an earlier study, but no study has been performed without use of antibiotic pretreatment.

Study design, size, duration: Randomized, controlled, double-blinded trial with a randomization ratio 3:1 to receive either a eubiotic microbiome transplant or placebo. 320 healthy women between 18 and 40 years, was enrolled for screening of vaginal dysbiosis. 30 donors with a eubiotic vaginal microbiome and 48 recipients with a dysbiotic microbiome were identified. The trial began in June 2021 and will end in March 2023

Participants/materials, setting, methods: Vaginal microbiome composition was assed by next-generation ShotGun sequencing. To qualify as donor bacterial DNA from a vaginal swab had to show a bacterial composition of at least 80% lactobacilli and less than 5% pathogenic bacteria. To qualify as recipient vaginal microbiome composition should be with at least 20% pathogenic bacteria and no more than 10% lactobacilli. The recipient could have up to three attempts of VMT treatments with a follow-up period of 6 months.

Main results and the role of chance: We expect the RCT to end in March 2023, and the results of this trial will be presented at the ESHRE annual meeting . If we can show engraftment of a eubiotic microbiome transplant without the use of pre-treatment with antibiotics it could be a potential treatment of vaginal dysbiosis.

Limitations, reasons for caution: As this is the first VMT without antibiotic pretreatment we did not have reliable data for our power calculation and a negative result may be due to lack of statistical power.

Wider implications of the findings: Effective treatments for vaginal dysbiosis are urgently needed and VMT may be one such treatment strategy.

O-265 Increased CD8+ T-cell exhaustion due to high NKG2A/HLA-E engagement and IL-15 induction in adenomyosis

X. Jiao[1], W. Liu[2], S. Sheng[3], C. Zhu[1], F. Wang[3]

[1]Center for Reproductive Medicine- Shandong University, None, Jinan, China
[2]Shandong Provincial Hospital- Shandong University, Department of Obstetrics and Gynecology, Jinan, China
[3]Shandong Provincial Hospital- Shandong First Medical University, Department of Obstetrics and Gynecology, Jinan, China

Study question: Is there dysregulation of immune cells in the local uterine microenvironment of patients with adenomyosis? If any, what's the underlying mediators and mechanisms?

Summary answer: Increased $CD8^+$ T-cell exhaustion due to enhanced HLA-E/NKG2A engagement and IL-15 induction in ectopic adenomyotic lesions existed in human patients and mice models with adenomyosis.

What is known already: The immunological dysfunction has long been considered in the pathogenesis of adenomyosis. However, high heterogeneity in immune cell alterations and contradictory results were reported due to the technique limitation of immunohistochemistry mainly used in previous studies. A comprehensive picture of the dysregulation of immune cells in the local uterine microenvironment of patients with adenomyosis is still lacking. Specially, increased number of $CD8^+$ T cells have been reported in adenomyotic patients, whether functional deficiency of $CD8^+$ T cells may contribute to the abnormal accumulation and residency of ectopic endometrial cells at pathological sites remains unknown.

Study design, size, duration: The paired ectopic lesions and eutopic endometrium from 80 patients with adenomyosis, and normal endometrium and myometrium from 62 patients with uterine myoma (controls) were collected between 2021 to 2022. Mice models with adenomyosis by neonatal tamoxifen treatment were established for experiments in 2022.

Participants/materials, setting, methods: The alteration of immune subsets, NKG2A expression, exhausted phenotypes and $CD8^+$ T-cell dysfunction by flow cytometry, the expression/localization of HLA-E and IL-15 by

immunohistochemistry were investigated in uterine tissues of patients and mice models with adenomyosis. $CD8^+$ T cells were sorted, and in-vitro cultured with recombinant human transforming growth factor-β (rhTGF-β) or rhIL-15 to determine the NKG2A expression. Correlation analyses were conducted for association between immune disturbances and disease severity (dysmenorrhea, local/diffuse lesion, CA125 level).

Main results and the role of chance: We found that an increase in $CD8^+$ T cell number was the predominant alteration in ectopic lesions in patients with adenomyosis, and it was significantly associated with the severity of adenomyosis. For $CD8^+$ T cells in adenomyotic lesions, the expression of NKG2A was positively correlated with CD94 expression, and CD94/NKG2A mainly enriched on $CD103^+$ tissue resident $CD8^+$ T subsets. The $NKG2A^+CD8^+$ T cells showed exhausted phenotypes characterized by co-expression of multiple immune inhibitory molecules (PD1, LAG3, TIM3, and TOX) and decreased degranulation capability demonstrated by reduced expression of perforin, granzyme B, and CD107. Importantly, the exhausted $NKG2A^+CD8^+$ T-cell subset was associated with disease severity and was significantly increased in ectopic uterine tissues of human patients and mice models with adenomyosis. The expression of NKG2A on $CD8^+$ T cells was markedly upregulated by exogenous rhIL-15 but not rhTGF-β treatment. Additionally, we also found increased co-expression of IL-15 and the NKG2A ligand HLA-E on the glandular epithelial cells, where the $NKG2A^+CD8^+$ T cells were closely distributed around the gland, in ectopic adenomyotic microenvironment of patients and mice models with adenomyosis.

Limitations, reasons for caution: The control uterine samples were collected from patients with uterine myoma. Although they were pathologically confirmed as normal, the potential effects are unknown and cannot be excluded. Further studies in larger independent populations and exploration on the functional significance of $CD8^+$ T-cell exhaustion in adenomyosis pathogenesis is warranted.

Wider implications of the findings: Our study reveals a previously unrecognized role for $CD8^+$ T-cell exhaustion in the pathogenesis of adenomyosis and suggests that therapeutic interventions targeting and reinvigorating exhausted $CD8^+$ T cells by NKG2A blockade may be beneficial for patients with adenomyosis.

O-266 Anti-angiogenic therapy as treatment for adenomyosis in mice

M. Harmsen[1], L. Juffermans[1], M. Kroon[1], A. Griffioen[2], J. Huirne[1]

[1]*Amsterdam UMC, Obstetrics and Gynecology, Amsterdam, The Netherlands*
[2]*Amsterdam UMC, Medical Oncology- Angiogenesis Laboratory, Amsterdam, The Netherlands*

Study question: What is the effect of anti-angiogenic therapy on adenomyosis in mice

Summary answer: Commencing treatment at six weeks with angiogenesis inhibitor axitinib successfully reduced the severity of adenomyosis by approximately 50% at 9 weeks.

What is known already: Adenomyosis is a gynecological disorder characterized by abnormal uterine bleeding, dysmenorrhea, pelvic pain and subfertility. Increased expression of angiogenic markers, as well as increased microvascular density (MVD) in adenomyosis suggest a pivotal role for angiogenesis in the pathophysiology of adenomyosis, which presents an opportunity for treatment.

Study design, size, duration: The effect of angiogenesis inhibition was studied in a tamoxifen-induced adenomyosis mouse model. 102 Mice received oral treatment with axitinib 3 mg/kg ('dose I/AX3 treatment group', n = 34), axitinib 25 mg/kg ('dose II/AX25 treatment group' n = 34), or with vehicle-only ('placebo group', n = 34) from week 6 until week 9. After termination of the mice at week 9, all uteri were analyzed for the presence of adenomyosis.

Participants/materials, setting, methods: The prevalence and severity of adenomyosis were assessed by; (i) grade of adenomyosis (0/1/2/3), based on the depth of endometrial gland infiltration into the myometrium in H&E-stained sections, (ii) percentage of adenomyosis-affected tissue in vimentin-stained sections and (iii) degree of myometrium that is affected in α-SMA-stained sections. The adenomyosis severity index was calculated by multiplying mean grade/mouse with the percentage affected surface area. Changes in angiogenesis-related gene expression were evaluated using real-time quantitative PCR.

Main results and the role of chance: 101 mice completed adenomyosis induction and could be analyzed. The prevalence of adenomyosis was 30/33 (90.0%) in dose I (3mg/kg), 29/34 (85.3%) in dose II (25mg/kg) and 30/34 (88.2%) in placebo treated mice (p=0.78). The prevalence of high grade (2/3) adenomyosis was significantly lower in mice treated with axitinib dose II (N = 19, 55.9%) than in the placebo group (N = 27, 79.4%, $p<0.05$). The grade of adenomyosis per mouse after treatment was 0.7 point lower in the groups treated with axitinib dose I and dose II, than in the placebo treated group (dose I and II both median of 1.0 compared to 1.7, $p < 0.05$). The adenomyosis severity index was reduced by 48% in the axitinib-treated groups (dose I $p<0.05$). In the placebo-treated group, the myometrium adjacent to the affected site (as a marker for hypertrophy) was thicker in the placebo- than in the axitinib-treated groups. There were no signs of fibrosis. MVD was reduced in myometrium of dose I treated mice by 14% compared with Ax25-treated mice ($p<0.05$), as well as compared to 6-week-old tamoxifen-treated mice ($p<0.05$). Expression of angiogenic growth factors and their receptors was markedly reduced in the dose I and II axitinib-treated groups compared to the placebo-treated group.

Limitations, reasons for caution: Limitations of this study include the uncertainty on the optimal timing to start treatment, and the assessment of the presence and severity of adenomyosis. Further research should focus on commonality among different angiostatic drugs, as well as the method and timing of application.

Wider implications of the findings: Since there is currently no treatment option for premenopausal women who wish to retain their uterus and their fertility, treatment with an angiogenesis inhibitor might provide a solution. The major requirement in further development of anti-angiogenesis therapy is a safety and side-effect profile tolerable for this population.

Study question: Description of uterine contractility characteristics in adenomyosis patients compared to healthy controls and according to degree of dysmenorrhoea measured by quantitative 2D transvaginal ultrasound (TVUS).

Summary answer: Women with adenomyosis show differences in uterine contraction patterns (frequency, amplitude, velocity, and contraction coordination) compared to healthy controls and depending on degree of dysmenorrhoea.

What is known already: The natural contraction pattern of the uterus changes throughout the menstrual cycle in response to cyclic changes in hormones. In abnormal uteri, such as adenomyotic uteri, this response may be different. Adenomyosis can cause dysmenorrhoea, menorrhagia, dyspareunia, and subfertility. These symptoms could be explained by different contraction patterns of the uterus, however, this has not yet been objectively quantified due to the absence of a suitable measurement tool. Recently, speckle-tracking

and strain analysis of 2D TVUS was used to assess differences in contraction coordination, frequency, velocity, and direction, depending on the phase of the menstrual cycle in healthy women.

Study design, size, duration: This study is part of an ongoing multi-centre prospective observational cohort study investigating uterine contractility in TVUS recordings. Our study includes the TVUS recordings of 31 women with adenomyosis and 106 women with healthy uteri. Patients were included in 3 centres from 2017 to 2023 (Netherlands, Greece, Italy).

Participants/materials, setting, methods: 31 women with sonographic suspicion of adenomyosis and 106 women with healthy uteri with natural menstrual cycles were included. Uterine contraction frequency, amplitude, velocity, and coordination were assessed by applying a dedicated speckle tracking and strain analysis to 2-4-minute TVUS recordings in midsagittal section. Degree of dysmenorrhoea was measured according to visual analogue score (VAS). Women with suspicion of adenomyosis were compared to women with healthy uteri according to the phase of their menstrual cycle.

Main results and the role of chance: Age, BMI, parity and uterus volume were significantly higher in the women with adenomyosis compared to the healthy controls ($p < 0.05$). Uterine contractility differed between women with adenomyosis and healthy controls during the periovulatory phase, revealing lower frequency (1.50 ± 0.25 vs. 1.75 ± 0.35, $p = 0.031$), higher amplitude (0.076 ± 0.039 vs. 0.046 ± 0.018, $p = 0.001$), and lower velocity (0.64 ± 0.18 vs. 0.84 ± 0.22, $p = 0.020$) of uterine contractions in the group with adenomyosis patients. In the late luteal phase, women with adenomyosis showed higher amplitude (0.050 ± 0.02 vs. 0.035 ± 0.01, $p = 0.039$) and lower velocity (0.51 ± 0.11 vs. 0.72 ± 0.16, $p = 0.032$) than the healthy controls. During menstruation, women with adenomyosis showed a trend towards higher contraction amplitude (0.044 ± 0.01 vs. 0.037 ± 0.01, $p = 0.051$) compared to healthy controls. During the menstrual, periovulatory and late luteal phase, women with adenomyosis showed reduced contraction coordination ($p = 0.047$, $p = 0.015$ and $p = 0.011$, respectively) compared to healthy controls. Increased dysmenorrhoea (VAS score) in overall adenomyosis patients was associated with lower contraction velocity ($p = 0.043$) and a tendency towards lower frequency ($p = 0.160$) and higher amplitude ($p = 0.154$).

Limitations, reasons for caution: No sub-analysis was done to assess effects of additional adenomyosis characteristics (i.e. adenomyosis severity, adenomyosis type, adenomyosis location). Women with extensive adenomyosis were not included due to impossibility to perform analysis of ultrasound images. Women with adenomyosis were older, had higher BMI and larger uterus volumes than healthy controls.

Wider implications of the findings: Uterine contractility differs between patients with adenomyosis versus healthy women throughout the menstrual cycle. More dysmenorrhoea in adenomyosis patients was also associated with a different contractility pattern. This suggests an aetiological mechanism for the clinical presentation of adenomyosis (i.e. dysmenorrhoea and subfertility) and presents potential therapeutic markers.

O-268 Presence of adenomyosis impairs clinical outcomes in women undergoing frozen embryo transfer

N. Sachs Guedj[1], B. Coroleu[1], M.A. Pascual[1], I. Rodríguez[1], N.P. Polyzos[1]

[1]*Dexeus University Hospital, Department of Obstetrics- Gynecology- and Reproduction, Barcelona, Spain*

Study question: Does the presence of adenomyosis impact the clinical outcomes of patients undergoing frozen embryo transfer (FET)?

Summary answer: Presence of adenomyosis is associated with higher miscarriage and lower clinical pregnancy and live birth rates. GnRH agonist pretreatment does not increase clinical outcomes.

What is known already: Presence of adenomyosis among pregnant patients has been associated with a higher incidence of miscarriage and pregnancy complications. Although the role of adenomyosis in women undergoing in vitro fertilization (IVF) has been investigated in several studies demonstrating a potential detrimental effect on live birth rates following IVF, most of them were small studies in which adenomyosis diagnosis was not confirmed based on solid ultrasonographic criteria. Considering the fragmented evidence up to date, we decided to perform a large retrospective study including women with adenomyosis undergoing FET which has been confirmed based on solid ultrasonographic criteria.

Study design, size, duration: Retrospective cohort study of 3503 patients undergoing their first cycle of blastocyst frozen transfer in a university-affiliated fertility center between January 2017 and December 2021.

Participants/materials, setting, methods: Overall, 3503 patients undergoing their first blastocyst frozen transfer through a hormonal replacement (HRT) FET cycle. Patients were categorized as adenomyosis when fulfilling to the Morphological Uterus Sonographic Assessment (MUSA) criteria and as non-adenomyosis when no-adenomyosis was identified. Among them 140 women had a confirmed diagnosis of adenomyosis based on MUSA criteria. Clinical information was retrospectively collected from medical records.

Main results and the role of chance: Comparisons between adenomyosis and non-adenomyosis groups revealed similar baseline characteristics in terms of patients' weight, parity, smoking status, and age. Similarly, endometrial thickness and mean serum progesterone levels the day before FET as well as the number of embryos transferred were comparable between groups.

Adenomyosis patients were more likely to proceed with a deferred FET (freeze-all protocol) as compared with no-adenomyosis women ($p = 0.002$) and were significantly more likely to be treated with GnRH agonist pre-treatment (2 injections) ($P < 0.001$).

Multivariable logistic regression, adjusting for age, autologous or donor oocytes, PGT-A, deferred FET, serum progesterone levels the day before FET, GnRH agonist pre-treatment, number of embryos transferred, and adenomyosis, demonstrated that the use of GnRH agonist protocol did not affect miscarriage, clinical pregnancy rate or live birth rate.

However, the presence of adenomyosis significantly decreased clinical pregnancy rates (OR 0.62, 95% CI: 0.39-0.98, $P = 0.040$) and live birth rates (OR 0.46, 95% CI: 0.27-0.75, $P = 0.003$) and significantly increased miscarriage rates (OR 2.13, 95% CI 0.98-4.37, $p = 0.045$). PGT-A was the only factor associated with a significative reduction in miscarriage rate.

Limitations, reasons for caution: The main limitation of this study is the single-center retrospective approach. Furthermore, due to the limited number of cases with adenomyosis focal and diffuse adenomyosis were analyzed together although this may be clinically distinct entities.

Wider implications of the findings: The results of this study demonstrate that presence of adenomyosis has significant negative impact on the clinical outcomes of patients undergoing FET. Future prospective studies are needed to create a consensus on the optimal ET technique for these patients.

O-270 Does the 'freeze all' strategy improve the chances of birth in the presence of adenomyosis?

M. Bourdon[1], L. Fouque Gadol[1], C. Maignien[1], C. Bordonne[2], A. Chargui[3], L. Marcellin[1], L. Maitrot Mantelet[1], C. Charles[1], P. Santulli[1]

[1]Cochin - Port Royal - Hôpitaux Universitaires Paris Centre, Service de Gynécologie Obstétrique II and Reproductive Médicine Professor Chapron, Paris Cedex 14, France
[2]Cochin - Hotel Dieu - Hôpitaux Universitaires Paris Centre, Service de Radiologie, Paris, France
[3]Cochin - Port Royal - Hôpitaux Universitaires Paris Centre, Service de biologie et médecine de la reproduction, Paris Cedex 14, France

Study question: Does the freeze all strategy improve cumulative live birth rates in infertile women affected with adenomyosis?

Summary answer: The freeze all strategy in adenomyosis-affected women is associated with significantly higher cumulative live birth rates.

What is known already: Controlled ovarian stimulation enhances the efficacy of assisted reproductive technology (ART) by permitting multiple-oocyte yields, but also may alter endometrial receptivity by an earlier endometrial development which could in turn contribute to diminished pregnancy chances. Technical improvements in vitrification made deferred frozen-thawed embryo transfer (freeze –all strategy) a feasible alternative to fresh embryo transfer (ET). In adenomyosis, the eutopic endometrium is abnormal and its functional alterations are seen as likely to alter the quality of endometrial receptivity. One question in the adenomyosis ART-management is to know whether a freeze all strategy could lead to an increase in reproductive outcomes.

Study design, size, duration: This cohort study conducted in a tertiary care university hospital included adenomyosis-affected women undergoing blastocyst embryo transfer following in vitro fertilization / intracytoplasmic sperm injection (IVF/ICSI) between 01/01/2018 to 31/11/2021. The diagnosis of adenomyosis was based on imaging criteria (e.g. transvaginal ultrasound and/or magnetic resonance imaging).

Participants/materials, setting, methods: Women who underwent a freeze all strategy were compared to those who underwent a fresh ET strategy. Statistical analyses were conducted using univariate and multivariate logistic regression models. The primary outcome was the cumulative live birth rate (LBR).

Main results and the role of chance: A total of 306 women were included in the analysis: 111 in the fresh ET group and 195 in the freeze all group. The phenotype of adenomyosis (internal diffuse adenomyosis, external focal adenomyosis and adenomyomas) was not significantly different between the two groups. The cumulative live birth rate was significantly increased in the freeze all group compared to the fresh ET group [86 (44.1%) vs. 34 (30.6%), $p = 0.020$]. The cumulative OPR [89 (45.6%) versus 37 (33.3%), $p = 0.035$] and the cumulative CPR [122 (62.6%) vs. 53 (47.7%), $p = 0.011$] were significantly higher in freeze all group compared to the fresh group, whereas the early miscarriage rate was not significantly different between the two groups. After multivariate logistic regression analysis, the freeze all strategy in women with adenomyosis was associated with a significant increase in the live birth rate as compared to fresh ET (OR = 1.85; 95% CI = 1.06 – 3.24; $p = 0.031$).

Limitations, reasons for caution: This analysis consists in a retrospective cohort study. The inclusion of patients from a referral center specialized in the management of adenomyosis and endometriosis could constitute a selection bias, as these women may have had particularly severe forms of adenomyosis.

Wider implications of the findings: The freeze all strategy could be an attractive option to increase ART success rates, in adenomyosis-affected womenundergoing IVF/ICSI.

O-271 Application of HyFoSy in the assessment of fallopian tube patency compared to HyCoSy and HS; results of a systematic review and meta-analysis

E. Tsakos[1,2], E.M. Xydias[1,2], V. Emmanouil[2,3], M. Koutini[2,3], A. Ntanika[2,4], M. Prior[5], K. Lykeridou[6], I. Sarris[7], A.C. Ziogas[2,8]

Study question: To assess whether Hystero-salpingo-Foam Sonography (HyFoSy) is an effective and feasible alternative to X-ray Hystero-Salpingo-Graphy (HSG) and Hystero-salpingo-Contrast Sonography (HyCoSy) in fallopian tube patency assessment.

Summary answer: HyFoSy demonstrated significantly superior diagnostic sensitivity and specificity compared to HyCoSy, however only demonstrated minimal diagnostic agreement with HSG.

What is known already: Tubal pathology is a contributing factor in up to 35% of infertility cases, a fact which renders accurate and clinically applicable tubal patency assessment a vital component of the infertility workup. Currently, the most widely utilized methods of assessment are HyCoSy and HSG, which, while effective, do possess certain disadvantages. HyFoSy is an alternative to the aforementioned assessment test, utilizing a specially developed contrast agent, which may offer comparable diagnostic efficacy without the associated disadvantages of the other two methods.

Study design, size, duration: Relevant studies were systematically searched for in the Scopus, Pubmed and Web of Science online peer-reviewed databases. The resulting studies were systematically assessed based on pre-established inclusion criteria (PICOS format) according to the PRISMA algorithm for systematic reviews. The included studies were assessed for risk of bias using a modified version of the QUADAS-2 tool and relevant data was extracted and meta-analysis of diagnostic performance data was conducted.

Participants/materials, setting, methods: This analysis included data from 5 studies and 1433 patients, with 2336 tubes being eligible for inclusion. Data extracted regarding primary outcomes were true positive, false positive, false negative and true negative number of patients for studies that used a reference test and sensitivity and specificity could be calculated. For studies that assessed inter-method agreement, raw data on the number of patients with method agreement and disagreement was extracted and Cohen's k values were calculated.

Main results and the role of chance: With regard to HyFoSy and HyCoSy comparison, pooled sensitivity was 87% and 69% respectively, with the difference being statistically significant ($p = 0.037$), while pooled specificity was 95% and 85% respectively, with the difference being statistically significant ($p < 0.001$). Regarding the HyFoSy and HSG comparison, the pooled Cohen's k statistic resulting from the meta-analysis was 0.39 ; this is interpreted as fair to minimal overall diagnostic agreement between HyFoSy and HSG. Regarding procedure-associated patient pain, HSG was 6.5 times more painful (OR = 6.57, CI 95% 3.11–13.89) compared to HyFoSy and the former was graded at 5.4 ± 2.5 on a 10-point scale compared to the latter that was graded at 3.1 ± 2.2 ($p < 0.001$), a difference that was statistically significant.

Limitations, reasons for caution: The small number of available comparative studies on HyFoSy, the lack of studies that used a reference standard for the comparison of HyFoSy to HSG and the observed statistical heterogeneity, may have introduced a degree of bias in the results if this analysis.

Wider implications of the findings: HyFoSy, being less painful than HSG and more reliable in diagnosing patency, may be applicable as a first line diagnostic test, with HSG reserving its value in the evaluation of abnormal and/or unclear results as a second line test.

O-272 Oral administration of antioxidants can support follicle survival in xenografted human ovarian tissue

H.Ø. Olesen[1], C. Subiran Adrados[1], A.T. Pedersen[2], S.G. Kristensen[1]

[1]University Hospital Copenhagen, Laboratory of Reproductive Biology, Copenhagen 2100, Denmark
[2]University Hospital Copenhagen, Department of Gynaecology- Fertility Clinic, Copenhagen 2100, Denmark

Study question: Can oral administration of antioxidants improve follicle survival in human ovarian tissue through reduction of oxidative stress in a xenotransplantation model?

Summary answer: Daily oral administration of antioxidants for 7 days post-transplantation had a positive effect on follicle survival in grafted human ovarian tissue.

What is known already: Today cryopreservation and autotransplantation of ovarian tissue is an established fertility preservation method in many centres. Hundreds of live births have been achieved but the efficacy of this procedure is hampered by a critical loss of follicles following transplantation. The ovarian tissue is subjected to hypoxia and ischemia postoperative which leads to oxidative damage in the tissue. Postoperative supplementation with antioxidants has been shown to decrease oxidative stress in transplanted ovarian tissue and increase follicle survival, however, these results were mainly obtained through intraperitoneal injections to host animals. Oral administration of antioxidants could be a better alternative for clinical application.

Study design, size, duration: Pieces of frozen-thawed ovarian cortex tissue (total of 56) from 12 women were transplanted to immunodeficient mice in a short- and long-term xenograft study, for 7 and 28 days respectively. In each study the mice were administered daily doses of hazelnut cream (control group) for 7 days post-transplantation or hazelnut cream containing either 150 mg/kg N-acetylcysteine (NAC) or FERTILIX (containing Vitamin E, D and C, Mixed Tocopherols and Tocotrienols, Lycopene, and Coenzyme Q10).

Participants/materials, setting, methods: Cryopreserved ovarian tissue was donated by 12 women undergoing ovarian tissue cryopreservation at Copenhagen University Hospital. Grafts were retrieved after 7 and 28 days of xenografting and histologically processed for follicle counts, immunohistochemistry, and qPCR analysis. The number of surviving follicles and ovarian graft volume were evaluated histologically after 7 and 28 days xenografting. Gene expression analysis of antioxidant defence markers (*Sod1*, *Hmox* and *Catalase*) and angiogenic factor *Vegfa* were performed after 7 days xenografting.

Main results and the role of chance: After 7 days xenografting, the follicle density was similar for all groups (control group: 33.03 ± 14.85 (mean ± SEM) follicles/mm^3; NAC-group: 26.34 ± 10.54 follicles/mm^3, FERTILIX-group: 35.12 ± 10.88 follicles/mm^3). However, the NAC- and FERTILIX-group had a 3- and 3.7-fold increase in follicle density respectively compared to the control group. However, after 28 days of xenografting there was a higher density of surviving follicles in both antioxidant groups, compared to control (control group: 9.51 ± 2.9 follicles/mm^3; NAC-group: 14.9 ± 6.02 follicles/mm^3, FERTILIX-group: 14.43 ± 5.83 follicles/mm^3), which resulted in a 3.2-fold increase in follicle density in the NAC-group and 2.4-fold increase in the FERTILIX-group compared to the control group. The findings were not statistically significantly different in either the 7 days or 28 days study ($p = 0.7072$; $p = 0.5691$). The relative gene expression of the antioxidant defence genes *Hmox* and *Catalase* was overall like the control for all treatment groups after 7 days xenografting, but for *Sod1* the expression was significantly lower for the NAC- and FERTILIX-group compared to the control group ($p = 0.0407$; $p = 0.0255$). For *Vegfa* the expression was similar overall and not significantly different from the control group ($p > 0.05$).

Limitations, reasons for caution: The distribution of follicles in human ovarian cortex is highly heterogeneous and can vary tremendously between cortex pieces from the same woman and between patients. Statistically significant results were not obtained for the follicle data in the current study; thus, the conclusions should be interpreted with caution.

Wider implications of the findings: Oral administration of antioxidants had a positive effect on follicle survival in xenotransplanted human ovarian tissue. These findings provide a step toward potential clinical administration of antioxidants like NAC or FERTILIX postoperative of ovarian tissue transplantation, which could improve follicle outcomes in a feasible way for the patient.

O-273 Impact of ovarian tissue transplantation on extracellulaire matrix remodelling

M.C. Chiti[1], R. Masciangelo[2], G. Courtoy[3], J. De Miranda Vasconcellos Vilela[2], C. Amorim[2]

[1]*Cliniques Universitaires Saint Luc, IVF laboratory, Brussels, Belgium*
[2]*Université Catholique de Louvain, Pole de Recherche en Gynecologie, Bruxelles, Belgium*
[3]*Université Catholique de Louvain, IREC Imaging Platform, Bruxelles, Belgium*

Study question: Does ovarian tissue transplantation affect ovarian extracellular matrix (ECM) components?

Summary answer: Ovarian tissue transplantation affects ECM components in a time- and spatial-dependent manner

What is known already: Human ovarian ECM is subjected to a specific pattern of remodeling during woman's life. Such changes have a crucial influence on folliculogenesis. Ischemia-reperfusion injury after ovarian tissue transplantation also leads to changes in the ECM, such as the occurrence of fibrotic areas. However, there is no in-depth characterization of this remodeling yet or any study on how this change could affect the preantral follicle population, notably primordial follicle activation.

Study design, size, duration: Frozen-thawed human ovarian tissue was collected from reproductive- age women (N = 6). In each case, ovarian tissue was divided into 4 fragments: one for non-grafted controls (D0) and three for grafting to immunodeficient mice for 3, 7 and 21 days (D3, D7 and D21, respectively). After grafting, ovarian ECM components were investigated and compared.

Participants/materials, setting, methods: To assess the impact of ovarian tissue transplantation on ECM remodeling, collagen, elastin, fibrilin-1, EMILIN1, and glycosamoniglycans (GAGs) were investigated at different time points (D0, D3, D7, and D21). Both global (ECM from the entire ovarian tissue fragment) and perifollicular (ECM immediately surrounding preantral follicles) ECM were examined by histological staining and immunofluorescence. Computer-assisted quantification of histological staining and immunolabeling was carried out.

Main results and the role of chance: Collagen content from global ECM significantly decreased from D0 to D7 ($p < 0.05$) and D21 ($p < 0.01$). However, no difference was found in the perifollicular collagen concentration. Compared to D0, in the global ECM, thin collagen fibers decreased significantly on D3 ($p < 0.05$). On the other hand, thick collagen fibers tended to increase from D0 to D3. In the perifollicular area of primordial follicles, thin collagen fibers decreased significantly from D0 to D7 ($p < 0.01$) and D21 ($p < 0.05$), while thick fibers slightly increased from D0 to D3 and decreased significantly up to D21 ($p < 0.01$). In the global ECM, GAGs' content did not change significantly after transplantantion. However, they significantly increased around primordial and primary follicles from D0 to D3 and D7 ($p < 0.001$) and decreased from D7 to D21 ($p < 0.001$). While elastin content did not change after transplantation in the whole tissue, it increased significantly surrounding primary follicles on D3 ($p < 0.05$) and then diminished around primordial and primary follicles from D3 to D7 and D21 ($p < 0.001$). Fibrilin-1 concentration significantly decreased at D21 ($p < 0.05$) in the whole tissue and surrounding primordial and primary follicles. EMILIN1 increased significantly at D3 ($p < 0.01$) and D7 ($p < 0.001$) and decreased significantly from D7 ($p < 0.001$) and D21 ($p < 0.01$) around preantral follicles.

Limitations, reasons for caution: While there is an evident remodeling of the ECM, including the one immediately around primordial and primary follicles, due to the cryopreservation and/or transplantation procedure, we cannot ascertain if it could influence folliculogenesis. For this, the assessment of follicle activation parameters (e.g., mTOR, FOXO-1, YAP) is ongoing.

Wider implications of the findings: At the best of our knowledge this is the first study to describe ovarian ECM remodeling after ovarian tissue transplantation. These data may open new insights for a better understanding of the phenomena occurring in the ovarian follicle microenvironment and develop new strategies to prevent primordial follicle loss after transplantation.

O-274 Influence of breast cancer prognostic factors on ovarian reserve and response to ovarian stimulation in fertility preservation

M. Grynberg[1], F. Zeghari[1], E. Sais[1], A. Benoit[1], S. Rakrouki[2], M. Peigne[2], C. Sonigo[3]

[1]*Hôpital Antoine Béclère, Reproductive Medicine & Fertility Preservation, Clamart, France*
[2]*Hôpital Jean Verdier, Reproductive Medicine & Fertility Preservation, Bondy, France*
[3]*Hôpital Antoine Béclère., Reproductive Medicine & Fertility Preservation, Clamart, France*

Study question: Do breast cancer (BC) prognostic factors influence ovarian reserve and response to controlled ovarian hyperstimulation (COH) in the context of fertility preservation (FP)?

Summary answer: BC prognostic factors do not influence ovarian reserve and response to COH in the context of FP.

What is known already: Tumor Grade, triple-negative status, overexpression of HER2, as well as high Ki67 expression are all established prognostic factors for BC, influencing patients' therapeutic management. Yet, there are still concerns about the potential impact of cancer status on ovarian reserve and response to COH. Previous studies analyzing the results of COH in BC patients have shown conflicting findings. However, there is limited data on the potential impact of BC status and prognostic factors on ovarian reserve and response to ovarian stimulation in women undergoing urgent FP.

Study design, size, duration: Observational, bicentric retrospective study including all BC patients who had vitrified oocytes after COH using a random start GnRH antagonist protocol after measurement of serum AMH levels and antral follicle count (AFC) between November 2013 and August 2021.

Participants/materials, setting, methods: Three-hundred-fifty-two BC patients having undergone one cycle of COH were analyzed. Number of oocytes recovered, maturation rate (number of mature oocytes/number of oocytes recovered), and Oocyte Retrieval Rate (number of retrieved oocytes/AFC) were studied according to the patients' general characteristics, ovarian reserve markers, as well as BC diagnostic and prognostic factors: histological type, uni/multifocal character, TNM or UICC stage, hormonal receptors expression, HER2 status, Ki67, Grade, presence of vascular emboli, lymph node and *BRCA1/2* status.

Main results and the role of chance: Overall, mean patients' age was 33.6 ± 4 years. Mean AFC and serum AMH level were 20.5 ± 13.0 follicles and 2.7 ± 4.6 ng/mL, respectively. After ovarian stimulation, 12.5 ± 8.5 oocytes were recovered and 9.3 ± 6.9 were mature and further vitrified. Mean oocyte maturation rate was 74 ± 23%. As expected, patient's age was significantly related to the number of mature oocytes recovered. Indeed, the risk of yielding less than 8 oocytes increased significantly after the age of 35 years. In addition, the oocyte maturation rate was also significantly higher before the age of 30 years, with an OR of 0.64 (0.43-0.96) to obtain a maturation rate <60%. Follicular responsiveness to FSH assessed by the follicular output rate (FORT index) as well as OOR were 30 ± 24% and 61 ± 27%, respectively, and both indexes were not influenced by tumor characteristics. However, maturation rate <60% was significantly related to SBR grade (OR = 0.73 (0.54-0.97), $p<0.03$) and the presence of a *BRCA1/2*-mutation (OR = 0.64 (0.42-0.99), $p<0.03$).

Limitations, reasons for caution: The main weakness is the retrospective nature of the study. Furthermore, the lack of data on reutilization of oocytes

after FP prevents drawing reliable conclusions on the fate of these frozen gametes.

Wider implications of the findings: Our findings indicate that BC prognostic factors do not influence ovarian reserve markers nor the response to ovarian stimulation in the context of FP. Therefore, tumor grade, triple-negative status, overexpression of HER2, and high Ki67 should not modify the FP strategy when COH for oocyte vitrification is considered.

Trial registration number: N/A

O-275 Becoming parents after hematopoietic stem cells transplantation: obstetrics outcomes of spontaneous pregnancies

C. Massarotti[1], S. Chiodi[2], S. Spinelli[2], S. Stigliani[3], E. Angelucci[2], P. Anserini[3]

[1]University of Genova, Academic Unit of Obstetrics and Gynecology, Genova, Italy
[2]IRCCS Ospedale Policlinico San Martino, UO Hematology and Cell Therapy, Genova, Italy
[3]IRCCS Ospedale Policlinico San Martino, Physiopathology of Human Reproduction Unit, Genova, Italy

Study question: Are spontaneous pregnancies after hematopoietic stem cells transplantation (HSCT) of one of the two partners burdened with an increased risk of obstetric complications?

Summary answer: We found a higher risk of Intrauterine growth restriction (IUGR) and preterm delivery after both maternal and paternal HSCT and of pre-eclampsia after maternal HSCT.

What is known already: Conditioning therapies for HSCT are highly gonadotoxic and result in permanent amenorrhea or azoospermia in 70% of patients. Small cohorts of pregnancies after HSCT show an increased risk of complications such as dysfunctional placentation, IUGR or preterm birth. With no more than 9% of survivors reporting a spontaneous pregnancy and the others using of cryopreserved material or gametes donation, it is difficult to untangle the effect of assisted reproduction techniques, gametes donation, radiation on the uterus, and HSCT itself.

Study design, size, duration: This is a retrospective analysis of all spontaneous pregnancies among patients who underwent HSCT for haematological malignancies in a single national referral centre between 1990 and 2016. Obstetric and neonatal outcomes are reported to be compared to the expected incidence in the general population. All patients signed a general informed consent for the use of their anonymized data for research and we obtained the local ethics committee approval.

Participants/materials, setting, methods: We collected the outcome of 53 pregnancies in 30 women after HSCT and 33 pregnancies from 22 men after HSCT. The malignancies treated with HSCT were leukaemia (15 females and 14 males), severe aplastic anaemia (12 and 10), Hodgkin's lymphoma (2 and 1) and myelofibrosis (1 and 1). The conditioning regimen included total body irradiation (TBI) in 20 women (66.7%) and 8 men (36.4%). All patients we included conceived spontaneously after HSCT.

Main results and the role of chance: We observed 53 pregnancies (52 singletons and 1 monochorionic diamniotic twin pregnancy) in women, 12 ± 5.3 years after HSCT. Nine (16.9%) resulted in an early miscarriage. Of the other 44, 15 (34.1%) were uneventful and resulted in a healthy baby born at term. We observed 10 (22.7%) preterm deliveries: 4 very preterm births (1 at 29 and 3 at 31 weeks; 2 spontaneous 2 iatrogenic for pre-eclampsia); 5 moderate preterm births (32 weeks; 4 spontaneous and 1 iatrogenic for pre-eclampsia); 1 late preterm birth (36 weeks, iatrogenic for pre-eclampsia). The incidence of hypertensive disorders in all pregnancies was high (10, 22.7%). In 9 pregnancies (20.5%) there was evidence of IUGR, one of which resulted in an intrauterine foetal death at 35 weeks of gestation. Half of the patients delivered through caesarean section (20, 45.5%). We also reported 33 pregnancies fathered by 22 men who underwent HSCT 7.3 ± 4.3 years earlier. Two pregnancies (6.1%) ended in an early miscarriage. Sixteen of the other 31 pregnancies (51.6%) were uneventful. In 12 cases (38.7%) there was evidence of IUGR, leading to 5 iatrogenic preterm births (16.1%). No maternal hypertensive disorder of pregnancy was reported.

Limitations, reasons for caution: While this is, as far as we know, the largest cohort of spontaneous pregnancies after HSCT present in the literature, the numerosity is still low and we cannot exclude larger numbers would have produced different results.

Wider implications of the findings: HSCT has consequences on reproduction, behind infertility. Pregnancies after HSCT should be followed in a high-risk setting, collecting data collaboratively. The next research effort should be focused on understanding the specific action of the different conditioning therapies used in females and males, to unveil the biological rationale behind these findings.

O-276 Fertility preservation and sperm quality in adolescent transgender patients prior to hormonal treatment

P. Ralph[1], M. Mahmoud[2], D. Schlager[3], W.G. Lee[1], R. Wafa[1], E. Williamson[1], G. Butler[4], D. Ralph[1], P. Sangster[1]

[1]University College London Hospital, Urology, London, United Kingdom
[2]Chelsea and Westminster Hospital NHS Foundation Trust, Urology, London, United Kingdom
[3]University Hospital Freiburg, Urology, Freiburg, Germany
[4]UCL Great Ormond Street Institute of Child Health, Urology, London, United Kingdom

Study question: This study investigated the take-up, hormonal profile and sperm quality in adolescents undergoing fertility preservation via different methods, prior to medical intervention for gender dysphoria.

Summary answer: Fertility preservation via surgical sperm retrieval (SSR) or masturbation, is possible in this group, however long-term data is required to check gamete health.

What is known already: As increasing numbers of adolescents with gender dysphoria (GD) start gonadotrophin-releasing hormone agonists (GnRHa) to delay puberty to minimise psychological distress. However, the uncertainty of the long-term effects of these medications highlights the importance of undergoing fertility preservation (FP) prior to starting any hormone treatment.

Study design, size, duration: Data for adolescents wanting to FP was prospectively maintained. A total of 122 patients were referred for FP, of which 23 declined (19%).

Participants/materials, setting, methods: Young people were counselled for FP and serum testosterone, FSH, and LH were recorded prior to providing semen samples. Semen samples were classified by concentration; normal >15mil/ml, oligospermia <15mil/ml, poor <1sperm/slide, azoospermia. Insufficient samples, or unwillingness to masturbate, meant SSR was offered in a stepwise manner using electroejaculation (EE), TESE and mTESE.

Main results and the role of chance: Most patients (n = 78, 64% - median age 16.7) were able to produce semen by masturbation, cryopreserving an average of 6.6 straws. Sperm concentration was normal in 44% of samples produced, 36% were oligozoospermic, 9% were poor sperm concentration, and 12% were azoospermic. Mean blood results showed: testosterone 12.32nmol/l, FSH 3.83 IU/L, LH 4.39 IU/L.

21 patients required SSR - median age of 14.9. EE was successful in 4 patients, 9 underwent TESE, and 8 underwent mTESE. 4 mTESE patients were azoospermic. Success rate was 77%, with an average of 5.5 vials stored. Semen parameters in this cohort were poor - however possibly adequate for ICSI. Hormone levels were similar to the masturbation cohort: mean testosterone 11.7nmol/l, FSH 3.4 IU/L, LH 3.5 IU/L.

3 patients used GnRHa pre-SSR. Following a washout period, 1 patient remained azoospermic despite a testosterone of 21 nmol/l. The other 2 patients had sperm found with abnormal morphology and motility.

This is the largest UK cohort of transgender girls referred for FP. The results showed that semen parameters were abnormal in 67% of the masturbation samples produced, and within the SSR group, all patient's testosterone levels were >8nmol/l, with an average of 5.5 vials saved.

Limitations, reasons for caution: The quantity of long-term data on whether adolescents end up using their gametes post FP is a factor to

consider with this study, as more evidence is needed in order to display the actual long-term usage of gamete cryopreservation.

Wider implications of the findings: Masturbation is often possible in this group, but alternatively, SSR provides patients with a safe opportunity to potentially have their own biological children in the future.

Trial registration number: not applicable

Study question: Is it safe to have a pregnancy in women with prior history of hormone receptor-positive early breast cancer?

Summary answer: Pregnancy following breast cancer treatments in young women with history of hormone receptor-positive disease is safe with no detrimental effect on patients' prognosis.

What is known already: Breast cancer is the most common malignancy diagnosed in women of reproductive age. Both physicians and patients continue to have concerns about a potential detrimental effect of pregnancy after breast cancer, particularly in the setting of hormone receptor-positive disease. In recent years, several studies have demonstrated the safety of pregnancy after anticancer treatments in breast cancer survivors.

Study design, size, duration: A systematic literature search of Medline, Embase and Cochrane library with no language or date restriction up to January 1st, 2023, was performed following the PRISMA guidelines. We included retrospective or prospective case-control and cohort studies as well as prospective clinical trials comparing survival outcomes of premenopausal female patients with reported pregnancy or not after diagnosis and treatment for hormone receptor-positive breast cancer.

Participants/materials, setting, methods: Included patients were childbearing potential age women with a prior history of hormone receptor-positive early breast cancer. Outcomes of interest were disease-free survival and overall survival. Hazard ratios (HR) with 95% confidence intervals (CI) were extracted. Higgins I^2 index was used to evaluate the degree of inconsistency in the results of the included studies. Pooled HRs were considered statistically significant with a P value of < 0.05 (two-sided).

Main results and the role of chance: Eight studies were eligible to be included in the final analysis. A total of 3,805 patients with hormone receptor-positive breast cancer were included in these studies, of whom 1,285 had a pregnancy after treatments. Median follow-up of the included studies ranged from 3.81 years to 15.8 years.

In three studies (n = 987 patients) reporting on disease-free survival outcomes, no difference was observed between patients with or without a subsequent pregnancy (HR 0.96, 95% CI 0.75 – 1.24, p = 0.781). Six studies (n = 3,504 patients) reported outcomes in terms of overall survival: patients with a pregnancy after breast cancer had better overall survival compared with those without a pregnancy (HR 0.46, 95% CI 0.27 – 0.77, $p < 0.05$).

At the subgroup analysis on timing of pregnancy, no detrimental effect of pregnancy after breast cancer in terms of disease-free survival was observed for patients achieving a late pregnancy (defined as 2 or 5 years after diagnosis) as compared to patients without a subsequent pregnancy (HR 1.08, 95% CI 0.80 – 1.46, p = 0.611). Increased disease-free survival was observed in patients with an early pregnancy (HR 0.63, 95% CI 0.47 – 0.85, $p < 0.05$).

Limitations, reasons for caution: This meta-analysis is based on abstracted data and most of the studies are retrospective cohort studies. Median follow-up in a large proportion of the studies was shorter than 10 years. Adjuvant hormone therapy before and after pregnancy was not available in many studies included.

Wider implications of the findings: Our results strengthen the evidence that having a pregnancy in women with prior history of hormone receptor-positive breast cancer is safe.

Trial registration number: not applicable

Abstract citation ID: dead093.332

O-278 Medical and ethical perspectives of performing ovarian stimulation and oocyte cryopreservation for fertility preservation (FP) in adolescents: 5 years' experience from a tertiary centre

S. Latif[1], K. Sherlock[1], N. Balachandren[1], Y. Atik[1], M. Davies[1], D. Mavrelos[1], S. Lavery[1], E. Yasmin[1]

[1]University College London Hospital, Reproductive Medicine Unit, London, United Kingdom

Study question: What are the medical and ethical challenges of performing ovarian stimulation and oocyte cryopreservation in adolescents and what are the barriers to provision?

Summary answer: Oocyte cryopreservation for benign and malignant indications in adolescents is associated with unique medical and ethical challenges.

What is known already: An improvement in childhood cancer survival, increased transgender care and benign conditions such as haemoglobinopathies requiring stem cell transplant have led to higher representation of adolescent birth-registered females in FP clinics.

FP in adolescents has increased complexities, both physical (pubertal stage, diagnosis) and psychological (accepting diagnosis, processing information, decision-making). Concerns relate to reliability of AMH in adolescents, anticipated response to ovarian stimulation and oocyte quality. Counselling and consenting young people and their families about fertility decisions, often alongside receiving a life-changing diagnosis, is an ethically complex area. Assessing capacity to consent is not straightforward. We report our clinical experience.

Study design, size, duration: This was a retrospective, observational cohort study of 26 adolescent birth-registered females aged 13 to 18 years who underwent ovarian stimulation and oocyte cryopreservation in a specialist unit for fertility preservation between 2018 and 2022. The primary outcome was oocyte yield, secondary outcomes included complications and drop-out rate.

Participants/materials, setting, methods: We included post-pubertal adolescent birth-registered females aged 13 to 18 years who were referred for fertility preservation for high risk of gonadotoxicity from treatment and who commenced ovarian stimulation for oocyte cryopreservation. Data was retrieved from a prospectively managed database. We noted demographic data, ovarian reserve, method of monitoring, response to ovarian stimulation and oocyte cryopreservation and route of egg collection. Documentation on counselling conversations and psychological maturity was retrieved from clinical records.

Main results and the role of chance: There were a total of 29 ovarian stimulation cycles performed in 26 adolescent birth-registered females aged between 13 and 18 years. Indications for fertility preservation included malignancy 62% (16/26), immunological disorders 19% (5/26), gender reassignment treatment 8% (2/26), recurrent ovarian cyst surgery 8% (2/26) and benign haematological disease 4% (1/26). The youngest was aged 13 years and 10 months at the time of egg collection. Minimum time from menarche to ovarian stimulation was 11 months. 23% (6/26) adolescents had previously received chemotherapy. AMH was 2.8-37 pmol/L and AFC 2-36. AFC correlated well with AMH in the majority. Random-start was performed in 54% (14/26) and dual stimulation in 12% (3/26). Number of cryopreserved oocytes was 3-45 and number of MII oocytes cryopreserved 3-35. Ultrasound monitoring was performed transabdominally in 88% (23/26) and transvaginally in 12% (3/26). Egg collection was performed transvaginally in all cases in this cohort, comprising adolescents from varying ethnicities. All cycles proceeded to completion. There were no complications in any cycle, including the 42% (11/26) performed for haematological malignancy. All adolescents were counselled in association with a family member to obtain informed consent. All were assessed as able to comprehend discussions.

Limitations, reasons for caution: There is limited data on performing oocyte cryopreservation in adolescents. Further studies expanding on our findings are needed to support clinicians to perform oocyte cryopreservation in this population. Concerns remain regarding increased aneuploidy rates in this age group compared to women in their 20s. Livebirth outcome data is needed.

Wider implications of the findings: This is the largest case series to date. Post-pubertal adolescents as young as age 13 can undergo ovarian stimulation and oocyte cryopreservation. Transvaginal egg collection is an accepted procedure when counselled appropriately. Clinician experience, correct setting and funding enable a permissive environment for oocyte cryopreservation in this population.

[2]*Instituto Bernabeu, Reproductive Biology, Alicante, Spain*
[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Can certain genetic variants in women cause a genetic predisposition to aneuploidy?

Summary answer: Our results suggest that the maternal variants identified in genes regulating meiotic processes could be useful genetic biomarkers for predicting a predisposition to embryonic aneuploidies.

What is known already: Errors in chromosome segregation during meiosis as chromosome synapsis, crossing-over and spindle building, occur frequently in human oocytes and cause aneuploidy in embryos. These errors increase dramatically in the oocytes of older women. However, the rate of producing aneuploidy oocytes varies among IVF patients for a given age. Recent publications have identified genetic variants that are crucial for producing healthy oocytes in female IVF patients. The association between maternal genetic variants and embryonic aneuploidy risk suggests the potential of using genomic data to predict embryonic aneuploidy risk. Our aim was to identify novel variants and candidate genes for embryonic aneuploidy.

Study design, size, duration: A prospective observational cohort study was done including 127 trophoectoderm biopsies from 29 couples who performed whole-exome sequencing (WES) and PGT-A between November 2019 and March 2022. Women were 35 years old or younger and normal karyotype for men and women. Patients were divided in two groups according to the embryo aneuploidy rate expected by their maternal age: $\leq$ 50% of aneuploid blastocysts as control group(n = 14), and $\geq$ 50% of aneuploid blastocysts as study group(n = 15).

Participants/materials, setting, methods: WES was performed using Trusight One Expanded Sequencing Panel (Illumina®). The following criteria were used for filtering and annotation of candidate variants: (1) minor allele frequency (MAF) <0.05 in the gnomAD and 1000 genomes, (2) variants in genes previously associated with chromosome segregation, chromatin cohesion, meiosis and cell division processes, (3) exonic/splicing boundaries variants, (4) variants having potentially strong/moderate functional effects on the protein evaluated using three in silico prediction algorithms (SIFT, PolyPhen-2 and MutationTaster).

Main results and the role of chance: Overall, the mean female and male age was 26.21 + 4.11y and 40.69 + 9.07y respectively. No differences were shown between groups for patient characteristics. Regarding PGT-A cycle no differences were seen between the number of oocytes and MII retrieved. However, the mean number of biopsied embryos per patient (5.36 + 2.50 vs 3.47 + 1.36; $p < 0.05$) as well as the percentage of embryos biopsied on day 5 (85.33 vs 32.69; $p < 0.05$) were higher in the control group. Finally, as expected, the percentage of aneuploidies was higher in the study group (18.64 vs 71.89; $p < 0.05$). 45 variants were identified in genes potentially associated to the mechanism related to the phenotype. After the variant filtering six probably pathogenic variants were identified. The variants found in the genes were: c.1397T>C (*TLE6*), c.169G>A (*IKBKG*), c.1227A>C (*BUB1B*), c.277G>A (*TP73*), c.190C>T (*PLXNA3*) and c.744C>G (*AURKC*). All variants were heterozygous and all of them were of maternal origin. The females carrying the candidate variants belonged to the study group, and two variants in different genes were identified in one patient. No potentially pathogenic variants were detected in patients from the control group. Therefore, the average detection rate of genetic variants with potential impact in embryo aneuploidy was 33.33% (5/15).

Limitations, reasons for caution: A notable strength of our study is the inclusion of both (male and female) genomic data. On the other hand, our study has certain limitations including the inherent challenges of any observational study, also, the pathogenicity of the identified variants should be validated in further functional studies.

Wider implications of the findings: We described new candidate genes that have never been associated to meiotic embryo aneuploidy and are involved in important biological processes (cell division and chromosome segregation). WES may be considered as an efficient tool to identify patients with higher risk of embryo aneuploidy allowing an individualized genetic counselling in advance.

Trial registration number: Not applicable

P-715 NGS-based metagenome analysis of endometrial microbiome in women with implantation failure after in vitro fertilization: results of a prospective cohort study

S. Hadjidekova[1], D. Parvanov[2], T. Tihomirova[3], S. Chapanova[3], R. Staneva[1], B. Rukova[1], M. Pancheva[4], M. Serafimova[4], R. Ganeva[2], M. Ruseva[2], M. Handzhiyska[2], N. Vidolova[2], D. Metodiev[5], G. Stamenov[3]

[1]*Medical University of Sofia, Medical Genetics, Sofia, Bulgaria*
[2]*Nadezhda Women's Health Hospital, Research and Development, Sofia, Bulgaria*
[3]*Nadezhda Women's Health Hospital, Obstetrics and Gynaecology, Sofia, Bulgaria*
[4]*Nadezhda Women's Health Hospital, Genetics, Sofia, Bulgaria*
[5]*Nadezhda Women's Health Hospital, Pathology, Sofia, Bulgaria*

Study question: We aimed to compare the endometrial microbiome between pregnant and non-pregnant women after frozen embryo transfer (FET) with euploid embryos.

Summary answer: Specific bacteria taxa had significantly higher relative abundance in the endometrium of patients with implantation failure after FET with euploid embryos.

What is known already: Several studies revealed a significant association between the endometrial microbiome composition, including the abundance of Lactobacilli and pathogen species and the occurrence of implantation failure or miscarriage. However, there is still scarce information about the influence of relative abundance of certain bacteria taxa on the pregnancy outcome in patients with idiopathic infertility and FET.

Study design, size, duration: In this prospective observational cohort study endometrial biopsies were collected from 30 women aged between 34 and 45 during the mid-luteal phase (LH + 7) in a natural cycle. FET was performed with euploid embryos (after preimplantation genetic testing for aneuploidy (PGT-A)), up to 6 months after the biopsy. The exclusion criteria for the patients were history of recent inflammatory disease, chronic endometritis, recent antibiotic treatment, moderate or severe endometriosis, adenomyosis, uterine hyperplasia, and endometrial polyps.

Participants/materials, setting, methods: Endometrial microbiota composition was analyzed using 16S rRNA (v4-v5 region) next generation sequencing (NGS). The sequencing data was assigned to bacterial taxonomy and the background-contaminated bacteria were excluded from the analysis. The Student t-test or Mann-Whitney U test for the relative abundance of each bacteria taxa were applied according to normal or not normal distribution of data. A Bonferroni correction was applied to the significant levels obtained.

Main results and the role of chance: The performed analysis of 30 patients with different clinical outcomes, including no pregnancy (n = 16), clinical pregnancy confirmed by ultrasound (n = 14) revealed differences in the endometrial microbiome composition.

Baseline characteristics including age, BMI and duration of infertility were comparable between the studied groups of patients.

In total, 271 distinct bacterial species and 668 bacterial genera were identified. The number of unique species, found in non-pregnant women was 62 (22.88%), while in pregnant patients it was 39 (14.39%). Among them, bacteria with high frequency of occurrence such as *Cutibacterium granulosum, Isoptericola, Acetomicrobium, Marivivens*, *Syntrophomonas and Bacteroides* were found only in patients with unsuccessful implantation while *Bosea* was present only in women with successful implantation.

Based on the analysis of bacteria relative abundance, *Lactobacillus* was the most prevalent genus in both groups. The abundance of this genus was not significantly different between the studied groups. In contrast, *Serratia marcescens, Delftia, Massilia, Glutamicibacter, Lactococcus and Staphyloccocus* were significantly enriched in the non-pregnant group ($p < 0.05$).

Limitations, reasons for caution: Our study is a single-center study with a relatively small sample size.

Wider implications of the findings: The microbiome showed specific composition in pregnant compared to non-pregnant women. It could be hypothesized that an appropriate treatment for optimization of endometrial microbiome content in women with diagnosed microbiome dysbiosis could be beneficial for improvement of pregnancy rates.

Trial registration number: The current research was funded by National Science Fund, Ministry of Education, Bulgaria, Contract № KP-06-N53/14/16.11.2021.

P-720 Biallelic variants in IQCN cause sperm flagella assembly defects and male infertility

J. Dai[1], L. Qi[2], G. Fei[1], L. Guangxiu[3], L. Ge[1]

[1]*Central South University, School of Basic Medical Science, Changsha, China*
[2]*Central South University, Xiangya Hospital, Changsha, China*
[3]*Reproductive and Genetic Hospital of CITIC-XIANGYA, Reproductive Center, Changsha, China*

Study question: What is the effect of defects in the manchette protein IQ motif-containing N (*IQCN*) on sperm flagellar assembly?

Summary answer: Deficiency in IQCN is responsible for sperm flagella assembly defects and abnormal computer-assisted sperm analysis (CASA) parameters, which result in male infertility.

What is known already: Manchette is a transient structure that is involved in the shaping of the spermatid nucleus and protein transport of flagella. Most recently, our group reported that the manchette protein IQCN is essential for fertilization. Variants in *IQCN* led to total fertilization failure (TFF) and defective acrosome structure phenotypes. However, the related function of IQCN in sperm flagella assembly is still unknown.

Study design, size, duration: Fifty infertile males were recruited from the Reproductive and Genetic Hospital of China International Trust Investment Corporation (CITIC)-Xiangya from January 2014 to October 2022.

Participants/materials, setting, methods: Genomic DNA was extracted from the peripheral blood samples of the affected individuals for whole-exome sequencing. The ultrastructure of the flagella was detected by transmission electron microscopy (TEM). CASA was used to test the parameters of sperm motility. An *Iqcn* knockout (*Iqcn*$^{-/-}$) mouse model was generated by CRISPER-Cas9 technology. Immunoprecipitation (IP) followed by liquid chromatography–mass spectrometry was used to select the differentially expressed IQCN-binding proteins. Immunofluorescence was used to validate the localization of IQCN-binding proteins.

Main results and the role of chance: Biallelic variants in *IQCN* (c.3913A>T and c.3040A>G; c.2453_2454del) were identified in our infertile cohort. The sperm from the affected individuals showed irregular "9 + 2" structure of sperm flagella, which resulted in abnormal CASA parameters. Similar phenotypes were observed in *Iqcn*$^{-/-}$ male mice. The CASA parameters in the sperm of *Iqcn*$^{-/-}$ male mice were significantly lower than those in *Iqcn*$^{+/+}$ male mice. The partial of peripheral doublet microtubules (DMTs) and outer dense fibers (ODFs) were absent, or the chaotic arrangement of DMTs were observed in the principal piece and end piece of sperm flagella. The hyperactivation ability of sperm from *Iqcn*$^{-/-}$ male mice was decreased than sperm from *Iqcn*$^{+/+}$ male mice. The CDC42 and IFT protein families are hub proteins that interact with IQCN and regulate flagella assembly during spermiogenesis. Deficiency in IQCN causes the loss of binding with CDC42 and IFT74, which leads to the absence or abnormal localization of CDC42 and IFT74 in mouse and human spermatozoa.

Limitations, reasons for caution: More cases are needed to demonstrate the relationship between the *IQCN* variations and the phenotypes.

Wider implications of the findings: Our findings expand the genetic and phenotypic spectrum of *IQCN* variants in causing male infertility, thus providing a genetic marker for sperm motility deficiency and male infertility.

P-742 Universal genome-wide haplotyping-based preimplantation genetic testing: a systematic seven-year experience at a single center

O. Tšuiko[1], C. Melotte[2], K. Peeraer[3], A. Vanhie[3], E. Denayer[4], J. Vermeesch[5], E. Dimitriadou[4], S. Debrock[3]

[1]*UZ Leuven, Center for Human Genetics, Leuven, Belgium*
[2]*UZ Leuven, Center of Human Genetics, Leuven, Belgium*
[3]*UZ Leuven, Leuven University Fertility Center, Leuven, Belgium*
[4]*UZ Leuven, Centre for Human Genetics, Leuven, Belgium*
[5]*KU Leuven, Department of Human Genetics, Leuven, Belgium*

Study question: To record the outcome and clinical benefit of universal genome-wide haplotyping-based preimplantation genetic testing (PGT).

Summary answer: Universal PGT allows for standardization of protocols and reduces turnaround time. Apart from accurate genetic diagnosis, it also provides chromosome information, improving embryo selection strategies.

What is known already: Developments in genome-wide technologies leveraged the implementation of universal PGT that combines haplotyping and copy number typing across the whole genome. Universal PGT provides diagnosis for any familial monogenic disorder (PGT-M) or structural rearrangement (PGT-SR), and allows for concurrent aneuploidy screening (PGT-A) in PGT-M/SR cycles, all using the same generic protocol and the same biopsy. For this reason, various universal PGT approaches have been developed in the last 2-3 years and are increasingly making their way to the clinic worldwide.

Study design, size, duration: Universal PGT as a first-tier test was implemented at UZ Leuven mid-2014, using in-house developed algorithm (siCHILD/haplarithmisis). This is a retrospective analysis of universal PGT data, collected between 1 January 2015 and 31 December 2022. Data on PGT indication, PGT cycles and biopsy results was extracted. Implantation rate (IR; with IU/EU fetal sac) per embryo transfer was calculated from frozen embryo transfer (FET) cycles for patients with known result by the end of 2021.

Participants/materials, setting, methods: By the end of 2022, 718 couples have successfully finalized preclinical PGT workup. At the time of writing, 573 couples (80%) have further proceeded with PGT cycles. In total, 1264 PGT cycles were performed with day-3 (D3) cleavage-stage (n = 3344) or trophectoderm (TE) biopsies (n = 1524). For 403 patients with known outcome from 954 FET cycles, IR per embryo transfer was calculated per biopsy type and embryo ranking, considering genome-wide chromosome information.

Main results and the role of chance: Couples were referred to PGT due to various autosomal dominant (AD, 65%), autosomal recessive (AR, 14%) and X-linked disorders (XL, 10%). Various PGT-M indications encompassed >200 genes in total, but almost 20% of couples enrolled due to inherited BRCA1/BRCA2 mutations. PGT-SR was indication in 7% of cases, mainly for familial microduplications/deletions (64%). For all PGT cycles, approximately 15% and 18% of all performed D3 and TE biopsies, respectively, were scored as abnormal largely due to meiotic errors in the embryo. All unaffected embryos were further ranked as R1 (euploid) or R2 (mosaic), and the number of R2 embryos was expectedly higher after D3 biopsies, compared to TE biopsies (250/1063, 23.6% vs 37/510, 7.3%, $p<0.001$). In accordance with inheritance mode, the number of unaffected embryos suitable for transfer was significantly lower in AD PGT cycles, compared to AR (32.3% (1116/3455) vs 44.0% (262/596) ; $p<0.0001$)). For 403 patients with FET cycles, IR was higher in R1 vs R2 embryos after D3 biopsy (231/590, 39.2% vs 30/159, 18.9 %, $p <0.0001$), whereas no difference was observed between R1 and R2 embryos after TE biopsy, although low number of R2 embryos after TE biopsy was transferred (85/142, 59.9% vs 7/12, 58.3%, *p=ns).*

Limitations, reasons for caution: The analyzed data is derived from a single center and the clinical outcome may not reflect the experience of other IVF/PGT centers due to confounding factors, such as PGT indication, used PGT technology and IVF lab practice.

Wider implications of the findings: The current dataset provides a comprehensive overview on general trends and outcome of universal PGT practice. Apart from accurate genetic diagnosis, universal PGT provides information on chromosomes, which improves embryo selection for transfer. This in turn impacts clinical counselling, interpretation and reporting of the results, and embryo transfer policies.

Trial registration number: Not applicable

Abstract citation ID: dead093.337

P-727 New methods reveal the true incidence of DNA contamination in PGT-A samples for the first time and avoid errors that could result in serious misdiagnoses

G. Clark[1,2], D. Babariya[1], A. Del Canto Cano[1], E. Fernández Marcos[3], L. Parnell[4], M. Kilbee[1], V. Ceban[1], B. Infantes[1], C. Coudereau[1], K. Spath[1], D. Wells[1,2]

[1]*Juno Genetics, Clinical Genetics, Oxford, United Kingdom*
[2]*University of Oxford, Nuffield Department of Women's and Reproductive Health, Oxford, United Kingdom*
[3]*Juno Genetics, Clinical Genetics, Valencia, Spain*
[4]*University of Manchester, Maternal and fetal health research centre, Manchester, United Kingdom*

Study question: What is the occurrence of contamination in embryo biopsy samples and could this lead to incorrect interpretation of preimplantation genetic testing for aneuploidy (PGT-A) results?

Summary answer: On average, contamination affects 0.4% of biopsy samples, but can be significantly more common in some clinics. Misdiagnosis can occur when contamination is not detected.

What is known already: Until recently, most commercially available platforms for PGT-A have utilised whole genome amplification followed by sequencing of a random selection of DNA fragments scattered across the genome using next generation sequencing (NGS). However, the simple quantitative measurements of DNA fragments derived from each chromosome, provided by such methods, cannot reveal when a biopsy sample is contaminated with non-embryonic DNA. Negative controls are seldom used during PGT-A and are inadequate as they do not evaluate contamination in the actual tube containing the biopsy specimen. The extent to which failure to detect DNA contamination is a problem for PGT-A is unknown.

Study design, size, duration: This was a retrospective study involving analysis of 49,287 trophectoderm biopsy samples that underwent PGT-A over a three-year period. Embryos found to have a contaminated biopsy specimen typically underwent a second biopsy. In such cases, results from the two samples were compared to ascertain whether the contaminated sample would have been misdiagnosed if the analysis had been restricted to examining only the relative chromosome copy number, as is the case for most NGS-based PGT-A methods.

Participants/materials, setting, methods: All trophectoderm biopsies underwent targeted DNA amplification and next generation sequencing using a highly validated PGT-A method that evaluates the relative chromosomal copy number, similar to traditional PGT-A methods, but combines this with analysis of variations in DNA sequence (single nucleotide polymorphisms - SNPs). The genotype of each SNP, and the relative quantity of DNA fragments containing each of the different alleles, allows detection of otherwise invisible states, such as triploidy, haploidy, and contamination.

Main results and the role of chance: From the 49,287 TE biopsies analysed, contamination with non-embryonic DNA was detected in 218 (0.44%). There was variation in the rates of contamination between the 25 clinics that provided samples, ranging between 0% and 1.5%. Additionally, one clinic had a contamination rate of 7.7%, but the number of biopsies derived from that site was considered too small for reliable evaluation (n = 26). 156 of the embryos with a contaminated biopsy specimen underwent secondary biopsy (71.5%), allowing the relative chromosome copy number result from the contaminated specimen to be compared to that obtained from an uncontaminated sample. The results were split into three categories: 1) no change in interpretation between the first (contaminated) and second biopsy specimens; 2) false positive – the contaminated sample was euploid but would have been wrongly interpreted as triploid and would have been erroneously discarded, potentially impacting the patients chances of achieving a pregnancy; 3) false negative – the contaminated sample was fully aneuploid but would have been incorrectly classified mosaic or euploid and could have been eligible for transfer, potentially leading to implantation failure or abnormal pregnancy. 19% of contaminated samples gave a false negative result, while 24% gave a false positive, appearing to be triploid.

Limitations, reasons for caution: It is not possible to determine the origin of contaminants with certainty without having DNA from the contamination source for comparison. Additionally, we were unable to conclude whether contamination is more likely to occur in IVF or ICSI cycles as only 3% of samples were fertilized using IVF.

Wider implications of the findings: Contamination detection during PGT-A is important to prevent misdiagnosis of embryos. Misclassification due to undetected contamination can lead to discard of potentially viable embryos. It can also lead to the transfer aneuploid embryos, wrongly classified as mosaic, which could lead to increased rates of implantation failure, miscarriage and aneuploid pregnancy.

Trial registration number: Not applicable

Abstract citation ID: dead093.338
P-743 Semen samples quality and blastocysts diversity after PGT-A

C. Albanese[1], D. Perruzza[1], S. Azzena[1], A. Crippa[1], S. Graziosi[1], G. Bilotta[1], M.C. Magli[1], L. Gianaroli[1]

[1]*S.I.S.Me.R., Reproductive medicine unit, Bologna, Italy*

Study question: Does semen samples quality contribute to blastocyst diversity by correlating with the presence of DNA in the blastocoelic fluid (BF)?

Summary answer: Semen samples quality is associated with the detection of DNA in BFs from both euploid and aneuploid blastocysts

What is known already: DNA was detected by whole genome amplification (WGA) in BFs from expanded blastocysts dependently on the blastocyst chromosome condition (assessed by PGT-A on trophectoderm (TE) cells), being more frequent in aneuploid blastocysts. TE-euploid blastocysts with positive BF-WGA also seem to have less chances to implant compared to those with failed BF-WGA. The extrusion of abnormal cells from the embryo proper was proposed as a mechanism triggered by the mosaic embryo to eliminate abnormal cells. Severe male factor samples are at risk of causing embryo mosaicism. Possible association between semen quality and DNA in BFs has not yet been investigated.

Study design, size, duration: This retrospective cohort study included 115 patients (maternal age 37.9 ± 4.1), which underwent PGT-A in the last three years. The aim of the study was to evaluate whether the detection of DNA in BFs was correlated with semen samples indices. Both TE-euploid and TE-aneuploid blastocysts were considered for the analysis and stratified according to the semen samples quality as normozoospermic (N), moderate oligoasthenoteratozoospermic (m-OAT) and severe OAT (s-OAT) following the 2021 WHO criteria.

Participants/materials, setting, methods: BF and trophectoderm (TE) biopsies were collected from high grade expanded blastocysts before vitrification, and submitted to WGA. Amplification after WGA was evaluated by loading an aliquot of the amplified product onto a 1.5% agarose gel. 24-chromosome analysis was performed on TE biopsies. To assess the impact of semen samples quality on the detection of DNA in BFs, a multiple logistic regression analysis was performed correcting for maternal age as a confounding factor.

Main results and the role of chance: The BF from 590 blastocysts (265 TE-euploid and 325 TE-aneuploid) were submitted to WGA. In TE-euploid blastocysts, 125 derived from N semen samples, 52 from m-OAT, and 88 from s-OAT. The incidence of positive BF-WGA was proportional to the severity of the male factor condition and occurred in 48.0% of blastocysts originated from N samples, in 55.8% of blastocysts derived from m-OAT, and in 60.2% of blastocysts from s-OAT. In TE-aneuploid blastocysts, 178 originated from N semen samples, 80 from m-OAT, and 67 from s-OAT. The incidence of positive BF-WGA showed an opposite trend compared with the TE-euploid group being detected in 64.0% of blastocysts originated from N samples, in 66.3% of blastocysts derived from m-OAT, and in 52.2% of blastocysts obtained from s-OAT. The relationship between semen quality and positive BF-DNA amplification was confirmed by a multiple logistic regression model setting the BF-WGA as the outcome variable. In the TE-euploid blastocyst cohort, s-OAT showed an odd ratio (OR) of 1.78 (95% CI: 1.02-3.14; p=0.045), whereas in the TE-aneuploid blastocyst group, s-OAT displayed an OR of 0.55 (95% CI: 0.31-0.98; p=0.043).

Limitations, reasons for caution: This is a retrospective cohort study including a limited number of cases where the different categories of sperm samples were not equally represented. Although the results of BF-WGA were evaluated per single blastocyst, they cannot be considered independent variables.

Wider implications of the findings: In s-OAT samples, abnormal cell elimination is especially active in TE-euploid blastocysts, whereas in TE-aneuploid blastocysts the efficiency of this process is reduced suggesting the difficulty of eliminating abnormal cells in an aneuploid background. BF-DNA amplification is a minimally invasive tool contributing additional knowledge to elucidate blastocyst diversity.

O-280 Reading between the lines: Evaluating the clinical benefit of laboratory interventions from published studies

J. Wilkinson[1]

[1]*University of Manchester, Centre for Biostatistics, Manchester, United Kingdom*

Embryologists rely on both randomised and non-randomised studies evaluating the effectiveness and safety of interventions. However, many of these studies contain subtle but critical methodological limitations, which are not identified by peer reviewers. Embryologists must therefore be critical consumers of the published literature. In this talk, I will highlight some common, serious methodological flaws occurring in studies of embryological interventions, and will give intuitive explanations of both the problems and the impact they may have on study results. This includes methods of analysing randomised controlled trials which nullify the benefits conferred by randomisation, and flawed methods of identifying study groups in observational studies which prevent any meaningful evaluation of an intervention's benefit. I will discuss underappreciated methodological challenges in studies evaluating artificial intelligence algorithms for embryo selection, which limit their usefulness, and will outline superior approaches to evaluate these interventions.

O-282 Role of extra-cellular vesicles in reproduction

R. Machtinger[1]

[1]*Sheba Medical Center and Tel-Aviv Univeristy- Israel, Obstetrics and Gynecology, Herzlia, Israel*

Extracellular vesicles (EVs) are bilayer-membrane-bound vesicles isolated from biofluids and tissues. Recently, these organelles have been recognized as a novel mode for inter and intra-cellular communication. The three critical

subtypes of EVs include exosomes, microvesicles, and apoptotic bodies. They can be discriminated according to their size, cargo, biogenesis, release pathways, and functions.

These organelles serve as vehicles for transferring bioactive molecules as lipids, proteins, cytokines, and regulatory molecules as RNAs, locally and remotely. A wide range of cell types releases EVs, and their cargo differs under normal and pathological conditions. These facts make them possible biomarkers for diagnosing and treating different medical conditions.

Isolation of EVs from various female and male reproductive tissues such as prostate, epididymis, seminal fluid, fallopian tube, cumulus, and mural granulosa cells, oocytes, embryos at various developmental stages, endometrium, and decidua has been described.

Oogenesis, sperm maturation, fertilization, embryo development, and implantation are composite processes highly reliant on the interaction between tissues and cells. Existing data show that miRNAs and proteins in epididymal fluid associated with testicular maturation are transferred to the sperm by EVs

Ovarian follicular growth is a synchronized process comprising bidirectional communication between the oocyte, cumulus, and mural granulosa cells. Some studies have identified EVs from several species' follicular fluid (FF), including bovine, equine, and human. To date, data linking EVs with oogenesis are primarily descriptive. EV micro-RNA (EV-miRNA) isolated from FF target pathways as mitogen-activated protein kinase (MAPK), wingless signaling pathway (WNT), epidermal growth factor receptor (ErbB), and transforming growth factor beta (TGFß). These pathways are related to folliculogenesis, meiotic resumption, and ovulation.

EV-miRNAs isolated from follicles that contained mature oocytes were associated with fertilization potential and embryo quality. In addition, EVs derived from microvillous-rich oolemma may neutralize acrosome reaction and prevent polyspermy.

Animal and human studies have confirmed that embryos at various developmental stages secrete EVs into the extracellular medium, and embryos internalize EVs. The number, miRNA profile, and size of EVs secreted vary across the cycle and according to embryos' developmental potential.

Endometrial EVs release miRNAs essential for the blastocyst's adhesion. In ovine, EVs were identified from the uterine lumen and uterine flushing during implantation. Uterine lumen flush EVs were internalized by the trophectoderm cells in the conceptus, reducing trophectoderm cell proliferation.

The study of EVs in reproduction has increased exponentially in the last few years. Evidence support that these organelles contribute to oogenesis, fertilization, embryo development, and implantation. Further research in EVs will help us expand noninvasive methods and identify new biomarkers in the reproductive field.

INVITED SESSION

SESSION 86: WEIGHT-LOSS INTERVENTION PROGRAMS IN SUBFERTILE WOMEN: TOO MUCH FOR TOO LITTLE ?

Wednesday 28 June 2023 Hall D1 12:00 - 13:00

Abstract citation ID: dead093.343
O-283 Impact of metabolic syndrome and effect of treatment on male and female reproductive capacity

R. Legro[1]

[1]*The Pennsylvania State University College of Medicine, Obstetrics and Gynecology, Hershey, U.S.A.*

Obesity is associated with sub fertility and multiple adverse pregnancy outcomes including miscarriage and later pregnancy complications such as pre-eclampsia and gestational diabetes. Weight loss preconception is recommended for women with obesity and infertility. The etiology of infertility may affect the response to weight loss with WHO type 2 patients more likely to ovulate spontaneously or with oral medications after modest weight loss. The evidence for weight loss improving fertility outcomes is weak for women with unexplained infertility. There may also be unrecognized harms to weight loss including increased risks of miscarriage and weight rebounding excessively during pregnancy. Unique hurdles to weight loss interventions including the types, duration and best comparators will be discussed. Blanket recommendations that weight loss improves fertility and pregnancy outcomes should be avoided. Other factors such as age and ovarian reserve should be factored into any preconception weight loss strategies

INVITED SESSION

SESSION 87: WHAT WAS AND WHAT IS NORMAL IN MALE FERTILITY EVALUATION

Wednesday 28 June 2023 Hall D4 12:00 - 13:00

Abstract citation ID: dead093.345
O-285 The 6th edition of the WHO manual for the examination and processing of human semen: How should it affect our practice?

L. Björndahl[1]

[1]*Björndahl- Lars, Andrology Laboratory- ANOVA- Karolinska University Hospital, Stockholm, Sweden*

The WHO laboratory manual (World Health Organization 2021) has widened the scope of semen examination from primarily a prognostic tool for Medically Assisted Reproduction (MAR) by indicating the importance of evaluating men with possible disorders in male reproductive functions. Practical instructions for basic examination have been clarified and focused to measures of sperm production and motility as judged from sperm number, motility (vitality if poor motility) and sperm morphology. In addition to the recommendations by the WHO, an international standard based on the same laboratory science as the WHO manual has been published (International Organization for Standardization 2021) to facilitate for laboratories to provide reliable results of semen examination.

Each ejaculate must be handled with great care before analysis begins. Time and temperature between sample collection and start of assessments is crucial. To reduce assessment variability, it is essential to ascertain that the examined aliquots are representative for the entire ejaculate and that the number of observations is sufficient to reduce the risk for significant influence of random factors. The former is handled both by aliquot volume (at least 50 µL for sperm concentration) and replicate assessment and comparison that the two assessments don't differ too much. Regarding number of observations, 400 sperm counted in sperm concentration and in sperm motility assessments is required to reduce this source of errors to ± 10%. For assessment of sperm morphology and vitality a minimum number of observations is 200 spermatozoa.

To achieve acceptable performance, thorough in-house training is necessary. There are protocols how to set up and run such schemes (Mortimer 1994, 1994). Basic medical laboratory standards also require that the laboratory regularly performs internal quality control to monitor that inter- and intra-personal variability is under control. Each laboratory should also participate in an external scheme for quality assessment (EQA) (International Organization for Standardization 2012).

For the proper interpretation of semen examination results reference limits are important. However, the reference limits suggested by the WHO (World Health Organization 2021) come from a very mixed group of men and should therefore not be mistaken for true limits between fertility and infertility. The new WHO manual therefore argues for development of decision limits (when is it reasonable to act?) that are much more important than limits from a mixed population.

It has been argued that semen examination must be better standardized (Björndahl et al. 2016), but the compliance has been almost non-existent (Vasconcelos et al. 2022) leading to even stronger appeals for stronger improvement of basic laboratory investigations of male reproductive functions (Björndahl et al. 2022)

P-387 Exploring the Potential of Artificial Intelligence in Providing Infertility Consultations and Answers: can it replace the infertility specialist? A hybrid study.

G. Buzzaccarini[1], G. Grecchi[1], G.A. Papa[1], G. Carnemolla[1], N. Salmeri[1], R. Villanacci[1], P. Giardina[1], S. D'Alessandro[1], M. Molgora[1], D. Marzanati[1], L. Pagliardini[1], V.S. Vanni[1], A. Alteri[1], M. Candiani[1], E. Papaleo[1]

[1]IRCCS San Raffaele Scientific Institute, Obstetric and Gynecology Clinic, Milano, Italy

Study question: What are the differences between the accuracy of answers given by an AI-based infertility consultation system compared to those of an infertility specialist?

Summary answer: OpenAI, an AI platform, does not have the potential to provide proper consultation to women searching for answers regarding their infertility.

What is known already: Artificial intelligence (AI) has been recently introduced in the field of human reproduction, both in controlled ovarian stimulation algorithms and laboratory decisions. Additionally, AI-enabled technology has been used to facilitate online communication between patients and healthcare professionals. However, the recent widespread use of AI-based chatbots is causing serious concerns about their use in providing medical advice. Furthermore, the capacity of AI-based chatbots to answer intricate questions about infertility and its treatment has yet to be explored. Despite AI being declared to not be able to provide accurate medical advice, a study assessing this has not yet been conducted.

Study design, size, duration: The aim of this prospective observational study was to assess the ability of OpenAI, an artificial intelligence (AI) platform, to provide appropriate infertility answers to women asking online questions. OpenAI generated answers and answers provided by infertility specialists (control) were both judged by external, blinded infertility specialists in terms of scientific appropriateness (Correctness), detailed feature (Accuracy), ability to properly answer the infertility question (Precision) and providing human kindness (Empathy).

Participants/materials, setting, methods: 20 online infertility questions were retrieved from the web. For each question, the openAI playground was questioned "Answer this question. You are the infertility specialist". The AI platform was available on the internet website https://beta.openai.com. The evaluators were four different infertility specialists with more than 20 years' experience and they were blinded to the purpose of the study and the presence of AI answers. Four criteria were used (1-5): Correctness, Accuracy, Precision and Empathy.

Main results and the role of chance: The mean total score for the human answer without the empathy criteria was 11.18/15 (14.53/20 with empathy). The AI answer provided total score of 8.95/15 and 12.50/20 respectively. At the Mann-Whitney test, both the total scores showed a statistically significant difference ($p < 0.001$). With a tolerance of -/+ 0.5 total score without empathy, the AI answers were evaluated similar for 4/20 answers, compared to the human answers and better than the human infertility specialist answer in 2/20. Of outmost importance, none of the evaluators suspected the presence of an AI engine tool. Intriguingly, evaluating the absolute impact, the scores obtained from AI were higher than we expected and showed great results. This result strongly suggests that, although not able to overcome an infertility consultation, AI has shown great abilities in mimicking an infertility specialist. AI usage in providing infertility answer or consultation should be not considered due to lack of scientific appropriateness, answering details, and question-points precision. However, the results obtained from AI showed borderline performance with the human's even at the evaluation of a team of blinded infertility specialists. Indeed, the AI tool should be appropriately addressed given its worldwide spread.

Limitations, reasons for caution: Further research is needed to understand the limitations and assess the validity of this engine in providing appropriate medical advice. Caution and ethical concerns should be taken into consideration for the coming future.

Wider implications of the findings: OpenAI also contributed to develop this study, by giving answers to our questions on the potential study design. Moreover, and intriguingly, this abstract is the first hybrid-written (human and AI) of the history of ESHRE abstract presentation.

Trial registration number: Not Applicable

Abstract citation ID: dead093.348

P-390 Uterus transplantation, is it ethical to authorize living donor programs when no other alternative to this type of donation is possible?

I. Carton[1], L. Dion[1], B. Hofmann[2], V. Lavoué[1]

[1]university hospital of Rennes, Gynaecology- obstetrics and human reproduction, Rennes, France
[2]University of Oslo, Senter for medical ethics, Oslo, Norway

Study question: Can we guarantee a freely taken decision for a living donor when she represents the only possibility for a loved one to have a uterus-transplantation?

Summary answer: The autonomy and freedom of the donor may be reduced by the awareness that they are the only possibility for the relative to achieve parenthood.

What is known already: The subject is unknown unlike to the many studies that compare surrogacy to uterus transplantation. The closest study is Lisa Guntram's 2021 paper "May I have your uterus? The contribution of considering complexities preceding live uterus transplantation" which looks at the difficulty of simply having to ask this question. She highlights that the answer, including a refusal, can have both short-and long-term consequences.

However, it does not specifically address the constraint that this represents, or rather adds to the already complex problem of not offering any alternative to the living donor. As a reminder, this is a complex and risky surgery

Study design, size, duration: This is a qualitative study based on semi-structured interviews. The study protocol was submitted to an independent ethics committee for approval. The study was carried out during the year 2022. Communication was made through patient associations and participants volunteered to take part in the study.

Participants/materials, setting, methods: We interviewed 9 health professionals involved in uterus transplantation programmes in France and Sweden and 9 women with Rokitansky syndrome. The health professionals were gynaecologists or psychologists. The interviews were recorded, manually transcribed and analyzed using a thematic content analysis method. The analysis of the interviews was carried out in double reading.

Main results and the role of chance: Many centres that offer the possibility for women with Rokitansky syndrome to be transplanted do not offer a deceased donor uterus transplant programme or surrogacy.

According to some of the professionals interviewed, mothers, the main potential donors identified, already feel guilty about their daughters' disease (Rokitansky syndrome). They cannot therefore consider, despite the risks involved, refusing to donate their uterus. But how can an agreement based on guilt be considered? Furthermore if there is no other solution if they refuse to allow their daughter to become both a legal and biological mother.

In the case of uterus transplantation, is the institution that has legalized such a procedure putting them in this difficult position bears some responsibility?

A total ban, however, would remove the hopes of these women.

According to some professionals and women, the constraint is reduced if women know that in the event of the absence of an identified donor in their entourage, the possibility of resorting to a deceased donor is possible.

Thus, freedom is possible at all levels: asking or not for a uterus transplant and having the possibility to accept or not to donate

Limitations, reasons for caution: This study is based on 18 interviews, which is a small number. Furthermore, all the interviews are in Europe, and only in 2 countries, which may make extrapolation to a larger scale difficult. It has the merit of opening the discussion

Wider implications of the findings: Even if it seems difficult to legislate on a global scale, it is necessary to reflect on the prerequisites before endorsing a transplant programme, including the notion of an alternative to be offered to donor/recipient couples by encouraging the development of a deceased-donor programme, altruistic donors, or by legalizing surrogacy.

P-385 Are you completely aware of your citations? A cross-sectional study on improper citations of retracted articles in medically assisted reproduction

S. Minetto[1], D. Pisaturo[2], G.C. Cermisoni[1], E. Rabellotti[1], L. Pagliardini[1], M. Candiani[1], E. Papaleo[1], A. Alteri[1]

[1]IRCCS San Raffaele Scientific Institute- Milan- Italy, Obstetrics and Gynaecology Unit, Milan, Italy
[2]CIONIC- Inc, CIONIC- Inc, San Francisco, U.S.A

Study question: Are authors aware that they have cited a retracted paper in their manuscripts in medically assisted reproduction (MAR)?

Summary answer: Most corresponding authors were unaware of their own inappropriate retracted citations, mainly due to improper notification of retraction status.

What is known already: Retraction is a severe penalty in scientific research for various reasons, ranging from honest mistakes made in good faith to deliberate misbehaviour. Scientific publications with compromised integrity should be retracted and, once retracted, only be cited in the context of that retraction. However, it has long been recognized that large numbers of citations of retracted papers occur, usually without mentioning the retraction. Concern about the study of inappropriate citation of retracted articles has been gaining momentum in recent years. However, this topic has yet to be considered in medically assisted reproduction.

Study design, size, duration: From December 23, 2022 to January 29, 2023, a cross-sectional study based on an online survey was conducted to acquire information on the irregular citation pattern from corresponding authors who cited a retracted article. The survey was set up in Google Forms and included seven questions. The survey was distributed via e-mail to corresponding authors who cited a retracted paper in their study using the Mailchimp platform. Three reminders were sent about ten days apart.

Participants/materials, setting, methods: A dataset of retracted articles in MAR published up to July 2022 was collected from PubMed and Retraction Watch, according to our systematic review (registered with PROSPERO, CRD42020185769). For each retracted article, a complete list of cited articles published was retrieved from PubMed and Google Scholar. Search, and screening were performed independently by two authors, and any disagreement about the eligibility of a study was resolved through discussion with a third author.

Main results and the role of chance: Forty-three MAR retracted articles were selected, of which 36 were included. Specifically, manuscripts that cited a retracted article in the year of publication of the retraction notice or the following year were excluded from this analysis ($n = 7$) to reduce instances of citation by authors potentially unaware of the retraction of the cited article. The survey was sent to 267 corresponding authors and 39 filled out the survey (participation rate 14.6%). Most respondents (79.5%) were unaware of the retraction status of the cited articles, mainly due to inadequate notification of retraction status in the research database (33.3%), inadequate notification of retraction status in the journal (24.2%), or use of stored copies of the retracted manuscript (15.2%). Regarding bibliography building, 48.7% of respondents declared that they use both online databases and previously printed copies to search scientific manuscripts. Notably, the majority of authors (61.5%) declared that references were entered and checked by only one author before submission and that, during the review process, no one received concerns from editors and/or reviewers about the retracted references. Finally, according to 53.8% of participants, no check of retraction notices is performed, while only 12.8% check both the journal website and scientific databases.

Limitations, reasons for caution: This online survey on citation inappropriateness provided some insight into the justifications correlated with it. Despite the approach used to identify retracted articles in the context of MAR and citations, some may have been missed. In addition, incorrect or disused e-mail addresses constituted a limitation for this study.

Wider implications of the findings: Correcting publications containing references that are subsequently retracted is significant for systematic reviews, meta-analyses, and guidelines. Citations of retracted articles perpetuate

erroneous scientific data, even though assessing the accuracy of citations requires considerable effort. Proper notification of retraction status and cross-checking of citations can help prevent errors.

P-388 Is access to egg freezing equitable and fair? A comparison between policies in Belgium and France

H. Mertes[1], M. De Proost[2]

[1]*Ghent University, Department of Philosophy and Moral Sciences, Gent, Belgium*
[2]*Ghent University, Department of Philosophy and Moral Science, Ghent, Belgium*

Study question: What underlying norms and values are the inclusion and exclusion criteria for egg freezing in Belgium and France based on? Are they equitable and fair?

Summary answer: Exclusion criteria are desirable from a distributive justice viewpoint. While age limits are justifiable, criteria such as oncological vs non-oncological and gender are not equitable.

What is known already: In 2018, the Belgian federal institute for health insurance (RIZIV or ENAMI) decided on health insurance coverage for the retrieval, freezing and storing of gametes and gonadal tissues for fertility preservation. This coverage is however not available to all candidates for egg freezing, but strongly directed towards oncology patients. France took a different approach. Since the French Law on Bioethics was passed in August 2021, egg freezing is available to all women between their 29th and 37th birthday. Egg harvesting is covered by public health insurance, but not the storage costs.

Study design, size, duration: This is a normative analysis in which the different inclusion and exclusion criteria from the Belgian and French system are critically analysed in light of existing ethical scholarship on access to egg freezing from the past decade. Special attention is paid to arguments relating to justice as fairness.

Participants/materials, setting, methods: Literature research; normative analysis

The method that is used to bring empirical data (as found in literature research) and normative ethics together is the 'Wide Reflective Equilibrium', the most commonly used method in bioethics.

Main results and the role of chance: While the French system, allowing access to a great range of people, appears to be the most fair, the opportunity costs involved plead for the implementation of inclusion and exclusion criteria to make sure that resources are allocated in a more equitable manner. These criteria should be based on effectiveness and social justice. Looking at the currently implemented criteria, the distinction between medical and non-medical or between oncological and non-oncological conditions is difficult to justify given the large grey area where these categories overlap. For example, in Belgium several categories of people at risk of losing their fertility are excluded: transmen receiving gender-confirming therapy, people needing a stem cell transplant for other than hematopoietic reasons (e.g. sickle cell anaemia) or women nearing the end of their reproductive lifespan (also if due to previous cancer treatment). Arguments in favour of age limits are effectiveness and the avoidance of false hope for people of advanced reproductive age. Arguments against are founded on concerns of ageism and social injustice. Of the potential arguments arguing for gender limits – specifically the exclusion of transmen – none appear convincing, while access for transmen is problematic both in Belgium and France.

Limitations, reasons for caution: This analysis is a case study of two countries, not a comprehensive or representative analysis of European policies.

Wider implications of the findings: Countries that are considering implementing systems for coverage of egg freezing by public funding, can learn from these case studies to better finetune their inclusion and exclusion criteria.

Trial registration number: N/A

SELECTED ORAL COMMUNICATIONS
SESSION 89: CLINICAL APPLICATION OF PGT

Wednesday 28 June 2023 Hall A 14:00 - 15:15

Abstract citation ID: dead093.351
O-287 Preimplantation genetic testing for monogenic disease (PGT-M) where results are only based upon analysis of linked polymorphisms/haplotypes risks serious diagnostic errors

A. Haj Ali[1], M. Ampiah[1], H. Abdous[1], D. Babariya[1], A. Raberi[1], D. Wells[1]

[1]*Juno Genetics, Laboratory, Oxford, United Kingdom*

Study question: PGT-M often involves diagnoses based upon the analysis of polymorphisms linked to the mutant gene. Are such methods sufficiently reliable to be used alone?

Summary answer: Several problems can lead to misdiagnosis when linkage analysis is used in isolation. Therefore, PGT-M should also include direct mutation testing (DMT) whenever possible.

What is known already: Many PGT-M strategies involve analysis of DNA sequence polymorphisms in close proximity to the mutant gene, which have specific alleles that are inherited along with the disease. Unlike diagnostics that focus on detection of specific mutations, which can be unique to individual families, PGT-M protocols using linked polymorphisms can usually be reused for multiple families. Indeed, strategies such as karyomapping, which assess thousands of polymorphisms across the genome, provide a single method applicable to numerous diseases. Such methods are attractive since the work-up required for individual cases is minimal, reducing costs and patient waiting times. However, are such methods safe?

Study design, size, duration: Over a period of three years, we carried out 261 PGT-M cases covering 312 different mutations in 116 genes. Each couple requesting PGT-M provided blood samples from which DNA was extracted. The patients underwent IVF and embryos that reached the blastocyst stage were subjected to trophectoderm biopsy. All PGT-M cases involved the use of DMT to interrogate the mutation site(s). The DMT result was supplemented by analysis of multiple informative linked polymorphisms, as described below.

Participants/materials, setting, methods: Embryo biopsy samples were subjected to multiple displacement amplification (MDA). Mutation site(s) were amplified from MDA products using PCR and mutations were revealed using minisequencing, Sanger sequencing, or DNA fragment size analysis. Parental and embryo samples were also analysed using karyomapping, involving the genotyping ~300,000 polymorphisms scattered across the genome with a microarray. Where possible, samples from additional family members were also tested, allowing determination of which alleles of linked polymorphisms accompanied mutant gene copies.

Main results and the role of chance: Multiple PGT-M cases were identified where DMT prevented potentially serious errors. In five cases, diagnostic reports provided to the PGT laboratory were incorrect. These reports are vital for defining the genetic status of an individual, allowing specific alleles of linked polymorphisms to be correctly associated with mutant or normal gene copies. In three cases, DMT carried out on patient samples during the initial work-up revealed that, contrary to the report, the patient did not carry a mutation. Therefore, PGT-M was not indicated, saving patients from the stress and expense of an unnecessary PGT-M cycle and avoiding discard of healthy embryos. In the other two cases, errors in the reports would have inverted all results based upon linkage analysis, leading to transfer of affected embryos and discard of unaffected embryos, potentially causing a serious misdiagnosis. Thirteen more cases had recombination events extremely close to the mutation site, preventing determination of the status of the embryos based on analysis of nearby polymorphisms. Two further cases displayed consanguinity (undisclosed by the patients), leading to large areas of homozygosity in the

genome, precluding use of linked polymorphisms for diagnosis. In all these cases DMT unequivocally confirmed the true status of patients and their embryos.

Limitations, reasons for caution: In ~8% of PGT-M cases at least one embryo could not be accurately diagnosed without DMT, while in ~1% of cases our routine use of DMT averted a serious misdiagnosis. Nonetheless, even when DMT and linkage analysis are combined, it must be acknowledged that misdiagnoses remain possible (although extremely rare).

Wider implications of the findings: PGT-M is a valuable reproductive strategy for patients at high-risk of transmitting a single gene disorder. Linkage analysis is a valid strategy for PGT-M, but misdiagnoses are possible when testing relies entirely on such methods. These errors can be virtually eliminated by including direct testing of the mutation site.

Trial registration number: Not applicable

Study question: Can metabolic profiling predict embryos at risk of single gene defects and chromosomal abnormalities and how are these reflected in their ultrustructure?

Summary answer: Different metabolic profiles are observed between embryos with chromosomal abnormalities and monogenic disorders and normal embryos, linked to altered mitochondrial and other organelles' structure/function

What is known already: Down's syndrome embryos and Monosomy 21 embryos have previously been shown to have differential expression of metabolites compared to normal embryos, but limited studies, have investigated in detail the metabolic profiling of embryos with other abnormalities or those with monogenic disorders in comparison to chromosomally normal embryos or their reflection in their ultrustructure.

Study design, size, duration: 520 embryos were biopsied on day5 for PGT-A (n = 178-47 cycles) or on day3 for PGT-A (n = 178-33 cycles) and PGT-M (n = 164-24 cycles). Following transfer of normal embryos, spare embryos, rejected for transfer following day5 or day3 biopsy were processed for TEM (n = 60 day3 biopsied, n = 60 day5 biopsied/vitrified), 60 unbiopsied/vitrified embryos from egg donation cycles used as control. Culture media were collected from the embryos and analysed by hydrophilic interaction liquid chromatography tandem mass spectrometry (HILIC-MS/MS).

Participants/materials, setting, methods: PGT-A and PGT-M were performed in 2 IVF Units. Metabolic profiling was conducted in a Forensic Toxicology Laboratory by HILIC-MS/MS (100 metabolites). Ultrastructure analysis by TEM was carried out in an Academic Hospital and Histology/Embryology Laboratory following embryo fixation in 3% glutaraldehyde, 1% osmium tetroxide, washes in PBS and staining with 1% aqueous uranyl acetate.

Main results and the role of chance: The implantation rates (+ve hCG/ET) for the PGT-M cycles was 68.2% and the for the PGT-A (blastocyst and cleavage biopsy cycles) 64.5% and 65% respectively. Characteristic patient specific metabolic profiles after screening for >100 primary metabolites were observed which differed between normal embryos that had resulted in a viable pregnancy and aneuploid and chaotic embryos although it was more difficult to find clear patterns in embryos with monogenic disorders. Logistic regression analysis revealed a number of metabolites with high predictive value which in combination with embryo score could serve in the future as non-invasive markers for the detection of chromosomal abnormalities before embryo transfer. TEM analysis revealed differences in the quality of cells and organelle activity which were reflected in the embryo metabolic profiles. Abnormal but well developed hatching blastocysts had mainly cells with good mitochondrial morphology/ activity, nice Golgi apparatus and well developed rough and smooth endoplasmic reticulum but depending on the aneuploidy or gene mutation involved, inner cell mass cells with limited organelles and occasionally lipofuscin droplets in the trophectoderm were evident. Chaotic poor quality embryos showed a lower number of mitochondria, often with no cisternae, increased number of vacuoles, and frequently problems in junctions between cells.

Limitations, reasons for caution: Although metabolic profiles were compared between normal and abnormal embryos, all the normal embryos were transferred to the uterus or remain vitrified for clinical purposes. Therefore the ultrastructure analysis is based only on biopsied abnormal embryos and as control unbiopsied embryos from egg-donation cycles with high chance of being normal.

Wider implications of the findings: This study shows high implantation rates after PGT—M and PGT-A and identified distinct differences in the metabolic profiles of normal and abnormal embryos providing unique metabolites which in the future could serve as non-invasive biomarkers for the detection of abnormalities before embryo transfer.

[7]*University of Urbino Carlo Bo, Department of Biomolecular Sciences, Urbino, Italy*

Study question: Is morphological grade or presumed low-mosaicism status the most impactful parameter on live birth rate (LBR) when selecting the embryo to transfer in PGT-A cycles?

Summary answer: Among euploid/presumed low-mosaic embryos, morphology provides a better selection parameter for improving live birth in PGT-A cycles.

What is known already: NGS-based technologies enable the detection of intermediate chromosomal copy number (CN) values, which are commonly interpreted as embryonic chromosomal mosaicism. So far, studies showed that low morphological grade blastocysts are associated with poorer prognoses. Prospective blinded trials also showed that embryos displaying putative mosaic profiles produce comparable clinical outcomes to uniformly euploid ones. Nonetheless, scientific societies suggest different approaches on embryo prioritisation: PGDIS and COGEN advise a selection based on presence of mosaicism, while ESHRE suggests parallel evaluation of mosaicism and morphology. However, the combined effect of morphology and mosaicism on live birth rate (LBR) hasn't yet been thoroughly investigated.

Study design, size, duration: This retrospective multisite cohort analysis is based on a euploid/low-mosaic non-selection study, where the presumed mosaicism was not disclosed to clinics and did not affect the embryo selection procedure. It includes 2,339 consecutive IVF/PGT-A treatments (January2018-December2021) that led to 3,999 transferable blastocysts (euploid or presumed mosaic <50%) and resulted in 2,621 frozen single embryo

transfers (SETs). Morphological (i.e., good/poor quality) and chromosomal (i.e., euploid/mosaic) features were assessed. Clinical outcomes were followed up for each subgroup.

Participants/materials, setting, methods: Morphological grading was assessed using Gardner's criteria, <BB for poor-quality and >BB for good-quality embryos. PGT-A analysis and CN values calculations were performed on IonTorrentS5 and Ion-Reporter software (ThermoFisher). Based on raw NGS data, CN variations <30% and 30%-50% were internally categorised euploidy and mosaicism, respectively. Nevertheless, embryos belonging to either category were reported to clinics as euploid. The association between morphology, chromosomal status, and LBR was evaluated using Fisher's exact test and multivariate analysis.

Main results and the role of chance: In this study population, low-mosaicism had an incidence of 15.8% (N = 630/3,999; 95%CI:14.7-16.9). Overall, LBR and miscarriage rate did not differ between euploid and presumed mosaic SETs: 45.0% vs. 44.8% (P=NS), and 11.2% vs. 13.2% (P=NS), respectively. Also, euploid and presumed mosaic embryos showed similar incidence of poor morphology (7.4% vs. 9.7%; P=NS). In the good-quality category, LBR and miscarriage rate were 46.2% vs. 44.8% (P=NS), and 11.3% vs. 13.1% (P=NS) for euploid and presumed mosaic embryos, respectively. In the poor-quality category, LBR was 21.0% vs. 23.8% (P=NS), respectively; whilst miscarriage rates could not be compared due to insufficient number of cases across the whole morphological category (N = 4/33). Accordingly, the focused scenario that employed poor-quality uniformly euploid embryos instead of good-quality mosaic embryos showed the highest impact on LBR (21.0% vs. 44.8%; $P < 10^{-5}$). Finally, the proportion of cases where both selection strategies (i.e., mosaicism vs. morphology) could be applied accounted for 6.1% (N = 44/717; 95%CI:4.6-8.1) of all cycles where >1 transferable embryo was available (N = 717/2,339).

Limitations, reasons for caution: The results were obtained through the analysis of raw NGS data independent from any proprietary diagnostic algorithm or chromosome-specific consideration commonly used by PGT-A laboratories. These findings concern putative whole-chromosome mosaic aneuploidies only and cannot be extended to segmental mosaic configuration. Follow-up studies in prenatal diagnosis are needed.

Wider implications of the findings: This study suggests that, when selecting embryos for transfer, morphological grading should be considered as a higher criterion than low-mosaic conformation (i.e., mosaicism <50% of copy-number). Reporting mosaicism based on intermediate copy-number categorization ranges <50% appears to provide no clinical utility in the current technological landscape.

O-290 Clinical utility of putative mosaicism detected using concurrent copy-number and genotyping PGT method: outcomes from multisite, prospective, non-selection study including 9828 single embryo transfer cycles

D. Babariya[1], P. Gill[2], X. Tao[3], Y. Zhan[3], M. Figliuzzi[4], M. Werner[5], C. Jalas[3], A. Capalbo[4]

[4]*Juno Genetics Italy, Reproductive Genetics, Rome, Italy*
[5]*IVIRMA, Reproductive Endocrinology and Infertility, Eatontown- NJ, U.S.A.*

Study question: What is the clinical utility and associated outcomes of mosaic whole chromosome or segmental aneuploidies detected using concurrent copy-number and genotyping analysis in PGT-A cycles?

Summary answer: Although high-level whole-chromosome mosaicism is linked to reduced sustained implantation, it has limited clinical significance in PGT-A cycles when co-evaluated with other clinical/ embryological factors

What is known already: NGS-based PGT-A can detect intermediate chromosomal copy number (CN), commonly interpreted as mosaic chromosomal aneuploidies in embryos. A prospective non-selection approach is the most effective way to assess the clinical utility of reporting putative mosaicism findings in PGT-A, wherein the presence of mosaicism is not disclosed and does not influence embryo selection. Conflicting results have been reported previously, possibly due to technological limitations in mosaicism assessment or retrospective analysis methods. This study reports the results of the largest multisite prospective non-selection clinical study examining the predictive value of whole-chromosome and segmental mosaicism, assessed through combined CN and genotyping data analysis.

Study design, size, duration: A multisite study involving seven IVF clinics was conducted from Feb 2020 to Oct 2022, including 6951 patients and 9828 single embryo transfers. The study involved a prospective non-selection approach, where embryos suspected of having whole chromosomal or segmental mosaicism were reported as negative for non-mosaic aneuploidies. Embryos were chosen for transfer based solely on standard morphological features. The primary outcome was sustained implantation rate (SIR) defined as pregnancy continuing beyond 8 weeks of gestation.

Participants/materials, setting, methods: In this study, the trophectoderm biopsies were analyzed using a custom, targeted NGS assay that examined approximately 5000 loci across the genome, providing genotyping information to support aneuploidy classification. Mosaicism was identified by any copy number deviation from the expected two copies (LogR plots) and confirmed by corresponding SNP B-allele frequency (BAF) patterns. Confounding factors, such as clinical and embryological variables, were controlled for in the multivariate analysis.

Main results and the role of chance: The average female age in this cohort was 34.9 years (SD = 4.1), with aneuploidy rate of 30% in embryos and SIR of 61.2%. Of the embryos transferred, 6.5% (636/9828) were whole chromosomal mosaic (WCM) only; 9.6% (947/9828) were segmental mosaic (SM) only and 1% (83/9829) were a combination of WCM and SM. The rate of putative mosaicism ranged from 15%-89%. The SIR of embryos in the control group (non-mosaic), SM and WCM were 62% (5190/8328; 95%CI), 58% (549/947;95%CI) and 50.3% (320/636; 95%CI P < 0.01) respectively. A logistic model found that the level of WCM was associated to SIR, along with other embryological and clinical factors. In particular, WCM with a CN difference >50% as well as poor embryo morphology were associated with lower SIR (OR = 0.5; 95% CI:0.32-0.76), but low-level (<50%) mosaicism was not significant (NS). Notably, female age (OR = 0.98; 95% CI:0.97-0.99 per year), BMI (0.98; 95% CI:0.98-0.99) and previous ET failures (OR = 0.58; 95% CI:0.5-0.68) were strongly associated with SIR. A predictive model, taking into account all relevant variables, yielded a significant stratification of SIR, from 43% to 68%. Given the low incidence of WCM in our clinical setting, the multivariate SIR prediction (AUC) was 0.580 without WCM and 0.585 with mosaicism included.

Limitations, reasons for caution: This study did not have prenatal and post-natal data available at the time of the abstract's writing, hence conclusions about these outcomes wasn't possible. Despite the large sample size, chromosome specific analysis was not feasible. Furthermore, this study's data is platform-specific and cannot be translated to other PGT-A assays.

Wider implications of the findings: In this non-selection study, WCM of > 50% variation was associated with lower SIR. However, high-level WCM has a minimal overall impact on SIR when co-evaluating with other clinical/ embryological parameters. Decisions on reporting criteria for these findings must weigh the risk of discarding potentially viable embryos with substantial reproductive potential.

O-291 Clinical Application of Noninvasive PGT for Patients with Recurrent Pregnancy Loss or Repeated Implantation Failure

N. Li[1], J. Zhao[2], H. Xi[2], Y. Yao[3], S. Lu[1]

[1]Yikon Genomics, Global Business, Suzhou, China
[2]The Second Affiliated Hospital of Wenzhou Medical University, Department of Obstetrics and Gynecology, Wenzhou, China
[3]Yikon Genomics, Department of Clinical Research, Suzhou, China

Study question: Has noninvasive PGT been allied with the patients experiencing recurrent pregnancy loss (RIF) and recurrent implantation failure (RPL)? What are the clinical beneficiaries?

Summary answer: Embryo selection through noninvasive PGT can reduce the miscarriage rate in patients experiencing RPL and improve the clinical pregnancy rate in patients experiencing RIF.

What is known already: Chromosomal abnormalities exist in early human embryos, especially in patients with RPL and RIF. Therefore, embryos are usually evaluated through pre-implantation genetic testing for aneuploidy (PGT-A). However, a biopsy is an important concern for undetermined health risks. Meanwhile, the researchers observed genomic DNA contents in the embryo culture medium. Since then, multiple studies have been published using culture medium for analyzing chromosomal ploidy. In 2016, Xu et al. first reported a noninvasive chromosome screening (NICS) assay using a spent blastocyst culture medium. Nevertheless, the clinical application of NICS has not been evaluated in patients experiencing RPL or RIF.

Study design, size, duration: We designed a retrospective cohort study including 303 subjects from July 2018 to May 2021, according to the records of the Reproductive Centre at the Second Affiliated Hospital of Wenzhou Medical University.

Patients experiencing RPL or RIF who received the NICS for aneuploidy were included in the NICS group, while those who underwent conventional morphology embryo transfer during the same period were included in the non-NICS group.

Participants/materials, setting, methods: We included women with a history of RPL (≥2 pregnancies) or RIF (≥3 implantations), exclusion criteria were antiphospholipid syndrome (APS), diabetes, hypothyroidism, or other severe complications.

Routine IVF/ICSI was performed based on sperm quality. The embryos were placed in droplets. Approximately 30 mL of blastocyst medium from each embryo was transferred into cell lysis buffer. Whole-genome amplification was performed using culture media, followed by library preparation using ChromInst (Yikon Genomics; EK100100724 NICS Inst Library Preparation Kit).

Main results and the role of chance: For the patients experiencing RPL, the miscarriage rate per FET was significantly lower in the NICS group than in the non-NICS group (17.9% vs. 42.6%), whereas the ongoing pregnancy rate (40.7% vs. 25.0%) and live birth rate (38.9% vs. 20.6%) were significantly higher in the NICS group compared to the non-NICS group. Nevertheless, no differences were identified in pregnancy rates per patient between the NICS and non-NICS groups (49.6% vs. 44.9%).

For the patients experiencing RIF, the pregnancy rates per FET were significantly higher in the NICS group than in the non- NICS group (46.9% vs. 28.7%), whereas the live birth rate and ongoing pregnancy rate per FET and per patient were no significant difference in the NICS group than in the non-NICS group. Nevertheless, no differences were identified in the miscarriage rate per clinical pregnancy between the NICS and non-NICS groups (23.3% vs. 25.9%).

Limitations, reasons for caution: As a retrospective study, patients in the NICS groups had different clinical prognoses than those in the non-NICS groups, introducing bias in the study results.

Wider implications of the findings: Non-invasive PGT can be used not only for aneuploidy detection but also for a comprehensive evaluation of morphology and DNA concentration, mosaic ratio, resolution, etc. The accumulation of clinical outcomes can also be combined with the clinical data of patients as an index to predict the clinical outcomes of embryos.

[3]University Hospital of Caremeau-, Reproductive Medicine Department, Nimes, France
[4]University Hospital of Caremeau, Biostatistics- Clinical Epidemiology- Public Health Innovation and Methodology Laboratory, Nimes, France
[5]CHU and University of Montpellier, Department of Reproductive Biology, Montpellier, France

Study question: Does ovulation trigger enhance pregnancy rate in a natural cycle (NC) for frozen embryo transfer (FET)?

Summary answer: Pregnancy rates after a FET are similar in a natural cycle with detection of a spontaneous LH surge or with a triggered ovulation.

What is known already: Several studies have explored whether one approach might appear to be more beneficial in terms of pregnancy or live birth rates, but with inconsistent results. Thus, the best protocol to identify the time of ovulation in NC and to plan the FET is still undefined.

Study design, size, duration: This was a bicentric, two-arm, randomized, controlled and open-label trial, including 108 patients for 18 months. In the spontaneous-NC group, the LH surge was defined as a rise of the serum LH level at least three times above the basal LH serum value with a serum progesterone level three days after the LH surge above 3 ng/mL.

Participants/materials, setting, methods: Patients included were aged 18- to 39-year-old, had regular cycles and were planned for an autologous frozen day-5 blastocyst transfer in a NC. They did not have endometriosis stage AFSr 3 nor 4 nor adenomyosis. Fifty-four patients per group were included. In the modified-NC group, a spontaneous LH surge was observed in 16 women before the hCG-trigger could be administrated: they were re-allocated to the spontaneous-NC for the per-protocol (PP) analysis.

Main results and the role of chance: Patients characteristics were comparable in both groups. Pregnancy rates were similar in the spontaneous-NC and the modified-NC group in the intention-to-treat (ITT) (41.3 versus 37.8% respectively, $p = 0.85$) and in the PP analysis (39.3% versus 40% respectively, $p = 0.9$). Ongoing pregnancy, miscarriage and live birth rates were also similar. Significantly more visits were needed in the spontaneous-NC (3.4 ± 0.81 versus 2.59 ± 1.0, $p < 0.0001$ in the ITT analysis and 3.18 ± 0.93 versus 2.63 ± 1.03, $p = 0.0064$ in the PP analysis).

Limitations, reasons for caution: Due to group redistribution (spontaneous LH surge before hCG trigger), the number of subjects in the modified-NC group is low for the PP analysis. This may reduce the power of the trial which may fail to detect a small difference.

Wider implications of the findings: The results reinforce previous data that showed similar efficacy of the s-NC and the m-NC. This allows the patient to choose from several options depending on her preference.

O-293 An Artificial Intelligence Based Approach for Selecting the Optimal Day for Triggering in Antagonist Cycles

M. Youngster[1], S. Reuvenny[2], A. Luz[3], R. Hourvitz[4], M. Baum[5], M. Ettie[5], A. Hourvitz[1]

[1]Shamir Medical Center, IVF unit- Department of Obstetrics and gynecology- Tel Aviv University, Ber Yaakov, Israel
[2]FertilAI LTD, Research and Development, Ramat Gan, Israel
[3]FertilAI LTD, Chief Technology Officer, Ramat Gan, Israel
[4]FertilAI LTD, Chief Executive Officer, Ramat Gan, Israel
[5]Chaim Sheba Medical Center & Herzliya Medical Center, IVF unit- Department of Obstetrics and Gynecology- Tel Aviv University, Ramat Gan, Israel

Study question: Can a machine learning (ML) algorithm suggest an optimal trigger day for maximizing the number of mature (MII) oocytes retrieved during an antagonist protocol cycle?

Summary answer: Using ML algorithm for trigger day selection may increase the mean number of MII oocytes and usable embryos by 3.6 and 1.1 per cycle respectively.

What is known already: ML has been increasingly used in the field of reproductive medicine, mainly in lab related technologies such as embryo selection. Only a few studies, aimed at improving clinical decision making, were published. A recent study used ML to optimize trigger day selection based on a retrospective analysis, showing an increase of 2.3 MII oocytes and 1.0 usable embryo.

Study design, size, duration: A retrospective cohort study including data of 9,622 antagonist protocol cycles performed between August 2017 to November 2022. The evaluation of the ML algorithm was conducted using a test dataset including the following quality groups: 1. "Freeze all- oocytes" cycles – a unique population of patients mostly for social fertility preservation. 2. "ICSI only" cycles – for maturation rate evaluation 3. "Fertilize all" cycles including IVF and ICSI, for evaluation of the number of embryos.

Participants/materials, setting, methods: The ML algorithm suggested optimal trigger days for maximizing the number of MII oocytes retrieved by considering the MII prediction, prediction errors and outlier detection results. The model suggested one, two, or three days as trigger options, depending on the difference in potential outcomes. It recommended the days that have a 10% higher prediction of MII oocytes with a confidence level of over 50% compared to less optimal options if they exist.

Main results and the role of chance: To evaluate the performance of the management algorithm, it was applied to cycles in the test sets. For each cycle, the algorithm provided a suggestion for trigger days, and this was compared to the actual trigger day chosen by the physician. When the day chosen by the physician was one of the algorithm's suggestions, the result was labeled as "correct", otherwise it was labeled as "incorrect".

Comparing the "correct" and "incorrect" groups, using the trigger management algorithm resulted in a higher number of total and MII oocytes retrieved, 2PN and usable embryos. Specifically, when using the algorithm in the "Freeze All" test set, an average increase of 4.8 oocytes and 3.4 MII oocytes retrieved in the "correct" group (consisting 36.2% of the quality group subset) compared to the "incorrect group" (63.8%). In the "ICSI-only" test set, the algorithm resulted in an average increase of 4.5 oocytes, 3.8 MII oocytes, 2.4 2PN and 1.1 usable embryos in the "correct" group (26.8%) compared to the "incorrect group" (73.2%). Lastly, in the "Fertilize all" test set, the algorithm resulted in an average increase of 3.6 oocytes, 2.1 2PN, and 0.9 usable embryos in the "correct" group (25.1%) compared to the "incorrect group" (74.9%).

Limitations, reasons for caution: The trigger management algorithms' decision-making is based solely on the predicted number of MII oocytes to be retrieved. Moreover, it was developed and applied exclusively for antagonist cycles.

Wider implications of the findings: The trigger management algorithm may improve oocyte yield and IVF outcomes in antagonist cycles. Moreover, provision of two or three trigger options allows for more flexibility when choosing the trigger day and enables taking into account other factors without negatively affecting the outcome.

Trial registration number: NA

Abstract citation ID: dead093.358

O-294 Dual trigger versus hCG-only trigger in ICSI patients: an analysis of 8500 cycles

C. Blockeel[1], M.P. Agius[2,3], S. De Rijdt[2], H. Tournaye[2], M. De Vos[2], P. Drakopoulos[2]

[1]Brussels IVF, Centre for Reproductive Medicine- Universitair Ziekenhuis Brussel, Grimbergen, Belgium
[2]Brussels IVF, Centre for Reproductive Medicine- Universitair Ziekenhuis Brussel, Brussels, Belgium
[3]Mater Dei Hospital, Department of Obstetrics and Gynaecology., Malta, Malta

Study question: Among patients undergoing ovarian stimulation for ICSI, does dual trigger with hCG and GnRH agonist offer any benefit over mono trigger with hCG alone?

Summary answer: Dual trigger is associated with a higher number of mature oocytes without any impact on the pregnancy rate.

What is known already: In ART cycles, final oocyte maturation and resumption of meiosis are generally triggered by the administration of hCG as a surrogate for the natural LH surge. Several studies have investigated the role of a combination of a bolus of GnRH agonists and hCG to mimic the natural peak of endogenous LH and FSH, without clear answers regarding clinical benefit. A meta-analysis showed highernumbers of good-quality embryos and increased ongoing pregnancy rate after dual trigger and a recent systematic review demonstrated significantly higher live birth rate (LBR) per cycle after administration of dual trigger compared to hCG-only trigger.

Study design, size, duration: The study was a retrospective, single-centre cohort study. In this study, 8,525 ICSI cycles were included between January 2017 and April 2022 at a tertiary referral University Hospital. We included all patients undergoing ICSI in a GnRH antagonist ovarian stimulation cycle. The mono trigger consisted of recombinant or highly purified urinary hCG. In the dual trigger group, a bolus of GnRH agonist was combined with the hCG trigger.

Participants/materials, setting, methods: Our cohort of 8,525 cycles was divided into two groups: Group A, the mono trigger group, (7,022 cycles), and Group B, the dual trigger group (1503 cycles). Patients who underwent IVF, pre-implantation genetic testing, oocyte donation, and fertility preservation were excluded. Patients with uterine anomalies and endocrine disorders were also excluded, as well as patients who received a triptorelin-only trigger because of hyperresponse.

Main results and the role of chance: There was no difference in the mean age between the dual vs mono trigger cohorts (35.93 $\pm$ 4.90 vs 35.52 $\pm$ 4.85). The most common indication for ART was male factor infertility in both groups (21.36% in group B vs 27.11% in group A). Stimulation was shorter in the dual trigger cohort (10.41 vs 12.08 $p = 0.04$). The total number of cumulus oocyte complexes (8.26 $\pm$ 5.32 vs 7.45 $\pm$ 4.68, $p < 0.001$), mature oocytes (6.39 $\pm$ 4.15 vs 5.99 $\pm$ 3.80, $p = 0.006$) and fertilized oocytes (4.79 $\pm$ 3.59 vs 4.33 $\pm$ 3.27, $p = <0.001$) was higher in the dual trigger group compared to those in the mono trigger group. Day 5 embryo transfer was more prevalent in the dual trigger group (46.07% vs 33,84%, $p < 0.001$). Embryo utilization rate was higher in group A (61.37% $\pm$ 31.98) than in group B (53.47% $\pm$ 30.91 $p = <0.001$). Ongoing regnancy rate was similar in both groups (27.29% in group A vs 27.08% in group B). Pearson chi2, Mann Whitney and logistic regression tests were used for the analysis.

Limitations, reasons for caution: In spite of the large sample, this study is retrospective and holds the possibility of unmeasured confounders.

Wider implications of the findings: Although a dual trigger may increase the number of mature oocytes, this does not translate into a higher pregnancy nor live birth rate. Reduced oocyte competence of the "surplus" oocytes may underlie this observation. Further research should identify specific subgroups that may benefit from dual trigger across meaningful outcome parameters.

Trial registration number: not applicable

O-295 Dual trigger does not improve reproductive outcomes in advanced maternal age women

P. Drakopoulos[1,2], M. Dimitraki[2], M. Kiriakidis[2], N. Anesidis[2], A. Aslanidis[2], D. Michalakis[2], A. Papatheodorou[2], A. Chatziparasidou[2], N. Christoforidis[2]

[1]*UZ Brussel, Center for Reproductive Medicine, Brussels, Belgium*
[2]*Embryolab, IVF clinic, Thessaloniki, Greece*

Study question: Could dual trigger increase oocyte yield and maturation rate in women of advanced maternal age (≥ 40) undergoing IVF?

Summary answer: Dual trigger does not result in higher oocyte yield or maturation rates compared to hCG monotrigger

What is known already: Advanced maternal age is related to poor ovarian response (POR) and remains a major therapeutic challenge in routine IVF practice, because of the association with low live birth rates and high cancellation rates. hCG is used at the end of controlled ovarian hyperstimulation as a surrogate LH surge to induce final oocyte maturation. Recently, the co-administration of GnRH agonist and hCG for final oocyte maturation (dual trigger) has been suggested to improve IVF outcome (by improving oocyte quantity and quality) in normal responders, while evidence in poor responders remains controversial.

Study design, size, duration: This is a retrospective cohort study including patients attending a private IVF clinic from 1st January 2018 until 1st June 2022.

Participants/materials, setting, methods: All women who underwent IVF/ICSI in antagonist protocol in our center were included. Patients may have undergone triggering of the final oocyte maturation either with 250mcg of rhCG or 0.2 mg of GnRH agonist. Mature oocytes were inseminated using ICSI.

Main results and the role of chance: In total, 2242 patients were included, 454 (20.2%) in the rhCG group and 1788 (79.8%) in the dual trigger group. There was no significant difference in female age [41.3 (1.12) vs 41.3 (1.19), p value 0.94]. Total stimulation units and duration were also comparable between groups. The number of oocytes and MII oocytes did not differ significantly between rhCG and dual trigger group [5.8 (4.1) vs 6.3 (4.7) and 4.7 (3.3) vs 4.9 (3.4), p = 0.15 and 0.49, respectively]. Maturation rates were similar 81.7% (22.4) and 79.8% (23.5), p = 0.15, as well as fertilization rates (defined as the number of oocytes fertilized divided by the total number of cumulus-oocyte complexes recruited) [57% (29.7) vs 58.8% (29.4), p value=0.2]. Embryo utilization rates (defined as the total number of embryos transferred and cryopreserved divided by the number of oocytes fertilized) were comparable between the two arms: 69.7% (34.2) vs 70% (33.9), p value =0.22.

Multivariate Poisson regression analysis adjusting for relevant confounders (AMH, total stimulation units) showed that the type of triggering strategy (dual trigger vs rhCG) was not associated with either the number of MII oocytes (coefficient 0.2, p value=0.24) or maturation rates (coefficient -1.8, p value 0.12).

Limitations, reasons for caution: The main limitation is the retrospective design of our study, with an inherent risk of bias.

Wider implications of the findings: To the best of our knowledge, this is the largest study evaluating dual trigger strategy in advanced maternal age women. Our data demonstrate that dual trigger cannot improve the outcome of low prognosis women and should not be used as a panacea for all IVF patients.

O-296 Progesterone level is an alternative marker to detect ovulation time in natural cycle frozen-thawed embryo transfers

T. Aydin[1], N. Koroglu[1], E. Kose[2], N. Albayrak[1], M.A. Insel[3]

[1]*Acıbadem Mehmet Ali Aydinlar University School of Medicine, Obstetrics ang Gynecology, Istanbul, Turkey*
[2]*Sakarya University Faculty of Medicine, Public Health, Sakarya, Turkey*
[3]*Yildiz Technical University, Chemical Engineering, Istanbul, Turkey*

Study question: Do serum progesterone or LH levels better predict the optimal timing for embryo transfer in true natural cycle frozen-thawed embryo transfers (NC-FET)?

Summary answer: Performing embryo transfer according to serum progesterone levels (PL) had similar ongoing pregnancy rates compared to embryo transfer according to serum LH levels.

What is known already: With efficient and safe embryo vitrification techniques, there is an increasing trend in frozen-thawed embryo cycles (FET) over fresh cycles. FET protocols are programmed cycle, NC-FET and modified NC-FET. NC-FET is increasing in popularity, since it is associated with favourable obstetric and perinatal outcomes. In NC-FETs, ovulation time is the critical parameter for synchronization of embryo and endometrium. In the literature, LH surge is the most commonly used test to define ovulation time.

Study design, size, duration: This prospective cohort study included 183 NC-FET cycles in an IVF clinic between March 2022 and November 2022.

Main outcome measure is ongoing pregnancy.

Participants/materials, setting, methods: 183 subfertile women aged between 18-40, having regular menstruation with a cycle length between 24-38 days are included. Protocol for NC-FET included serial hormone measurements and ultrasound monitoring when the dominant follicle reached the diameter of 15-16 mm. Serum LH level ≥15 IU/l defined as 'ovulation -1' in Group 1 and blastocyst embryo transfer was performed after 6 days. Serum PL > 1 ug/ml was defined as the 'ovulation day' in Group 2.

Main results and the role of chance: There were no significant differences in baseline characteristics including female age, female body mass index, infertility duration, infertility diagnosis and number of failed IVF cycles between two groups. Also, cycle characteristics regarding endometrial thickness, number of embryos transferred, embryo quality and PLs at transfer day were similar. The overall clinical pregnancy was 59.6% and ongoing pregnancy was 50.8%. The implantation rate was 61.7%. The clinical pregnancy and ongoing pregnancy of Group 1 and Group 2 were 49.5%, 50.5% and 47.3%, 52.7%, respectively (p > 0.05). PLs in order to detect ovulation time were calculated according to a mathematical modelling (PL(Ov)=a1 eb1 Ov)(Ov:ovulation day; a1,b1:regression coefficients; e:euler number≅2.718) described in our previous study. Embryo transfer timing was planned after 5,4 or 3 days based on PLs calculated by modelling.

Limitations, reasons for caution: Since this is the first study planning embryo transfer in NC-FET based on progesterone levels, sample size should be increased and also serial change of progesterone levels were unknown in women >40 years of age.

Wider implications of the findings: Progesterone has a particular increasing pattern that enables ovulation day prediction accurately and may be used instead of serum LH levels in timing of embryo transfer.

O-297 Contribution of Frozen Embryo Transfer Cycles to ICSI Clinical Outcomes in Male Factor Infertility

J. Johal[1], P. Xie[1], S. Cheung[1], Z. Rosenwaks[1], G. Palermo[1]

[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.*

Study question: What is the benefit of adding frozen embryo transfer (FET) cycles to ICSI clinical outcomes in male factor infertility?

Summary answer: FET carried out on spare embryos that reached blastocyst stage remarkably contributed to additional clinical pregnancies in ICSI cycles for male factor infertility.

What is known already: Current trends in reproductive medicine lean toward full-preimplantation development and eventually to PGT-A to select a single euploid embryo for transfer. The utilization of this approach, while beneficial in most couples, is not ideal for male factor infertility due to the tendency of being characterized by impaired embryo development. So, we wonder if the utilization in FET cycles of leftover embryos that reached to blastocyst stage or those that eventually reached day 5 for aneuploidy testing contributed to the clinical outcomes.

Study design, size, duration: In the past 7 years, we included 22,289 couples who underwent ICSI while the large majority (84.8%) received a fresh embryo transfer, of which 70.9% were transferred at day 3. Leftover embryos, together with those euploid after PGT-A at blastocyst stage, were replaced in subsequent FET cycles. The clinical outcomes including clinical pregnancy rate (CPR) and deliveries were compared between the fresh embryo transfer and those after FET in total and after PGT-A.

Participants/materials, setting, methods: Couples with male factor underwent ICSI in standard fashion using exclusively ejaculated sample. For fresh embryo transfer cycles, embryos were transferred either at day 3 or at day 5. For FET cycles, embryos were cultured up to exclusively blastocyst stage and cryopreserved by vitrification. For aneuploidy, NGS was carried out for PGT-A. FET was carried out in natural or programmed cycles.

Main results and the role of chance: In the cohort underwent fresh embryo transfer, 18,896 couples underwent 37,751 ICSI cycles, where 322,916 oocytes were injected and 243,768 (75.5%) fertilized. Additionally, 3,393 patients received 4,712 FET in total with a fertilization of 69.8% (46,163/66,171) that did not differ from the fresh transfer group. The number of average embryos transferred in fresh cycles was 2.4 ± 2 while FET was carried out exclusively on single embryo. Fresh transfer yielded 37.3% (14,087/37,751) CPR, while overall FET cycles achieved a higher CPR at 52.2% (2,462/4,712, $P<0.0001$). Similarly, the delivery rate in fresh cycles was 31.8% (12004/37751) and became 45.5% (2145/4712) in the FET ($P<0.0001$).

To identify the advantage of selecting a single euploidy embryo, we compared FET on leftover unscreened blastocyst to those that were planned for PGT-A. Spare embryo transfers involved 1774 patients in 2282 cycles with a fertilization rate of 67.7% (18,905/27,937). For the PGT-A cycles, 1619 couples in 2430 cycles achieved a comparable fertilization rate of 71.3% (27,258/38,234), In this comparison, the FET on spare unscreened embryos achieved a CPR at 47.0% (1,072/2,282) while in the PGT-A group reached CPR at 57.2% (1390/2430, $P<0.0001$). Similarly, the delivery rate was 37.6% (857/2,282) in the FET and PGT-A was 53.0% (1,288/2,430) ($P<0.0001$).

Limitations, reasons for caution: The comparison is retrospective and is carried out on male factor infertility where day 3 embryo transfer were performed almost exclusively on fresh cycle to overcome poor embryo development. Nonetheless, those spare embryos that reached blastocyst stage and those that electively underwent aneuploidy testing significantly contributed to enhance clinical outcomes.

Wider implications of the findings: ICSI can overcome most of male infertility; however, the risk of impaired embryo development proposes a transfer at cleavage stage. The advanced embryo culture condition together with time-lapse allowed us to monitor embryos up to the blastocyst stage that once transferred, improving clinical outcomes, especially for embryos with confirmed euploidy.

O-298 Poor semen parameters alter embryo morphokinetic patterns during preimplantation development but do not compromise clinical outcomes

M. Petrolo[1], F. Zambelli[1], I. Miguel-Escalada[2], M.J. Zamora[3], A. Rodríguez[4], R. Vassena[1], M. Popovic[1]

[3]*Clinica EUGIN, Clinical Embryology, Barcelona, Spain*
[4]*EUGIN group, Corporate Medical, Barcelona, Spain*

Study question: Does semen quality affect preimplantation development and clinical outcomes in ICSI cycles using donor oocytes?

Summary answer: Poor semen parameters led to altered morphokinetic parameters during preimplantation development but did not compromise blastocyst quality nor clinical outcomes in oocyte donation cycles.

What is known already: The quality of semen used for in vitro fertilization (IVF) may compromise the kinetics and morphology of developing embryos, ultimately impairing implantation and reducing live birth rates. Such effects are particularly pronounced when testicular or epididymal spermatozoa are used for IVF treatment. However, current studies assessing the impact of poor semen parameters on embryo development and clinical outcomes are often confounded by the use of oocytes from infertile patients. Performing such evaluations in oocyte donation cycles will provide more definitive insights into the role of semen during preimplantation development.

Study design, size, duration: This retrospective study included 616 embryos from 99 oocyte donation ICSI cycles, performed between February 2018 and July 2019. We compared embryo morphokinetics and clinical outcomes (cumulative pregnancy and live birth rates) across three groups with variable semen parameters. These included donor semen (control group, DD, $n=294$), partner sperm obtained by testicular sperm extraction (TESE group, $n=72$) and partner semen with altered parameters (including poor concentration, motility and morphology, ALT group, $n=250$).

Participants/materials, setting, methods: We assessed several morphokinetic parameters, including second polar body extrusion (tPB2), pronuclei appearance (PN1a, PN2a), 2-3-4-5-8-cell stages (t2 to t8), start of blastulation (tSB) and blastocyst formation (tB). Kaplan-Meier survival curves were built for each parameter per study group. Survival curves were analysed by Cox regression. Qualitative parameters (even size PN and blastomeres, percent fragmentation, abnormal cleavages, blastocyst grade) were assessed using a Chi-Squared test, while Fisher's exact test was used to evaluate clinical outcomes.

Main results and the role of chance: Interestingly, TESE embryos reached several developmental stages faster than the DD group: tPB2 (3.03 vs. 3.08, $p<0.001$), PN1a (5.55 vs. 6.19, $p<0.001$), PN2a (6.78 vs. 7.36, $p<0.001$), tPNf (21.30 vs. 22.20, $p=0.001$), t3 (34.02 vs. 35.79, $p=0.016$), t4 (35.90 vs. 36.92, $p=0.015$), t5 (46.70 vs. 48.07, $p=0.036$), t8 (52.48 vs. 55.28, $p=0.049$), tSB (85.53 vs. 94.62, $p<0.001$) and tB (104.09 vs. 106.60, $p=0.002$). ALT embryos were faster in early stages: PN1a (6.63 vs. 6.19, $p=0.005$), PN2a (7.84 vs. 7.36, $p<0.001$), t5 (48.12 vs. 48.07, $p=0.028$), t8 (55.57 vs. 55.28, $p=0.032$), but slower in the late stages: tSB (93.71 vs. 94.62, $p=0.001$), tB (105.60 vs. 106.60, $p=0.002$). Compared to DD, ALT and TESE embryos showed a lower rate of even pronuclei (ALT $p=4.6\times10^{-06}$; TESE $p=8\times10^{-05}$) and even blastomeres at the 2-cell (ALT $p<0.001$; TESE $p=0.006$) and 4-cell stage (ALT $p=0.004$; TESE $p=0.005$). Moreover, embryos derived from testicular sperm showed significantly higher fragmentation rates at the 8-cell stage ($p=0.005$), while no significant differences in the frequency of irregular divisions nor in the number of top-quality blastocysts were detected in ALT and TESE. Importantly, cumulative live birth rates per cycle were similar across all study groups (DD 31/53, ALT 31/51, TESE 8/11; $p>0.05$).

Limitations, reasons for caution: The main limitation resides in the retrospective nature of this study and the limited number of embryos in the TESE group. We also note variability in the testicular biopsy (obstructive and non-obstructive azoospermia) and non-normozoospermic diagnoses (oligozoospermia, teratozoospermia or asthenozoospermia), which may confound the analysis.

Wider implications of the findings: Although poor semen parameters significantly altered embryo morphokinetics, they did not compromise embryo quality, pregnancy or cumulative live birth rates, resulting in similar clinical outcomes as with double donation. Overall, our findings support the use of autologous sperm with donor oocytes, even in severe cases of male factor infertility.

O-299 Sperm DNA fragmentation by TUNEL influences live birth in egg recipients after euploid embryo transfer

F.M. Lozano[1], M. Hortal[1], B. Lledó[1], J.A. Ortiz[1], R. Morales[1], A. Bernabeu[2], R. Bernabeu[2]

[1]*Instituto Bernabeu of Fertility and Gynecology., Instituto Bernabeu Biotech., Alicante, Spain*
[2]*Instituto Bernabeu of Fertility and Gynecology., Instituto Bernabeu of Fertility and Gynecology., Alicante, Spain*

Study question: Does sperm DNA fragmentation (SDF) by TUNEL affect reproductive success measured as live birth rate (LBR) in egg recipients after euploid embryo transfer?

Summary answer: SDF increases miscarriage rates in egg recipients with PGT-A. Therefore, live birth rates depends on sperm DNA damage in egg recipients after euploid embryo transfer.

What is known already: Sperm DNA integrity is important for optimal fertilisation, implantation and pregnancy. Although controversial, several studies have shown that sperm DNA fragmentation correlates with adverse pregnancy outcomes in infertile men. Ooplasmic sperm DNA fragmentation repair mechanisms may occur in female gametes, mainly in young women. However, research on the impact of DNA fragmentation on LBR are limited. Also, chromosomally normal embryos analysed by PGT-A offers opportunity to isolate female factor and study male factor. The aim of this study is to assess whether high level of semen DNA damage has an impact on reproductive outcomes in terms of live birth rate.

Study design, size, duration: This is a retrospective study of 467 PGT-A cycles in egg recipients. The study population consists of infertile couples for euploid embryo transfer (February 2017-November 2022). Semen samples were obtained to measure DNA damage from 447 men. PGT-A was performed in 1831 blastocysts. Trophectoderm biopsies (d5/d6 blastocysts) were analysed by NGS (Veriseq Illumina). Embryos were frozen and 568 blastocysts transferred in the subsequent cycle. Conventional hormone replacement was used for endometrial preparation in recipient patients.

Participants/materials, setting, methods: Cohort study with 447 infertile couples attending to private fertility clinic undergoing ART with their autologous semen, donated oocytes and PGT-A. SDF was measured by Terminal-deoxyribonucleotidyl-ARTSferase-mediated dUTP Nodule End Labelling (TUNEL) assay using the FITC-labelled-dUTP in situ cell death detection kit (Roche). The cohort was divided into two groups according the DNA fragmentation index (DFI): high SDF group (DFI>20%) and normal SDF group (DFI≤20%). To evaluate reproductive outcomes Chi-square and Linear regression tests were used.

Main results and the role of chance: Of the 447 couples included (average paternal age 41.29 + 7.32 years), 66.5% of male partners had normal semen parameters. We reported high sperm DNA fragmentation in 8% of patients. Overall, the embryo aneuploidy rate was 31.7%. For the further statistical analysis confounding factors such as, female and male age, embryo quality, day of embryo biopsy were included. PGT-A analysis showed an aneuploidy rate of 32.1% in the high DNA fragmentation group and 30.3% in the normal DNA fragmentation group ($p = 0.453$). Regarding clinical data, the overall implantation rate was 34.9%. There was no significant difference between elevate DNA fragmentation and normal DNA fragmentation with respect to biochemical miscarriage rate (4.3% vs 7.6%, $p = 0.799$). Although not significant differences between groups, a lower implantation rate near to reach significance was found in the high SDF group (20.0% vs 34.4%, $p = 0.050$). Pregnancy and clinical pregnancy rates were significantly lower in the high DNA fragmentation group (26.1% vs 44.9%, $p = 0.042$; 21.7% vs 31.3%, $p = 0.044$;), respectively. Also, miscarriage rate was significantly higher in the high SDF group (40% vs 12.5%, $p = 0.014$). Therefore, the live birth rate was significantly lower in the high SDF group (13.0% vs 32.6%, $p = 0.024$).

Limitations, reasons for caution: Larger studies including a higher number of samples are needed to confirm the correlation observed between LBR in eggs recipients with semen DNA fragmentation. Those patients with a DFI higher than control values should be treated with antioxidants. The pregnancy outcomes should be analyzed after treatment of DNA fragmentation.

Wider implications of the findings: Our findings suggest that autologous semen DNA fragmentation influence in live birth rate in egg recipients. Our data show that live birth rates decreased in patients with a high DFI after PGT-A. This study confirms published studies in the literature showing that ART outcomes are affected by sperm DNA fragmentation.

O-300 Human sperm selection using cumulus oophorus complexes compared with conventional sperm preparation method on sperm quality and ICSI outcomes: A pilot study

G. Ruvolo[1], I. Camera[2], B. Ermini[2], F. Sapienza[2], M. Manno[1], A.M. Brucculeri[1], A. Biondo[1], A. Lo Bue[1], G. Falcone[1], C. Simonaro[1], E. Cefalù[1], M. Ermini[2], E. Cittadini[1]

[2]*CIPA-Centro Italiano di Procreazione Assistita, CIPA-Centro Italiano di Procreazione Assistita, Roma, Italy*

Study question: We compared a sperm selection protocol using cumulus oophorus complexes with a swim up preparation, evaluating the effects on sperm parameters and ICSI outcomes

Summary answer: Spermatozoa selected using cumulus oophorus complexes showed higher rates of normal morphology, good motility compared with basal semen and the traditional pellet swim up protocol.

What is known already: It is known that the head of a mature spermatozoa has a hyaluronan receptor that allows them to bind with hyaluronan acid. Cumulus oophorus complexes (COCs) extracellular matrix is made mainly by hyaluronic acid (HA). Various studies have confirmed the importance of COCs in fertilization, demonstrating that spermatozoa that are able penetrate through a layer of COCs are more likely to have a normal morphology and be more effective in producing acrosome reactions than spermatozoa that are not able to do. Moreover, these spermatozoa have been shown to have higher chromatin integrity and zona-binding capacity, resulting in increased fertilization competence.

Study design, size, duration: A prospective study was conducted between July and December 2022. A total of 50 participants were recruited for the study, randomly selected between patients attending ICSI. The patients were classified as group A when the sperms were selected using pellet swim up and COC selection and as group B when it was used pellet swim up treatment alone. Patients older than 39 years, with endometriosis or repeated IVF failure or severe male factor were excluded.

Participants/materials, setting, methods: 3 drops of 30 mlt aligned and connected each other were prepared, covered with mineral oil. In group A, in the middle drop, was transferred COC fragments, while the central drop was empty in group B. In the left drop were added 20 mlt of sperm suspension after swim up, and from the right drops were recovered the sperms after passing the middle drop with or without COC, that were used for ICSI treatment.

Main results and the role of chance: The aim of the study was to verify the effectiveness of COCs, collected after ovarian stimulation, in selecting the best sperms to be used in ICSI procedure. No statistical difference was found between group A and B in the median age of female patients, FSH/LH units administred, E_2 and endometrium thickness at triggering using hCG, in the sperm concentration, motility and normal morphology in the baseline seminal

samples. We found a statistical difference in the traditional seminal parameters comparing the two different treatments. In particular, we found an higher rates of sperms with rapid and progressive motility and normal morphology in group A between basal semen sample and after sperm selection using COC filter (86.7 vs 31.3%; 8.2 vs 4.4 %). We found a lower sperm concentration in group A vs group B after sperm treatment (2.3 vs 4.7 M/ml), and an higher rates of rapid progressive motility and normal morphology in group A vs group B (86.7 vs 38.6 %; 8.2 vs 4.6%). We found an higher but not statistically significative pregnancy and implantation rates in group A compared with group B probably because of the limited number of patients analyzed (25 vs 19.2 %; 25 vs 20.6%)

Limitations, reasons for caution: The study was conducted on a small participant cohort. We analyzed the traditional sperm parameters, but it is necessary to evaluate the chromatine integrity of the sperms after COC selection to confirm that the higher sperm competence in fertilization and embryo development could be based on a better genetic pattern

Wider implications of the findings: Data seem to demonstrate that the use of COC allows to select higher competent sperms if compared with traditional pellet swim up treatment. The clinical and biological ICSI outcomes seem to be improved by COC treatment but it is necessary to increase the sample size in future experimental trial

Trial registration number: not applicable

O-301 Can advanced sperm selection techniques improve blastocyst euploidy rate of abnormal sperm DNA fragmentation cases to the level of normal ones; prospective randomized controlled trial

E. Hasanen[1], M. Hozayen[1], A. Elshimy[1], Y. Hazem[1], H. Alkhader[1], H. Zaki[1]

[1]Ganin Fertility Center, IVF lab, Cairo, Egypt

Study question: To compare PGT-A outcomes of Physiological ICSI (PICSI) and magnetic activated cell sorting (MACS) sperm selection techniques to a control of normal sperm DNA fragmentation.

Summary answer: PGT-A outcomes did not differ between using normal sperm DNA fragmentation semen to the semen processed by PICSI or MACS.

What is known already: Sperm DNA fragmentation can negatively affects pre-implantation embryo development in all stages after ICSI. Advanced sperm selection techniques like PICSI and MACS are thought to be efficient to improve fertilization, cleavage, and blastocyst formation rates in cases with abnormal SDF. It has become evident that a blastocyst's aneuploidy is not only contributed by the oocyte,but can also be caused by the sperm.The relation between sperm selection techniques such as PICSI or MACS and blastocyst euploidy is not investigated yet.

Study design, size, duration: A prospective randomized controlled trial of 351 ICSI cycles in a private fertility center, from October 2019 to December 2022. Cases were included in the study if: female had ≥5 MII oocytes, male had abnormal sperm DNA fragmentation (SDF) index (>20% by TUNEL assay), all blastocysts (≥4BB) had trophoectoderm biopsy.

Participants/materials, setting, methods: Included cases were randomized on the day of ICSI to PICSI or MACS group, along with a control arm of cases with normal SDF needed for comparison. PGT-A was done using Illumina platform (Miseq), and the results were reviewed by artificial intelligence (Cooper Surgical). Cases were categorized according to the female age into 2 subgroups(<35, and > 35 years). Statistical analysis of all pre-implantation embryo development parameters and PGT-A results were done using SPSS.

Main results and the role of chance: We found no significant differences between the female age, male age, count, motility, SDF, no. mature oocytes between the studied groups.

Limitations, reasons for caution: The results included all pre-implantation embryo parameters but, subsequent post-implantation events like implantation, pregnancy and miscarriage rates will add more data about the competency of the resulted embryos.

Wider implications of the findings: The usage of advanced sperm selection techniques like PICSI or MACS has showed comparable results to that of normal SDF cases, through eliminating the adverse effects of SDF on ICSI and PGT-A outcomes.

Trial registration number: NCT05494216

O-302 Triploid conceptions are predominantly caused by female meiosis II errors and their risk increases with advancing maternal age

L. Picchetta[1], M. Figliuzzi[1], M. Poli[1], Y. Zhan[2], S. Caroselli[1], X. Tao[2], C. Jalas[2], A. Capalbo[1]

[1]JUNO Genetics Italia s.r.l., Reproductive genetics, rome, Italy
[2]Juno Genetics USA, Reproductive Genetics, Basking Ridge, U.S.A.

Study question: What are the incidence and origin of ploidy abnormalities in embryos derived from 2 pronuclei (2PN) zygotes, and is their risk linked to maternal age?

Summary answer: While embryo haploidy is usually due to male meiosis errors, triploidy is mainly caused by female meiosis II errors, whose incidence increases with maternal age.

What is known already: Normal fertilization is denoted by the appearance of 2PN 16-18 hours after insemination. Deviation from 2PN is considered evidence of abnormal fertilization and ploidy anomalies. Nonetheless, even 2PN embryos can be diagnosed with ploidy abnormalities during preimplantation genetic testing (PGT). The incidence of 3PN has already been linked to advanced maternal age. However, no conclusive and well-powered studies have yet investigated the incidence, origin, and maternal age correlation of genetically-diagnosed ploidy abnormalities. A targeted NGS-based approach that simultaneously analyzes copy number and genotyping data provides a comprehensive ploidy status assessment and helps address numerous basic and clinical research questions.

Study design, size, duration: Retrospective study including 96,660 trophectoderm biopsies analyzed between 2020 and 2022 using a targetedNGS-based PGT platform. A total of 1,063 embryos carrying haploidy or triploidy were used to investigate maternal age correlation, and parental/meiotic origin of the anomaly. Of these, 57 embryos were from concomitant PGT-M (PGT for monogenic disorders) cycles where also parental DNA was available. These trios (embryo-parents) were used to independently estimate parental/meiotic contribution to the ploidy abnormality and genome-wide recombination events.

Participants/materials, setting, methods: Targeted-NGS's accuracy in genotyping and copy number (CN) detection were previously validated on triploid cell lines and multifocal blastocyst biopsies with known ploidy status derived from abnormally fertilized oocytes. Parental and meiotic origins were estimated using two independent approaches. First, they were inferred using sex chromosomes CN from 1,063 embryos with altered ploidy status. Secondly, they were directly calculated using genotyping data from 57 trios (embryo and parents) from PGT-M cycles.

Main results and the role of chance: The prevalence of ploidy abnormalities in 2PN-derived embryos was 1.1% (n = 1,063/96,660), with triploids accounting for 83.0% (n = 882/1,063) and haploids for 17.0% (n = 181/1,063). Remarkably, the incidence of ploidy anomalies is positively correlated with maternal age (OR = 1.046 per year; $p < 0.001$). Triploidy showed strong correlation with age (OR = 1.059 per year; $p < 0.001$), while haploidy did not (OR = 0.96 per year; $p = 0.1$). Based on sex chromosomes CN analysis, the extra haploid set of triploid embryos was almost completely of maternal origin (94.6%; 95%CI:93.0-96.1), with male errors accounting for only 5.4% (95%CI:4.0-7.1). On the other hand, haploid embryos were the result of paternal errors in 97.8% of cases (95%CI:94.4-99.4), with the missing haploid set being of maternal origin in the remaining 2.2% (95%CI:0.6-5.6). In terms of triploidy's meiotic origin, two-thirds of the errors occurred during MII (95%CI:63.4-69.8), while one-third occurred during MI (95%CI:30.2-36.5). An independent method using genotyping data of 57 trios confirmed the predominance of paternal error in haploidy (n = 12/14) and the exclusively maternal origin of all embryonic triploidies (n = 43/43). The extra haploid set resulted from an error during MI in 27.9% (n = 12/43) and during MII in 72.1% (n = 31/43) of cases. Interestingly, 16.3% of triploids (n = 7/43) showed no genome-wide recombination events.

Limitations, reasons for caution: Despite the uniquely large sample size, the inference based on sex chromosomes CN suffers the limitations of the modeling assumptions (independence between parental and meiotic errors), which require further validation. Due to the low prevalence of paternal errors, clinical correlation with male factor could not be investigated with sufficient power.

Wider implications of the findings: Thanks to the exceedingly high sample size, this is the first study to reveal an increased risk of triploid conception with advancing female age (76% higher at age 40 than at age 30), providing meaningful insights for patients counseling. Importantly, the meiotic origin of ploidy anomalies in embryos were unveiled.

Study question: What is the diagnostic yield of custom designed gene panel for patients with premature ovarian insufficiency (POI)?

Summary answer: The diagnostic yield of our POI gene panel (POIGP) is 7.3%

What is known already: POI is a specific female syndrome with a high clinical and genetic heterogeneity. It is characterized by a premature exhaustion of the ovarian function and infertility and affects approximately 1% of women. POI can be related to genetic factors which include chromosomal abnormalities, FMR1 premutation and rare variants in numerous genes. The advent of high throughput sequencing methods has led to the identification of an increasing number of variants implicated in the development of POI over the last decades. However, POI etiologies still remain undetermined in the majority of cases.

Study design, size, duration: An observational analytic cohort study of 150 patients presenting idiopathic POI (normal karyotype, absence of FMR1 premutation, absence of adrenal and/or ovarian antibodies) recruited prospectively at three Belgian academic and university hospitals between 2016 and 2021.

Participants/materials, setting, methods: Patients were included if they experienced POI, as defined by ESHRE guidelines on POI (2016). POI genes included in the panel were selected from PubMed using different key words mainly premature ovarian insufficiency, gonadal dysgenesis, hypergonadotropic hypogonadism, ovarian failure and genetics. The panel included 156 genes, variants were filtered based on allele frequency (≤1%) in latest available population databases and classified according to ACMG/AMP (American College of Medical Genetics/Association for Molecular Pathology) guidelines 2015.

Main results and the role of chance: Our analysis revealed a potential causative variant for 11 patients in the following genes: MEIOB, BMP4, CFTR, FANCA, FSHR, FANCG, MLH1, MRPS22 and STARD9. This means that the diagnostic yield of our POI gene panel (POIGP) is 7.3%.

Patients were mainly Caucasian (63%), North African (17%) and sub-Saharan African (13%). They presented primary amenorrhea in 14.7% of cases. Consanguinity and/or a family history of POI or early menopause in 28% of cases. Mean patient's age (years) at POI diagnosis was 28.9 ± 8.5 (mean ± SD). The overall mean coverage was 229X, and more than 95% of the target exome was represented with more than 30-fold coverage.

Limitations, reasons for caution: The present study was limited to monogenic etiologies of POI, potential oligogenic causes have not been searched. Functional studies and/or family segregation were not performed for the identified variants.

Wider implications of the findings: Our findings show the importance of targeted next generation sequencing in clinical practice and highlight the limit of our current genetic knowledge in the field of POI. A regular update of genes included in POIGP will improve its diagnostic yield.

Trial registration number: P2016/196/CCB B406201628264

O-304 Whole-exome sequencing in women with reproductive failure is a potentially useful diagnostic test in clinical practice

T. Wu[1], X. Hu[1], M. Mo[1], S. Xu[1], H. Zhang[1], Q. Geng[1], Y. Zeng[1]

[1]*Shenzhen Zhongshan Urology Hospital, Shenzhen Key Laboratory of Reproductive Immunology for Peri-implantation- Shenzhen Zhongshan Institute for Reproduction and Genetics, Shenzhen, China*

Study question: Could whole-exome sequencing (WES) be useful in clinical practice for primary infertile female involving oocyte or embryo defects and unexplained recurrent miscarriage (RM) patients?

Summary answer: Identifying key genes involved in oocyte and embryo development helps explain approximately 17% cases of reproductive failure. WES results will help optimize clinical therapeutic treatment.

What is known already: Dozens of genes have been reported to be the genetic causes of human infertility. Variants in these genes have specific effects on certain processes of human early reproduction and result in a spectrum of phenotypes, such as oocyte maturation arrest, fertilization defects, cleavage failure, early embryonic lethality, and recurrent miscarriage.

Study design, size, duration: This retrospective cohort study was conducted from July 2020 to August 2022. A total of 129 affected females were enrolled. Most of them were primary infertile women who suffered repeated failure of *in vitro* fertilization (≥2 cycles) due to abnormal development of oocytes or embryos (PI group, n = 125). Our cohort also comprised a small number of unexplained RM subjects without offspring (RM group, n = 4). All patients and their spouses had normal karyotype.

Participants/materials, setting, methods: The peripheral blood samples from all the participants and all of their available family members were obtained for DNA extraction. Genomic DNA samples from the probands were subjected to WES to identify candidate variants. Subsequently, the variants were validated by Sanger sequencing or qPCR. Familial co-segregation analyses were then carried out within the family members. The relationship between phenotype and genotype by clinical tests and the clinical records of the patients was studied.

Main results and the role of chance: Firstly, variants that are potentially relevant to the phenotypes of female infertility were identified in 17.05% of cases (n = 22), including *TUBB8* in 14 cases, *PATL2* in 2 cases, *ZP2*, *ZP3*, *PANX1*, *TLE6*, *NLRP2* and *NLRP7* in 1 case for each. A breakdown by phenotype revealed that we identified variants in 16.00% (n = 20) of PI group and 50% (n = 2) of RM group. Secondly, 16 *TUBB8* variants were identified in 14 cases, of which 8 were novel, 3 were previously reported, and 5 were novel amino acid change occurring at the same position as another previously reported change. We found 3 *TUBB8* variants (p.C211R, p.T232I, p.A342T) in 3 embryonic arrest families and 1 *TUBB8* mutation (p.A102V) in a RM family, which were maternally inherited. Thirdly, 75 patients in PI group without phenotypic variant underwent ≥1 cycles of ovulation and/or frozen embryo transfer after WES, and 49.33% had achieved clinical pregnancy (n = 37).

Limitations, reasons for caution: The genomic DNA of parents were not available in all these 22 families, so we cannot determine whether the variant is *de novo* or inherited in some cases. Additionally, further functional studies should be performed to prove that these novel mutations affect protein function.

Wider implications of the findings: The present study expands the kinds of variants and phenotypic spectrum of gene mutations with regard to female reproductive failure. Genetic tests for causative genes involved in oocyte and embryo defects were recommended for primary infertile patients who suffered from these conditions and for unexplained RM patients.

Study question: Identify the genetic cause of a cohort of patients with unexplained Diminished ovarian reserve (DOR) by next-generation sequencing and compare with pregnancy outcome.

Summary answer: A high-yield positive genetic diagnosis was obtained: 27% of cases. Defects of genes involved in DNA repair/meiosis appeared to have an unfavorable prognosis.

What is known already: Ten percent of women undergoing Medically Assisted Procreation-MAP have a DOR defined by an AMH level <1.2 and an antral follicle count (AFC) <5. However, most causes of DOR are unknown. There is no known criteria of success in MAP. Primary ovarian insufficiency (POI) corresponds to a complete cessation of ovarian function in 1-4% of women under 40 years. We have very recently shown in a large cohort of POI that a custom-made target next-generation sequencing (NGS) POI panel allowed a genetic diagnosis in 30% of unexplained POI and leads to personalized medicine (Heddar et al., EBioMedicine. 2022 doi: 10.1016/j.ebiom.2022.104246).

Study design, size, duration: Prospective genetic study of a cohort of 100 patients with undergoing MAP using a custom-made NGS-POI panel comprising 88 validated POI-causing genes. These patients were for 77% European, 20% North African and 3% Asian. The classification of the variants detected were based on the American College of Medical Genetic criteria 2015. Only

pathogenic and likely pathogenic variants were used for diagnosis. Candidate gene studies were performed in negative patients.

Participants/materials, setting, methods: One hundred patients aged 16-35 with DOR, normal karyotype and FMR1 gene, were studied with the NGS POI panel. The segregation of the variants in the available families was performed by Sanger sequencing. Cytogenetic studies of chromosomal fragility was performed if necessary. The outcome of the pregnancy (spontaneous or induced) was recorded. A correlation between the result of the genetic study and the outcome of the pregnancy has been performed.

Main results and the role of chance: One family included two sisters, one with POI and the other with DOR, highlighting the proximity of the two syndromes. A high positive genetic yield was found: 27% of cases. Genes were involved 1) in follicular growth and gonadal development (*SOX8, AR, NOBOX, BMPR1A, BMPR1B, GNAS*) (35%) 2) DNA repair (*BNC1, ERCC6, BRCA1, ATM*) (31%) 3) metabolism and mitochondrial functions (*POLG, STAR*) (12%), 4) cellular aging (24%), in particular the *LMNA* gene.

In a patient with isolated DOR, we identified for the first time, bi-allelic truncating variants of *BRCA1*, a major breast/ovarian cancer susceptibility gene. Cytogenetic studies revealed increased chromosomal breaks with radial figures typical of Fanconi Anemia (FA). However there was no sign of FA or cancer in the patient and family. This observation is reminiscent of the family with isolated POI and biallelic mutations of *BRCA2* (Heddar et al, J Med Genet 2021; DOI: 10.1136/jmedgenet-2019-106672).

Among the 27 patients with an established genetic diagnosis, six were able to obtain a pregnancy. However, no pregnancies were achieved in the DNA repair gene suggesting an unfavorable prognosis for this gene family. On the other hand, patients with mutations of other gene families seem to have a better prognosis of fertility.

Limitations, reasons for caution: The size of the cohort should be implemented to confirm these results. The issues of pregnancy are not available for the whole cohort.

Wider implications of the findings: This is the first genetic study of a cohort of DOR and the first implication of *BRCA1* in isolated DOR. It shows i) the need for genetic studies of DOR ii) the genetic link between POI and DOR iii) NGS study could give information on the fertility prognosis of DOR.

O-306 Genome-wide association meta-analysis supports the association between MUC1 and ectopic pregnancy

N. Pujol Gualdo[1], R. Mägi[1], T. Laisk[1]

[1]*Estonian Genome Centre- Institute of Genomics, University of Tartu, Tartu, Estonia*

Study question: Can we identify genetic variants associated with ectopic pregnancy by undertaking the first genome-wide association study leveraging two large-scale biobank initiatives?

Summary answer: We identified two novel genome-wide significant associations with ectopic pregnancy, highlighting MUC1 as the most plausible affected gene.

What is known already: Ectopic pregnancy is an important cause of maternal morbidity and mortality worldwide. Despite being a common early pregnancy complication, the genetic predisposition to this condition remains understudied and no large scale genetic studies have been performed so far.

Study design, size, duration: A GWAS meta-analysis including 7,070 women with ectopic pregnancy and 248,810 controls from Estonian Biobank and the FinnGen study. Several post-GWAS analysis were conducted to characterise the genetic signals, as well as to analyse the genetic and phenotypic relationships with the condition.

Participants/materials, setting, methods: We identified ectopic pregnancy cases from national registers by ICD codes (ICD-10 O00), and all remaining women were considered controls.

Main results and the role of chance: We identified two genome-wide significant loci on chromosomes 1 (rs4971091, p = 5.32x10-9) and 10 (rs11598956, p = 2.41x10-8). Follow-up analyses propose MUC1, an epithelial glycoprotein with an important role in barrier function, as the most likely candidate for the association on chromosome 1. We also characterise the phenotypic and genetic correlations with other phenotypes, identifying a genetic correlation with smoking and diseases of the (genito)urinary and gastrointestinal system, and phenotypic correlations with various reproductive health diagnoses, reflecting the previously known epidemiological associations.

Limitations, reasons for caution: The main limitation is that the findings apply to European-based ancestry populations and we only captured maternal genomes.

Wider implications of the findings: This study encourages the use of large scale genetic datasets to unravel genetic factors linked to ectopic pregnancy, which is difficult to study in experimental settings. Increased sample size might bring additional genetic factors associating with ectopic pregnancy and inform its heritability.

P-001 ClpX is required in maintaining mitochondrial functions during meiosis and spermatogenesis

C. Guo[1], Y. Xiao[1], J. Gu[1], R. Hua[1], Z. Hai[1], J. Su[1], T. Wang[1]

[1]*The University of Hong Kong-Shenzhen Hospital, Reproductive medical center, Shenzhen, China*

Study question: What is the role of ClpX in spermatogonia differentiation and spermatogenesis?

Summary answer: ClpX is required to maintain normal mitochondrial functions in spermatocytes, deficiency of ClpX resulted in meiosisarrest and diruption of spermatogenesis in mice.

What is known already: ClpX is mitochondria-specific quality control protease, it maintains proteostasis via degrading misfolded or damagedproteins in mitochondrial matrix. ClpX is a AAA+ protease that uses the energy of ATP binding and hydrolysis to degradeunfolded or misfolded proteins. ClpX is reported working as a complex with ClpP, the complex consists of a hexamer ofClpX and a tetradecamer of ClpP. ClpX recognizes the protein substrates via binding with their unstructured peptidesequences, termed as degradation tags or recognition signals. The fragments of the cleaved polypeptides can then exitthe chamber and be further degraded.

Study design, size, duration: Study design: we generated a germ cell specific ClpX knockout mice line and evaluated size, weight, inner structure oftestis tissue. We also applied biochemical techniques and high-throughput sequencing techniques to investigate themechanism of ClpX in regulating spermatogenesis.

Size: more than 50 mice were used in this study, including the control mice.

Duration: 2 years

Participants/materials, setting, methods: Participants/materials: we generated a ClpX conditional knockout (cKO) mice line by CRISPR-gene editing and Cre-LoxP system, which specifically knockout ClpX in the germ cells of male mice.

Setting: the siblings of ClpX WT mice and ClpX cKO mice were compared in various of experiments.

Mehods: we performed morphology comparement to check the weight and size of tetes in the control and ClpX cKOmice, and applied immunofluorescence, western blot, histological study, high-throughput sequencing andpharmocological treatment.

Main results and the role of chance: We found ClpX deficiency reduced mitochondrial functions and quantity in spermatocytes, affected energy supply duringmeiosis and attenuated zygotene-pachytene transformation of the male

germ cells. The affected spermatocytesexhibited disorder of chromosome synapsis and cross-over events. Their telomeres failed to attach to the nuclearenvelop, which was associated with failure of α-tubulin formation in the ClpX deficient spermatocytes. The dysregulatedspermatocytes finally underwent apoptosis resulting in decreased testicular size and vacuolar structures within theseminiferous tubules. Both transcriptome analysis and m6A-methylation sequencing analysis highlighted dysregulationof metabolic pathways including the mTOR signaling in the isolated spermatocytes. We confirmed over-activation of themTORC1 pathway with increased expression of phosphorylated S6 and 4EBP after deletion of ClpX in spermatocytes.Long-term inhibition of the mTORC1 signaling via rapamycin treatment in vivo partially rescue spermatogenesis in theseminiferous tubules with much less apoptotic germ cells and formation of late stage of meiotic germ cells, such asround spermatids and elongated spermatozoon. The data reveal the novel roles of ClpX in regulating meiosis andspermatogenesis.

Limitations, reasons for caution: This study is based on animal experiments, thus, these results only indicated the important roles of ClpX in micespermatogenesis rather than human beings. Clinical data has not yet found a Clpx gene mutation in reproductivedisease.

Wider implications of the findings: Clinical report has already found the mutation in ClpP can induce autosomal recessive Perrault syndrome, while themutation of ClpX has not been reported yet from clinical data. Our resutls demonstrated severe effect onspermatogenesis after knockingout of ClpX, this might give some insights to the clinic.

Study question: In human testicular cells, how are SARS-CoV-2 receptors and their priming proteases for the viral spike (S) protein distributed spatially?

Summary answer: Human testicular tissue expressed both the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) receptors and proteases investigated, key factors for cellular susceptibility to SARS-CoV-2 entry/infection.

What is known already: Male reproductive function is altered on numerous levels by SARS-CoV-2 and coronavirus disease. Angiotensin-converting enzyme 2 (ACE2) is the main SARS-CoV-2 host membrane receptor but requires transmembrane protease serine 2 (TMPRSS2) for S protein priming (activation by proteolysis). Other proteases, like cathepsin L (CTSL), might nevertheless contribute to SARS-CoV-2 entrance. This mostly happens in cells with low or nonexistent ACE2 expression, which calls for alternative receptors like cluster of differentiation 147 (CD147). Although co-expression of receptors and proteases is essential for successful SARS-CoV-2 infection, it is still unknown how viral receptors and accompanying proteases are distributed geographically in testicular cells.

Study design, size, duration: To overcome this restriction, we focused on using immunohistochemistry to map the spatial distribution of the SARS-CoV-2 receptors ACE2 and CD147, as well as their priming proteases for the viral spike (S) protein, TMPRSS2 and CTSL, which are necessary for viral fusion with host cells, in human testicular tissue.

Participants/materials, setting, methods: Laboratory experiments were executed under the Joint Ethics Committee of the Hospital and University (approval number 2020-094 (077-DEFI-078-CE)). Human testicular tissues were obtained from cases presenting Sertoli cell syndrome, maturation arrest, and hypospermatogenesis at the Hospital Pathology department, with five patients per pathology. Formalin-fixed paraffin-embedded tissue sections 4 µm were incubated with anti-antibodies ACE2 (orb638860, 1:100 and 1:150, Byorbit), TMPRSS2 (ab109131, 1:1000, Abcam), CD147 (MA5-29060, 1:2500, Invitrogen) and CTSL (MA5-32602, 1:100, Invitrogen).

Main results and the role of chance: The present study did not intend to study the virus entry proteins in different testicular pathologies. As spermatogenesis is a complex process involving many intricately linked cells, we selected these syndromes specifically to identify individual cells more clearly, Sertoli cells in Sertoli cell-only syndrome cases, spermatocytes in maturation arrest cases and spermatids in hypospermatogenesis cases. The hypospermatogenesis group consisted of cases whose azoospermia was due to duct obstruction, showing conserved spermatogenesis. Interstitial cells, including endothelium, Leydig and myoid peritubular cells, and the seminiferous epithelium (Sertoli cells, spermatogonia, spermatocytes, and spermatids), were discovered to contain ACE2 and TMPRSS2, demonstrating co-expression of both receptor and protease in all testicular cells. All cell types, with the exception of endothelium and peritubular cells, showed the presence of CD147, whereas CTSL was only found in Leydig, peritubular, and Sertoli cells. As a result, only Leydig and Sertoli cells co-expressed CD147 and CTSL. The findings of proteomic databases indicating testicular cells have SARS-CoV-2 receptors and proteases are supported by our discoveries, demonstrating that testicular cells may be directly infected and injured, halting spermatogenesis and acting as viral vectors for the SARS-CoV-2.

Limitations, reasons for caution: Our results support viral tropism for human testicular cells and raise the possibility of testicular manifestations, although this does not necessarily mean that the virus infects testicular cells directly and further studies are needed to discern SARS-CoV-2 infection and transmission targeting alternative receptors and to identify the underlying mechanisms.

Wider implications of the findings: Male reproductive system susceptibility to viral infections has long been demonstrated. To prevent infection by allowing the virus to attach to germ cells, impair sperm production, and increase the risk of meiotic errors and viruses spreading through sperm, our study emphasizes the importance of safe practices in the wider community.

Trial registration number: not applicable

Abstract citation ID: dead093.373
P-003 Obstructive azoospermia; MESA should be employed as the method for sperm retrieval, not TESE

H. Hibi[1], M. Sonohara[2], M. Sugie[1], N. Fukunaga[3], Y. Asada[4]

[1]Kyoritsu General Hospital, Urology, Nagoya, Japan
[2]Asada Ladies Clinic, Gynecology, Nagoya, Japan
[3]Asada Institute for Reproductive Medicine, Embryology, Nagoya, Japan
[4]Asada Institute for Reproductive Medicine, Gynecology, Nagoya, Japan

Study question: TESE is widely used for obstructive azoospermia (OA) as a surgical method for sperm retrieval, but is it benefiting the patient?

Summary answer: Since MESA-ICSI has a very good fertilization rate, clinical pregnancy rate and delivery rate, MESA should be employed for the OA subjects, not TESE.

What is known already: TESE and micro-TESE are technically simple, and widely used as a sperm retrieval surgery because they do not require microsurgical skills. Some review articles have shown no significant differences in the rates of cleavage, good-quality embryos, implantation, clinical pregnancy

between ICSI with epididymal sperm or testicular sperm. Clinical usefulness of MESA is still controversial according to previous reports.

Study design, size, duration: We studied 110 patients diagnosed with OA and treated with MESA at the Asada Ladies Clinic between April 2004 and December 2021.

Participants/materials, setting, methods: The MESA was performed using a micropipette with a micropuncture technique under operative microscope. When no sperm were present or motility was not observed, additional punctures to the epididymal tubule were performed. Aspirated samples were transferred into modified human tubal fluid and sent to the in vitro fertilization (IVF) laboratory for cryopreservation.

Main results and the role of chance: Motile sperm were recovered in all cases (110 cases). Of these, ICSI using frozen thawed sperm was performed in 101 cases. The rate of normal fertilization rate was 76%. Of the 399 embryo transfer (ET) cycles, 168 had a clinical pregnancy (41% per ET). Of the 101 patients who underwent ART, 94 (93% per case) had clinical pregnancies resulting in 90 (89.1%) deliveries. It should be emphasized that since MESA does not involve incision of the testes, there are fewer postoperative peritoneal irritation symptoms and no concerns about postoperative testicular atrophy or low testosterone levels. Some review articles showed no significant differences in the rates of cleavage, good-quality embryo, implantation, clinical pregnancy between ICSI with epididymal sperm or testicular sperm. Although clinical usefulness of MESA is still controversial, if the ART results of MESA-ICSI and TESE-ICSI are the same, MESA should be performed as it is less invasive on the patient and reduces the burden on the embryologist who have to process the TESE tissue.

Limitations, reasons for caution: Some authors have reported that since MESA specimens contain DNA fragmentated sperm when compared with specimen of TESE, subsequent ICSI results in poorer fertilization and pregnancy rates. We did not evaluate sperm DNA fragmentation.

Wider implications of the findings: A large quantity of uncontaminated sperm can be retrieved using MESA which is less invasive for the patient, and there is no need for special processing before cryopreservation. Additionally, it can reduce the laboratory workload.

Trial registration number: not applicable

Abstract citation ID: dead093.374
P-004 Sperm concentration of less than 1 million/ml in Y microdeletion patients may affect ICSI clinical outcomes: a propensity score matching analysis

H. Zhang[1]

[1]*School of Basic Medical Science- Central South University, Institute of Reproductive and Stem Cell Engineering-, Changsha, China*

Study question: To investigate which semen parameter in AZFc microdeletion patients affect the intracytoplasmic sperm injection (ICSI) clinical outcomes.

Summary answer: AZF-microdeletion caused oligospermia affected the ICSI clinical outcome when the sperm concentration is less than $1x10^{6/ml}$.

What is known already: To reduce the impact of female factors on clinical outcomes, this study employed a propensity score matching analysis to retrospectively analyze the laboratory and clinical pregnancy results of patients with AZFc deletion who underwent ICSI.

Study design, size, duration: A propensity score matching analysis in a retrospective ICSI cohort of 99 AZFc microdeletion patients and 198 oligospermia patients without AZFc microdeletion.

Participants/materials, setting, methods:

Patients/Animals: oligospermia patients with or without AZFc microdeletion undergoing ICSI.

Intervention: ICSI for couples attempting conception.

Main Outcome Measures: Outcomes included normal fertilization rate, high-quality embryo rate on Day 3, clinical pregnancy rate, abortion rate, and live birth rate.

Main results and the role of chance: Patients with AZFc microdeletion had a lower normal fertilization rate (69.55%) and Day-3 high-quality embryo rate (50.73%) than the control group (77.17% and 58.44% respectively, $p = 0.000$). There was no significant difference between the two groups in the clinical pregnancy rate (67.21% vs. 68.16%, $p > 0.05$), miscarriage rate (13.41% vs. 12.54%, $p > 0.05$), and live birth rate (58.20% vs. 59.18%, $p > 0.05$). Subgroup analysis showed that the fertilization rate, high-quality embryo rate, clinical pregnancy rate, and live birth rate were comparable between the AZFc-microdeletion group and the control groups when the sperm concentration was no less than $10^{6/ml}$. Interestingly, when the sperm concentration was below $1x10^{6/ml}$, the fertilization rate (65.60% vs. 73.79%, $p = 0.001$) and high-quality embryo rate (47.74% vs. 58.48%, $p = 0.001$) in the AZFc-microdeletion group were significantly lower than those in the control group. Furthermore, the clinical pregnancy rate and live birth rate were lower, while the miscarriage rate was higher in the AZFc-microdeletion group; however, the statistical difference is not significant.

Limitations, reasons for caution: the retrospective study was limited, and the cases of obtaining testicular sperm by microsurgery were not included, so the results may be biased, and prospective studies with larger sample size need to be designed for further confirmation.

Wider implications of the findings: We recommend screening for AZF in Chinese male infertile population when sperm concentration is below $5X10^{6/ml}$.The male physician should advise the patient to undergo genetic counseling before pregnancy assistance, and choose whether to choose PGT assisted pregnancy according to the patient's wishes.

Trial registration number: not applicable

Abstract citation ID: dead093.375
P-005 Association between aging and semen parameters: a retrospective study on over 2,500 men

C. Castellini[1], **D. Tienforti**[1], **F. Di Giulio**[1], **L. Spagnolo**[1], **F. D'Alessandro**[1], **F. Antolini**[1], **G. Cordeschi**[1], **A. Barbonetti**[1]

[1]*University of L'Aquila, Andrology Unit- Department of Life- Health and Environmental Sciences, L'Aquila, Italy*

Study question: Is there an association between advancing male age and worsening seminal parameters (If so, is it possible to define an age-threshold for semen quality decline)?

Summary answer: Only sperm morphology and motility-related parameters exhibited a significant negative association with age, particularly from the age of 40 years.

What is known already: While the importance of advanced maternal age on reduced fertility and higher reproductive risks is well documented, scarce and controversial are the information regarding the role of aging on male fertility potential. Indeed, growing concerns arise from the trend in the advancing average parenthood age in Western countries.

Study design, size, duration: A retrospective study was conducted in 11,307 consecutive semen samples obtained from men who attended the Andrology Unit of the University Hospital of L'Aquila, during the period from January 1992 to January 2022 for evaluation of their fertility potential.

Participants/materials, setting, methods: Semen samples were collected by masturbation into sterile containers after a sexual abstinence of 2-7 days. Total sperm count (TSC) was calculated by multiplying sperm concentration and the volume of the ejaculate, motile sperm concentration (MSC) was calculated by multiplying sperm concentration and progressive motility (%), and the total motile sperm count (TMSC) was calculated by multiplying MSC and volume. Leukocytospermia was defined as $> 1x10^6$ peroxidase-positive cells/mL.

Main results and the role of chance: Three hundred and forty-nine patients with azoospermia or severe oligozoospermia ($<5x10^6$ spz/ml) were excluded. Moreover, 8,450 were excluded because they were only subjected to semen analysis without concomitant clinical evaluation. Therefore, 2,508 subjects have been included in the final analysis. Significant inverse correlations were observed between male age and semen volume (p=0.04), total (p<0.0001) and progressive sperm motility (p<0.0001), TMSC (p=0.01), total progressive motile count (p=0.008), and percentage of spermatozoa with normal morphology (p=0.001), but not with sperm concentration (p=0.8)

and TSC (p=0.2). After adjustment for abstinence time, smoking, history of genital tract infections, genital trauma, varicocele, cryptorchidism, orchiectomy, and the year the semen analysis, a significant negative association was found for total (p<0.0001) and progressive motility (p=0.0003), TSC (p=0.001), total progressive motile count (p=0.001), and normal morphology (p=0.035). The comparison of seminal parameters among age quartiles revealed that the age group above 40 years was associated with a significant reduction in total and progressive motility, total motile, and total progressive motile count, while the decline in the percentage of normal forms appeared to be earlier.

Limitations, reasons for caution: The present study did not analyze couple reproductive outcomes. Moreover, since sperm DNA fragmentation was available only for a limited number of subjects, it was not possible to assess its possible association with male aging.

Wider implications of the findings: In the light of the possible role of oxidative stress in affecting semen parameters in men aged over 40, the optimization of paternal lifestyle combined with targeted antioxidants treatments could be valuable preventive tools in the couple infertility work-up.

P-006 In men with Raised Sperm DNA Fragmentation Index, would advance Sperm Preparation techniques alter Embryo Euploidy?

S. Debnath[1], K. Chaitanya M[1], D. Rao Gedela[2]

[1]*Oasis Fertility, Embryology, Hyderabad, India*
[2]*Oasis Fertility, Clinical, Hyderabad, India*

Study question: In men with Raised Sperm DNA Fragmentation Index (DFI), Would advance sperm preparation techniques at Intra-Cytoplasmic Sperm Injection (ICSI) alter embryo euploidy status?

Summary answer: In men with raised Sperm DFI, use of advance sperm selection techniques are safe and do not appear to alter ploidy status of the embryos

What is known already: MACS (Magnetic Activated Cell Sorting), Microfluidic Sperm Sorting (MF), surgically retrieved Testicular Sperm (TESA) and Double Density Gradient sperm processing (DDG) have been shown to optimize sperm selection at ICSI for men with raised sperm DFI. Would any of these sperm selection methods alter embryo ploidy status is not proven

Study design, size, duration: This was a retrospective observational study conducted at a private fertility centre in-between years 2015 & 2022. Couples where women (<37yrs) had idiopathic Recurrent Implantation Failures (RIF) and men had raised sperm DFI (>25% DFI) and underwent Pre-Implantation Genetic Testing (PGT) were evaluated (n = 473). Based on sperm selection method the study population was divided into four groups. TESA (n = 84), MACS (n = 105), MF(n = 135), DDG (n = 148).A total of 1802 embryos were evaluated in this study.

Participants/materials, setting, methods: All women underwent Controlled Ovarian Stimulation (COS) and oocyte retrieval and male partners underwent sperm processing as per the clinics SOP. Appropriate counselling and written consents were obtained from all couples, where applicable. All oocytes subjected to ICSI, extended blastocyst culture and trophoectoderm (TE) biopsy. Post biopsy embryos were vitrified and TE tissue subjected to Next-Generation Sequencing (NGS) to assess the ploidy status. Ploidy status between various sperm selection methods was compared.

Main results and the role of chance: Euploidy rates between the study groups were as follows:

TESA (n = 311 embryos screened)- 48%
MACS (n = 445 embryos screened) – 51%
MF (n = 489 embryos screened) – 61%
DDG (n = 557 embryos screened)- 54%

Though numerically the ploidy status was highest in MF group for euploid embryos, there seems to be no statistical significance between the groups (p-value = 0.973). Different sperm selection techniques do not seem to alter embryo ploidy status.

Ejaculated sperm or Testicular sperms had similar euploidy status. Use of Testicular sperm, which is considered immature doesn't seem to increase embryo aneuploidy.

MACS, MF and DDG all seemed to have similar euploid embryos. This further warrants research to validate the role of MACS and MF as a routine intervention to optimize sperm selection and reproductive outcomes.

Limitations, reasons for caution: Retrospective design, un-equal group size and small sample size, a well-designed study is needed to further validate the findings of this study.

Wider implications of the findings: Role of advance sperm selection methods to optimize embryo implantation is yet to be proven. Data from this study showed no alarming increase in embryo aneuploidy in younger women and was comparable with published literature. Use of advance sperm selection techniques seems safe and doesn't alter embryo ploidy status.

Trial registration number: not applicable

P-007 A Four Arm Prospective Randomized Control Trial to Investigate the Role of Advance Sperm Selection Techniques for Raised Sperm DNA Fragmentation Index

K.C. Mantravadi[1], D.R. Gedela[2], M. Sambangi[1], V.J.K. Manepalli[1]

[1]*Oasis Fertility, Embryology, Hyderabad, India*
[2]*Oasis Fertility, Infertility, Hyderabad, India*

Study question: Role of Testicular Sperm Aspiration (TESA), Magnetic Activated Cell Sorting (MACS), Microfluidics & Daily ejaculation, to reduce raised Sperm DNA Fragmentation Index (SDF) & evaluate impact on outcomes?

Summary answer: Amongst the advance sperm selection methods, Microfluidic sperm sorting seems to significantly reduce the SDF and offer the best reproductive outcomes

What is known already: Raised SDF is known to affect the reproductive outcomes of a couple. There are various sperm processing methods/interventions shown to reduce the sperm DNA fragmentation, but their effectiveness to optimize reproductive outcomes is still debatabl.

Study design, size, duration: RCT approved by the Institutional Ethical Committee. IEC No.:1312/Inst/TG/2019. Couples undergoing IVF with raised SDF were randomized into four arms by computer generated randomized numbers from October 2019 to May 2022 (n = 466). Of those 373 patients recruited to, TESA (n = 129), MACS (n = 92), Microfluidics (n = 116) Daily ejaculation (n = 36) . Males with SDF > 25% & Age 25-40 yrs were included. Women>37 yrs, BMI >30 and men with Smoking, Binge alcohol, varicocele excluded.

Couples with one failed IVF were offered SDF. SDF>25%was considered raised and were included in study.

Participants/materials, setting, methods: After Oocyte Pick Up (OPU), sample processed for ICSI and was sent for post intervention SDF. TESA done as per SOP of clinic. MACS & Microfluidics done as per instruction from manufacturer. Daily ejaculate group, patient ejaculated daily for 1week prior to OPU and at OPU, fresh ejaculate processed through density gradient. Men with high SDF, after randomization were subjected to OPU, ICSI, Blastocyst Culture, Freeze all policy and Frozen Embryo Transfer with 2blastocysts

Main results and the role of chance: Primary outcome-magnitude of reduction in SDF post intervention

Secondary outcomes – Blastocyst Rate (BR), Implantation rates (IR), Live birth (LBR)Mean of SDF on Raw Semen Sample Vs Post Intervention Sample:

TESA – 44% Vs 25.75%
Microfluidics - 34.4% Vs 9.8% (p < 0.05; Significant)
MACS – 32.2% Vs 27.95%
Daily Ejaculation 39.37% Vs 19.66%

Microfluidics seem to be beneficial intervention in significantly reducing the SDF. MACS seemed to have offered the least reduction of SDF.

BR: This was comparable between all groups with no statistical significance

Reproductive Outcomes for TESA, Microfluidics, MACS & Daily ejaculation:

IR – 39.3% Vs 57.27% Vs 46.4% Vs 61% (p = 0.1)

LBR – 60% VS 65% Vs 64% Vs 61% (p = 0.41)

Miscarriage Rates and Multiple Pregnancy rates were comparable between the groups and statistically not significant.

We observe that microfluidics was the best sperm processing method as it significantly reduced the DFI and had the best reproductive outcomes. It is noninvasive and can be done easily. Even though there was no statistical significance, Daily ejaculation yielded equivocal outcomes than the other 3 groups. Considering the ease, cost effectiveness and optimal reproductive outcomes Daily Ejaculation can also be offered to patients with raised SDF. Though TESA had acceptable outcomes, considering its invasiveness adequate counselling is warranted. Outcomes for MACS were guarded and be suggested with caution.

Limitations, reasons for caution: The sample size is small in the daily ejaculate arm as there were many dropouts.

The unequal size of the arms would affect the results. So, we are continuing the randomization and intend to look into the results with equal size of the arms in the future

Wider implications of the findings: Published literature has shown raised SDF to be detrimental to reproductive outcomes. There is an urgent need for an efficient intervention which is safe, economical, easy to use and offers the best reproductive outcomes. Daily ejaculation, a traditional concept which is cost effective needs due consideration over other techniques.

P-008 Acetate ameliorates doxorubicin-induced testicular toxicity by modulating Nrf2/NFkB pathway and apoptotic signaling

R. Akhigbe[1], D. Adeyemi[2], M. Hamed[3], T. Akhigbe[4]

[1]*Ladoke Akintola University of Technology- Ogbomoso- Oyo State- Nigeria, Physiology, Ogbomoso, Nigeria*
[2]*Osun State University- Osogbo- Osun State- Nigeria., Department of Physiology, Osogbo, Nigeria*
[3]*Afe Babalola University- Ado-Ekiti- Ekiti State- Nigeria, Department of Medical Laboratory Science, Ado Ekiti, Nigeria*
[4]*Osun State University- Osogbo- Osun State- Nigeria., Department of Physiology, Ejigbo, Nigeria*

Study question: Will acetate treatment ameliorate doxorubicin-induced testicular toxicity when used concomitantly?

Summary answer: Acetate ameliorated doxorubicin-induced testicular toxicity by modulating Nrf2/NFkB and apoptotic signaling.

What is known already: Doxorubicin is an antineoplastic agent that is effective in the management of several forms of cancers. However, a major limitation of this drug is its testicular toxicity. Studies have revealed that doxorubicin impairs male fertility by inducing testicular injury via downregulation of Nrf2 and upregulation of NFkB and apoptotic signaling. On the other hand, acetate upregulates Nrf2 and downregulates NFkB and apoptotic signaling. Yet, no study has reported the impact of acetate on doxorubicin-induced testicular toxicity.

Study design, size, duration: This is a prospective experimental study using animal model. Thirty two sexually mature litter-mate male Wistar rats of comparable weight were used for the study. The study lasted 8 weeks.

Participants/materials, setting, methods: Animals were acclimatized for two weeks, then randomized into four groups (n = 8). The control rats received 0.5mL of distilled water as vehicle *p.o* for 14 days, acetate-treated rats received 200 mg/kg/day of acetate *p.o* for 14 days, doxorubicin-treated rats received 7 mg/kg of doxorubicin *i.p* on day 8, while acetate + doxorubicin-treated rats received treatment as acetate-treated and doxorubicin-treated. The doses of drugs used were the Human Equivalent doses for rats.

Main results and the role of chance: Acetate ameliorated doxorubicin-induced rise in testicular activities of gamma glutamyl transferase, lactate dehydrogenase activity, and lactate levels. Also, acetate ameliorated doxorubicin-induced decline in the activities of testicular superoxide dismutase and catalase, and glutathione and Nrf2 concentrations. Acetate also alleviated doxorubicin-induced rise in testicular MPO activities, malondialdehyde, TNF-α, IL-1β, and NF-*k*B levels. More so, acetate ameliorated doxorubicin-induced reduction in spermatogenic indices and sperm quality, circulatory levels of FSH, LH, and testosterone, and testicular concentrations of 3β-HSD, 17β-HSD, and testosterone. These events were associated with dampening of doxorubicin-induced upregulation of Bax, caspase 3 and caspase 9 activities and doxorubicin-induced downregulation of BCl-2 by acetate.

Limitations, reasons for caution: This study was conducted in a rat model; therefore the results of the present study should be extrapolated to human with caution. Clinical trials are recommended to validate these findings.

Wider implications of the findings: The present study demonstrated the ameliorative effect of acetate treatment on doxorubicin-induced testicular toxicity. These findings provide substantive evidence of the possible protective role of acetate in doxorubicin-induced testicular toxicity.

P-009 Impact of organophosphate pesticide exposure on human semen quality and circulating testosterone: a systematic review and meta-analysis

T. Akhigbe[1], A. Adeogun[2], M. Hamed[3], R. Akhigbe[4]

[1]*Osun State University, PLANT BREEDING AND GENETICS, OSOGBO, Nigeria*
[2]*Ladoke Akintola University of Technology- Ogbomoso- Oyo State- Nigeria, Department of Physiology-, Ogbomoso, Nigeria*
[3]*Afe Babalola University- Ado-Ekiti- Ekiti State, Department of Medical Laboratory Science, Ado Ekiti, Nigeria*
[4]*Ladoke Akintola University of Technology- Ogbomoso- Oyo State- Nigeria, Department of Physiology, Ogbomoso, Nigeria*

Study question: Does exposure to organophosphate pesticides (OP pesticides) alter human semen quality and circulating testosterone levels?

Summary answer: Exposure to OP pesticides reduced sperm count, concentration, total and progressive motility, and normal sperm morphology, possibly via a testosterone-independent mechanism.

What is known already: OP pesticides have been associated with a decline in semen quality, although there are still considerable arguments about the magnitude of the association. Also, human data on semen quality and male reproductive hormones in association with OP pesticide exposure is limited and inconsistent.

Study design, size, duration: This study provides a systematic review and meta-analysis of the impacts of OP pesticide on semen quality and male reproductive hormones.

Participants/materials, setting, methods: This study was conducted according to PRISMA guidelines. Following a pre-defined strategic protocol, 1, 001 studies were screened and 9 articles were identified as eligible for this study. Two of the studies were from China, and one each from Japan, Peru, France, Mexico, Malaysia, Venezuela, and Iran. Two of the studies did not specify the types of OP pesticide used, while the remaining 7 did.

Main results and the role of chance: A total of 766 male subjects (349 exposed to OP pesticide and 417 unexposed controls) were included in the meta-analysis. There was no significant difference in the ejaculate volume, seminal fluid volume, sperm multiple anomaly index, and leukocytes levels of the OP-exposed subjects compared to the control. In addition, OP pesticide exposure did not significantly affect serum concentrations of FSH, LH, and testosterone in subjects who were exposed to OP pesticide compared to their unexposed counterparts. However, we found a significant reduction in the sperm count, sperm concentration, progressive sperm motility, total sperm motility, and normal sperm morphology of OP pesticide-exposed subjects compared to the unexposed subjects. However, after subtype and sensitivity analyses, exposure to OP pesticide did not significantly reduce sperm count. In addition, after sensitivity analysis, OP pesticide exposure did not significantly alter progressive sperm motility.

Limitations, reasons for caution: The non-inclusion of non-English publications in this study and the scarcity of well-designed studies to be included

might have limited the pooled sample size and inadequately explored the impacts of OP. Also, the included studies are from a few countries, which may not necessarily be a good global representative.

Wider implications of the findings: The present comprehensive meta-analysis clearly demonstrates that exposure to OP pesticide causes reduced sperm count, concentration, total and progressive motility, and normal sperm morphology, possibly via a testosterone-independent mechanism. These findings strengthen existing evidence in the literature on the negative impacts OP pesticide exposure on semen quality.

P-010 The impact of COVID-19 Vaccination on Sperm Parameters in Indian Men: A Comparative Study

G. Mittal[1], K.C. Mantravadi[2], D. Rao Gadela[2]

[1]*Oasis Fertility, Embryology, Mangalore, India*
[2]*Oasis Fertility, Embryology, Hyderabad, India*

Study question: To analyse the effect of COVID-19 vaccines on sperm parameters in Indian men seeking infertility treatment.

Summary answer: COVID-19 vaccination did not impact the sperm parameters of Indian men undergoing infertility treatment in this study.

What is known already: The COVID-19 pandemic triggered an expedited response from the scientific community to develop preventive vaccine programs against the deadly SARS-CoV-2 virus. Although COVID-19 is predominantly a respiratory system illness, initial reports suggested that it could have a short-term negative impact on the sperm parameters of the males affected by the disease too. Misinformation led to unfounded concerns about the potential consequences of the vaccines on male fertility, causing a great deal of initial vaccine hesitancy. To address these concerns, we compared the sperm parameters in men before and after COVID vaccination available in India at the time of this study.

Study design, size, duration: It was a multi-centre, prospective, observational study of 960 male participants conducted at our fertility clinics between June 2021 to December 2022.

The study participants were matched for age and had no known risk factors. We excluded 267 participants from this study since they did not meet the inclusion criteria, bringing our total study population down to 693.

Participants/materials, setting, methods: The study participants provided two semen samples for analysis before and after receiving any of the COVID-19 vaccines available in India at the time of this study. A trained embryologist analysed the pre-vaccination and post-vaccination sperm concentration and motility of these males, following the 6th Edition of WHO Manual for Semen Analysis. GraphPad Prism 9 was used for statistical analysis of the data & $p \leq 0.05$ was considered statistically significant.

Main results and the role of chance: The study enrolled 693 people, with 96.5% receiving at least one dose and 90.35% receiving two or more. The most common vaccines used among the group were Indian made-Covishield and Covaxin, received by **71.8**% & 24.3% of the participants, respectively.

In the group of participants who had tested positive for COVID (n = 259), the sperm concentration increased by 3.29 million/ml and the total motility increased by 3.24% post-vaccination. However, these changes were not statistically significant ($p = 0.140$ and $p = 0.099$, respectively).

In the group of participants who had not tested positive for COVID (n = 424), we observed a similar increase in sperm concentration and total motility post-vaccination. The sperm concentration increased by 1.52 million/ml and the total motility increased by 0.85%. However, these changes were also not statistically significant ($p = 0.580$ and $p = 0.404$, respectively). Subgroup analysis of different vaccines did not reveal any statistically significant differences either.

In conclusion, the study found that COVID-19 vaccination, including the type of vaccine used, did not significantly impact sperm parameters in men.

Limitations, reasons for caution: Supply chain disruptions in the COVID vaccination program meant we could not match the duration between the pre-vaccination and the post-vaccination semen analyses in this study. Additionally, the findings are specific to our study population and may not be generalizable to other populations or settings.

Wider implications of the findings: This study found that COVID-19 vaccination did not affect the chances of Indian men at fatherhood. Our work also supports the safety of Indian-made vaccines for men seeking infertility treatment, as it is one of the most extensive studies in this area.

P-011 Slight decreases in cumulative live birth rates when using frozen-thawed semen samples for ICSI with donor oocytes do not mean we should stop freezing

M. Gil Julia[1], M. Cozzolino[2], I. Hervás[3], A. Navarro-Gomezlechon[4], L. Mossetti[3], R. Pacheco-Rendón[4], R. Rivera-Egea[5], N. Garrido[4]

[1]*IVI Foundation, Andrology and Male Infertility, Valencia, Spain*
[2]*IVIRMA Rome, Gynaecology, Rome, Italy*
[3]*IVIRMA Rome, IVF laboratory, Rome, Italy*
[4]*IVI Foundation- Health Research Insitute La Fe, Andrology and Male Infertility, Valencia, Spain*
[5]*IVIRMA Valencia, Andrology laboratory, Valencia, Spain*

Study question: Does the use of autologous frozen semen samples for ICSI with donor oocytes make any difference in reproductive outcomes compared to using fresh samples?

Summary answer: Although it seems slightly detrimental in several intermediate outcomes, the advantages of using frozen samples in cycle logistics outweigh this potential decrease in results.

What is known already: Sperm freezing has become a part of day-to-day practice in infertility clinics due to its many logistic benefits. However, there is no clear consensus on the impact of freezing-thawing semen samples prior to ICSI on cycle outcomes. Moreover, most studies express results according to classical outcomes of reproductive success (i.e. pregnancy rate or live birth rate (LBR) per embryo transfer (ET)). Cumulative LBR (CLBR) are a more realistic approach to expressing the probability of achieving a livebirth when assessing the effect of a technique, since they compute the contribution of all used oocytes and embryos from the same cohort.

Study design, size, duration: Retrospective multicenter observational cohort study involving 45,120 ICSI procedures with donor oocytes (34,847 with fresh semen samples and 10,269 with frozen samples) from January 2008 to November 2021. The fresh sample group included real-world data from the clinical records of these patients and cycles from a cohort of 387,903 inseminated oocytes and 75,116 embryos transferred in 49,775 ET; whereas the frozen sample group considered 110,983 injected oocytes and 24,334 embryos replaced in 14,953 ET.

Participants/materials, setting, methods: Pregnancy rates and LBR per ET were computed and then adjusted to female and male patients' age and BMI, total progressive motile sperm, semen capacitation, transfer before or at blastocyst stage, and use of PGT, using generalized linear models to compute adjusted odds ratios (adjOR) and p-values comparing both groups. CLBR per ET, embryo replaced and used oocyte were plotted in Kaplan-Meier curves adjusted according to donors' and female patients' age in Cox regression models.

Main results and the role of chance: There were statistically significant differences between both groups in terms of biochemical, clinical and ongoing pregnancy rates per ET, and LBR per ET. After the multivariate analysis, these differences remained statistically significant with adjusted p-value <0.001. The adjOR were 1.091 (1.045-1.139), 1.133 (1.086-1.183), 1.115 (1.067-1.165) and 1.168 (1.114-1.223) respectively when considering the frozen sample group as the reference. CLBR was 57.73% (57.05-58.41) after three embryos were transferred and 73.31% (72.44-74.16) after five embryos replaced in the fresh sample group, compared to the 49.65% (48.40-50.88) and 66.58% (64.92-68.16) CLBR in the frozen sample group ($p < 0.001$). The adjusted hazard ratio for this comparison was 1.146 (1.100-1.195). The CLBR in the fresh sample group was 45.74% (45.10-46.37) and 69.25% (68.46-70.02) after 10 and 14 donor oocytes were used, while the rates for the frozen sample

group were 43.87% (42.66-45.05) and 68.83% (67.17-70.40) respectively (p = 0.0002). The adjusted hazard ratio was 1.067 (1.023-1.112), with an adjusted p-value of 0.002. In the fresh sample group, 5.6% of the used oocytes resulted in the couples' first newborn (267,462 oocytes and 15,153 newborns), whereas in the frozen sample group it was the 5.2% of oocytes (77,284 oocytes and 4,040 newborns), which is consistent with the published literature.

Limitations, reasons for caution: The retrospective nature of the study subjects data to biases and inaccuracies in their annotation in clinical sources from which they were exported, although the multivariate statistical analyses aimed to control those biases. Considering only donor oocytes also reduces some of the variability since it homogenizes factors concerning oocyte quality.

Wider implications of the findings: Although the frozen samples group had slightly decreased success rates, the CLBR per used oocyte remained between around two percent lower compared to using fresh samples. Thus, the large sample size and real-world data included show that the subtly lower rates do not outweigh the logistic benefits of sample freezing.

P-012 Time, risk & motion study of an integrated artificial intelligence robotic system for semen analysis

K. Hill[1], M. Alvarez[1], F. Mora[1], D. Thomas[2], A. Tozer[3], X. Viñals Gonzalez[1]

[1]Aria Fertility, Laboratory, London, United Kingdom
[2]Mojo, Mojo, Lyon, France
[3]Aria Fertility, Clinical, London, United Kingdom

Study question: Can integration of a robotic system for semen analysis reduce operational failure modes and eliminate risk in the IVF laboratory?

Summary answer: A robotic system for semen analysis reduces operational failure modes and eliminates severe risks including those associated with reduced patient experience and increased patient stress.

What is known already: Recently, the ever-evolving field of IVF has experienced a rise in innovations to boost laboratory performance. Considering the lack of robust evidence in some of them, decisions on implementation are often based on opinion and product cost. Currently, an approach to assess risk, time and effectiveness has not been fully described. IVF is not error-free (Sakkas et al., 2018), hence all new technology coming into the laboratory ought to reduce risk of errors happening.

Study design, size, duration: Failure mode effects analysis (FMEA) was carried out on the workflow integration into an IVF centre (>500 cycles per annum) to evaluate the possible procedural risks of manual semen analysis compared to a digitalised pathway. Possible sources of error were identified, and the Risk Priority Number (RPN), a product of likelihood, severity and detection of incidence was associated with each risk, as previously described by Rienzi et al., 2015.

Participants/materials, setting, methods: Using a systematic decision-making approach to quantify the value of incorporating the use of a robotic system (Mojo AISA) for semen analysis.

Main results and the role of chance: Five process phases were identified for conventional specimen analysis. There were eight associated process steps and 29 failure modes, among which 13 risks were given a moderate (RPN 15-50, i.e. data entry errors, incorrect count and sperm classification) and three were severe RPNs (RPN>50), resulting in reduction in efficacy of treatment. Protocol using the robotic system resulted in a reduction of process phases to four and failure modes to 16, with four moderate and none severe RPNs. Implementation of the robotic system improved workflow by optimising time in motion for the IVF specialist and further reducing active time by at least 30%.

Limitations, reasons for caution: FMEA is a proactive method to identify potential incidents and help to develop strategies to mitigate risks. Ultimately, this forms part of a scheme for responsible development. The likelihood of incidences and time analysis were estimated based on clinical experience. Risks inherent to sample handling remained present.

Wider implications of the findings: The robotic system has the potential to eliminate risks that exist when manually inputting data to electronic medical records, whilst offering support to IVF specialists.

P-013 Evaluation of the efficacy of a short course of multidose menotropins in the treatment of male infertility in real clinical practice

S. Krasnyak[1], O. Apolikhin[2], G. Mskhalaya[3], S. Bogolubov[4]

[1]N. Lopatkin Scientific Research Institute of Urology and Interventional Radiology - branch of the National Medical Research Radiological Center of the Ministry of Health of Russian Federation, Department of Andrology and Human Reproduction, Moscow, Rus
[2]N. Lopatkin Scientific Research Institute of Urology and Interventional Radiology - branch of the National Medical Research Radiological Center of the Ministry of Health of Russian Federation, Directorate, Moscow, Russia C.I.S.
[3]European Medical Center, Andrology, Moscow, Russia C.I.S.
[4]Federal State Budgetary Institution "National Medical Research Center of Endocrinology" of the Ministry of Health of the Russian Federation, Andrology, Moscow, Russia C.I.S.

Study question: Is it possible to establish prognostic criteria for response to short course of multidose menotropin therapy in men with sperm pathology.

Summary answer: We found the increase of the effectiveness of menotropins with an increase in the duration of their use and an increase in dosage.

What is known already: Currently, menotropins are widely used to treat male infertility, both to stimulate spermatogenesis and to compensate for hormonal imbalance. But the actual practice of using menotropins may differ from the recommendations given by the manufacturer. Therefore, observational programs are particularly important, which allow assessing the effectiveness of a drug in routine practice. In real-world practice, hormonal treatment of the infertility is often carried out during the preparation of a couple for IVF and lasts no more than 4-6 weeks. At the same time, there is almost no scientific data in the literature of the effectiveness of such short treatment regimens.

Study design, size, duration: The study was designed as a multicentre, prospective, observational cohort study. The study included 1117 men with infertility enrolled between January 2020 and April 2021.

Participants/materials, setting, methods: The study included men with the absence of pregnancy during 12 months of regular unprotected sexual activity. The average duration of infertility was 20.6 months. As a treatment, men received multidose menotropin at a dosage of 75 IU, 112.5 IU or 150 IU every other day with hCG 2000 IU 2-3 times a week. Sperm parameters and hormones (total testosterone, SHBG, LH, FSH, Inhibin B, estradiol) were evaluated before treatment and 4 weeks after.

Main results and the role of chance: The age of the patients was 18 to 65 years (33.6 ± 7.0 years). The sperm concentration after 1 month of treatment increased by 23.8% from 17.6 ± 18.1 to 23.1 million/ml, the total sperm count increased by 32.1% from 40.2 ± 41.7 to 53.1 ± 49.1 million, progressive motility increased on average from 26.5 ± 16.2 to 32.0 ± 16.5%, the proportion of morphologically normal spermatozoa increased from 2.3 ± 2.5 to 3.0 ± 2.7 %. The level of total testosterone increased by 33.3% from 11.1 ± 4.6 to 14.8 ± 6.3 nmol/l. The levels of Inhibin B and estradiol did not change significantly. In a comparative analysis of the effect of dosage on the parameters of the ejaculate, the dose of 112.5 IU showed the greatest effect.

Limitations, reasons for caution: The main limitation of this study is the large heterogeneity of enrolled patients. There will be a very large variability in the age of men, as well as the severity of deviations from the norm in the analysis of ejaculate.

Wider implications of the findings: Thus, multidose menotropin, already when used for 4 weeks, can significantly improve the quality of the ejaculate (concentration, total count, progressive motility, morphology). In case of

insufficient effectiveness of a short course (1 month), it is advisable to continue treatment for at least 3 months or increase the dosage.

Trial registration number: not applicable

P-017 Validation of origami microscope "Foldscope" as a preliminary screening tool for male infertility

J. Errazuriz[1], C. Carlos[1], S.M. Alvaro[1], F. Isabel[1], S. Pablo[1], G. Patricio[1], D. Patricio[1]

[1]*Clínica Alemana, Departamento de Ginecología y Obstetricia- Facultad de Medicina- Clínica Alemana, Santiago, Chile*

Study question: Is there a concordance between the new optical microscope based on origami (Foldscope) with a traditional microscope for semen analysis as a screening method?

Summary answer: There is a 91% direct concordance between the foldscope and a traditional microscope as screening for initial approximation to male infertility.

What is known already: Semen analysis is a key element on men fertility evaluation. In order to obtain a semen sample, patients have to assist to a fertility clinic where the sample is analyzed. However, due to either time or distance problems, many patients cannot attend to fertility clinics. On the other hand, Foldscope is an origami-based microscope that can provide over 2000x magnification, and it can be attached to a smartphone and take photos and videos, which can be sent to fertility specialists for analysis. This technology might provide important information about semen status, especially in areas with limited fertility care access.

Study design, size, duration: A retrospective observational study was carried out, we included semen samples obtained by masturbation from volunteers were analyzed for count, concentration, and motility from patients who were undergoing a fertility study between November 2021 and November 2022 in Clínica Alemana, Santiago, Chile.

Participants/materials, setting, methods: A total of 188 human semen samples were evaluated by a single embryologist under a standard microscope and later used the same sample to make a cell phone video with Foldscope. This information was randomized and the videos were subsequently analyzed by the same embryologist blindly. Finally, the matching of the results was carried out.

Main results and the role of chance: Moderate and significant positive correlation for concentration calculated as $>$ or $<$ 15 million/ml between Conventional Microscopy and Foldscope (correlation coefficient= 0.67, $p <$ 0.005) Sperm motility for progressives A+B recorded with Foldscope demonstrated a significant correlation with the traditional microscope results (correlation coefficient = 0.69, $p < 0.005$). Finally, the concordance for the sperm count between both methods was 91%, with a kappa index of 0.66 ($p < 0.0001$).

Limitations, reasons for caution: One of the most important limitations of semen analysis by foldscope is that it must be interpreted by an embryologist, which means that the images must be sent to a specialized center.

Wider implications of the findings: In countries with few economic resources and not many options to for reproductive medicine centers, the use of the foldscope microscope as a screening as an initial approximation to male fertility allows a quick and economical immediate referral to men with reproductive problems.

P-018 Structural and biocompatibility analysis of gold nanoparticle integrated polymeric scaffolds for infertility diagnosis

B.A. Andone Rotaru[1,2,3], M. Girlovanu[3], A. Vulpoi[1], I. Botiz[1], S. Boca[1,4]

[1]*Babes-Bolyai University, Interdisciplinary Research Institute in Bio-Nano-Sciences, Cluj-Napoca, Romania*
[2]*Babes-Bolyai University, Faculty of Physics, Cluj Napoca, Romania*
[3]*VenusMed SRL, Human Assissted Reproduction Laboratory, Cluj Napoca, Romania*
[4]*National Institute for Research and Development of Isotopic and Molecular Technologies, Molecular and Biomolecular Physics, Cluj Napoca, Romania*

Study question: Can infertility diagnosis and sperm selection be improved by using bio- nanotechnologies?

Summary answer: Gold nanoparticle integrated biopolymeric scaffolds show good biocompatibility when interacting with human sperm cells, being suitable to be used as cell sorting and biosensing platforms.

What is known already: Microfluidic platforms are used in sperm selection for increasing the *in-vitro* fertilization success but they are limited by the exclusive analysis of sperm cell motility. The integration of microfluidic platforms with nanomaterials such as nanopatterned substrates can greatly enhance the selectivity and the sensitivity of the detection. The accuracy can be further improved by employing the intrinsic properties of gold nanoparticles (optical properties, high biocompatibility, surface chemistry favoring the conjugation of specific biomolecules), which makes them suitable for the successful development of precise and reliable detection assays, so far used to a limited extent in infertility research and clinical approaches.

Study design, size, duration: Concentration, motility and morphology of spermatozoa were analyzed in semen samples collected for spermogram. The normozoospermic and teratozoospermic samples were selected and prepared by density gradient centrifugation. The sediment obtained contained 100% motile spermatozoa, which were incubated on the thin films for 24h. After 24h, the probe from each incubation dish was collected and the survival rate was analyzed using the Makler chamber.

Participants/materials, setting, methods: Thin films of atactic polystyrene, chitosan and mixtures of each of the two polymers with gold nanoparticles were used to produce scaffolds of microchannels. The substrates were morphologically characterized by optical microscopy, scanning transmission electron microscopy and atomic force microscopy. Normozoospermic and teratozoospermic sperm samples were collected and incubated on the scaffolds. After 24h incubation, the viability was assessed by counting the motile spermatozoa under microscopic observation. Statistical analysis was performed using two-way ANOVA test.

Main results and the role of chance: Analysis of the sperm cell viability incubated on the polymeric scaffolds revealed good biocompatibility with higher survival rate in the case of chitosan-gold nanoparticle integrated samples. In multiple comparisons of normozoospermic samples, the survival rates of the sample incubated on the chitosan thin films to the control sample were 18% to 80% (-62%) ($p = 0.0143$), 16.66% to 45% (-28.34%) ($p = 0.0143$), 0% to 15.38% (-15.38%) ($p = 0.0239$), 4.76% to 55.35% (-50.59%) ($p = 0.0239$). In multiple comparisons of teratozoospermic samples, the survival rates of the sample incubated on the chitosan thin films to the control sample were 14.67% to 41% (-26.33%) ($p = 0.0143$), 0% to 44.82% (-33.82%) ($p = 0.0239$). For polystyrene, the viability was 0% which excludes its further use in infertility-related assays due to its high cytotoxicity. Overall, the colloidal gold nanoparticles integrated into the polymeric matrix improved the biocompatibility of the films. For example, citrate gold nanoparticles of spherical shape and sizes of about 20 nm increased the survival rate of normozoospermic samples, while PEGylation of nanoparticles showed further improvement of the biocompatibility. The influence of the particle type, composition and coating material onto the spermatozoa viability is currently under investigation for optimizing the effectiveness of the polymeric scaffolds.

Limitations, reasons for caution: NA

Wider implications of the findings: Due to the unique properties of gold nanoparticles, the nanoparticle-polymer scaffold systems have the potential to

become the foundation of a precise biosensor that can enhance the accuracy of the current approaches in infertility assessment.

P-019 Short ejaculatory abstinence time is associated with higher pregnancy and live birth rates and improved DNA fragmentation index (DFI): A Systematic Review

F. Sørensen[1], L. Magnusson Melsen[2], S. Soltanizadeh[3], J. Fedder[1]

[1]*Odense University Hospital, Centre of Andrology & Fertility Clinic- Department D, Odense, Denmark*
[2]*Copenhagen University Hospital, Obstetrics and Gynecology- Fertility Clinic, Herlev, Denmark*
[3]*Zealand University Hospital, Gynaecological Department, Roskilde, Denmark*

Study question: Does short ejaculatory abstinence time (EA) improve DNA fragmentation and reproductive outcomes compared with long EA following assisted reproductive technology (ART)?

Summary answer: Shorter EA is associated with improved pregnancy and live birth rates following ART and lower DFI compared with longer EA at different cut-off points.

What is known already: When spermatozoa pass the epididymal tract, they are exposed to reactive oxygen species (ROS). ROS is known to cause DNA fragmentation. Testicular sperm has a lower DNA fragmentation when compared to ejaculated sperm, which indicates that DNA fragmentation is increased during the transition and storage in the epididymal duct. There are studies that suggest that a high DFI is associated with poor pregnancy and live birth rates following ART. WHO recommends 2-7 days of EA prior to semen collection; however, several recent studies have reported a correlation between shorter EA and improved reproductive outcomes and DFI.

Study design, size, duration: A systematic review was conducted according to the PRISMA guidelines and registered in PROSPERO (CRD42022379039). The electronic databases PubMed, Embase and Cochrane were searched for eligible studies by a research librarian in April 2022. Additional articles were manually retrieved after reviewing the reference lists from relevant publications.

Participants/materials, setting, methods: Two authors independently screened studies based on the eligibility criteria; studies including men referred to fertility treatment undergoing short and long EA reporting data on pregnancy rate, live birth rate and DFI. Study demographics, population characteristics and data on study outcomes including statistical analyses were extracted. Risk of bias in each study was evaluated according to The Scottish Intercollegiate Guidelines Network (SIGN). Any disagreements were resolved by a third author.

Main results and the role of chance: Out of 1237 studies initially identified, 24 of them met eligibility criteria and were included in the review with a total of 14.173 cases. The studies included in this review were conducted in Asia, North and South America and Europe. The cause of referral to fertility treatment includes both male, female, mixed and unexplained infertility. The EA varied from less than a one hour to as long as 15-20 days.

Nine of the 13 studies investigated the influence of varying EA on pregnancy rate, found a significantly higher pregnancy rate with short EA compared with long EA, five with EA as short as one day or less. Three studies evaluated live birth rates and found a significantly higher live birth rate when comparing short EA with long EA. Eleven of the 15 studies that reported DFI found significantly lower DFI with short EA compared with long EA. EA of one day or less were associated with the lowest rates of DFI in the studies. In general, pregnancy rate, live birth rate and DNA fragmentation are likely to be improved with short EA compared to long EA.

Limitations, reasons for caution: Many of the included studies used different EA intervals, leading to heterogenous data, and therefore, only allowed limited conclusion to be formulated regarding the ideal timeframe of EA. Four studies scored poorly in SIGN methodology checklist due to confounding and population size, suggesting their findings to be treated with caution.

Wider implications of the findings: Even though it is difficult to make a clear recommendation on the ideal timeframe for EA because of the heterogenous abstinence periods, this review suggest decreasing the EA limits of 2-7 days as recommended by WHO to improve pregnancy rate and decrease DNA fragmentation in semen, followed by ART.

P-020 Association between male age and the frequency of sperm abnormalities

M. Handzhiyska[1], D. Parvanov[1], R. Ganeva[1], M. Ruseva[1], V. Georgieva[2], S. Gogeva[2], D. Velikova[2], G. Stamenov[3]

[1]*Nadezhda Women's Health Hospital, Research and Development, Sofia, Bulgaria*
[2]*Nadezhda Women's Health Hospital, Andrology, Sofia, Bulgaria*
[3]*Nadezhda Women's Health Hospital, Obstetrics and Gynaecology, Sofia, Bulgaria*

Study question: Does advancing male age influence the frequency of occurrence of sperm abnormalities?

Summary answer: Advancing male age was associated with increased incidence of certain head and tail defects – elongated head, nuclear vacuoles, and coiled tail.

What is known already: Evaluation of male reproductive potential is based mainly on sperm motility and sperm morphology. Morphological sperm features serve as a reliable indicator in predicting the fertilizing capacity of sperm. Nowadays, there are various sperm selection techniques based on sperm morphology. However, advancing male age has been associated with decrease in semen quality. Therefore, the aim of this study was to examine the effect of aging on the frequency of occurrence of sperm abnormalities.

Study design, size, duration: This retrospective study includes 3980 men aged between 15 and 72 years, with a mean of 36 years. Semen samples were collected between October 2015 and December 2022 in a private in-vitro hospital. Men were divided into three groups according to their age: 1) from 15 to 25 years ($n = 144$), 2) from 25 to 45 years ($n = 3447$), and 3) over 45 years ($n = 393$).

Participants/materials, setting, methods: Sperm morphology was evaluated according to the Kruger's strict criteria. Totally, 23 types of abnormalities were determined. Head defects included small, large, amorphous, elongated, round, pear-shaped, double, detached head, acephalic cells, small or large acrosomal areas, and spermatozoa without acrosome. Midpiece defects included thick, thin, bent, asymmetric midpiece and cytoplasmic droplets. Tail defects included short, coiled, and double tail. Acrosomal vacuoles and nuclear vacuoles were also evaluated. Statistics: ANOVA, followed by LSD post-hoc test.

Main results and the role of chance: The results are presented as mean ± SD. Among the studied population the percentage of normozoospermic men was 44%, while the percentage of teratozoospermic semen samples was 56%. The total mean frequencies of occurrence of head, midpiece and tail abnormalities were 85.9 ± 7.9%, 34.1 ± 12.8% and 4.7 ± 5.1%, respectively. Only 3 (13%) of the analysed 23 types of sperm abnormalities were significantly more common with advanced male age – elongated head, nuclear vacuoles, and coiled tail.The frequency of occurrence of elongated head differed significantly between the age groups 1-2, and 1-3: 11.38 ± 10.1% vs. 13.79 ± 11.58%, $p = 0.015$, and 11.38 ± 10.1% vs. 14.4 ± 11. 8%, $p = 0.008$, respectively. No difference in the incidence of this defect was observed between groups 2 and 3 ($p > 0.05$).Furthermore, the frequency of nuclear vacuoles significantly increased with age as observed in the following age group comparisons 1-2, 1-3, and 2-3: 4.28 ± 4.93% vs. 5.4 ± 6.1%, $p = 0.04$, 4.28 ± 4.93% vs. 6.48 ± 7.89%, $p < 0.001$, and 5.4 ± 6.1% vs. 6.48 ± 7.89%, $p=0.001$, respectively.Finally, coiled tail was observed more frequently in age groups 2 and 3 compared to age group 1: 13.79 ± 11.58% vs. 11.38 ± 10.1%, $p < 0.001$, and 14.4 ± 11. 8% vs. 11.38 ± 10.1%, $p < 0.001$, respectively.

Limitations, reasons for caution: This is a single-institution retrospective study.

Wider implications of the findings: The findings of this study showed that aging is associated with an increased percentage of several sperm abnormalities: spermatozoa with elongated head, nuclear vacuoles, and coiled tail. Further studies are required to clarify the negative impact of aging on spermatogenesis leading to morphological defects.

Trial registration number: NA

P-021 A novel SNP in HUWE1 promoter confers increased risk of NOA by affecting the RA/RARα pathway in Chinese individuals

X. Zhang[1], X. Shan[2], G. Huang[3], W. Xu[3]

[1]*Department of Obstetrics/Gynecology- Joint Laboratory of Reproductive Medicine SCU-CUHK- Key Laboratory of Obstetric- Gynecologic and Pediatric Diseases and Birth Defects of Ministry of Education- West China Second University Hospital-Sichuan Universi*
[2]*Sichuan University- Chengdu-China., West China School of Basic Medical Sciences & Forensic Medicine-, Chengdu, China*
[3]*Department of Obstetrics/Gynecology- Key Laboratory of Obstetric- Gynecologic and Pediatric Diseases and Birth Defects of Ministry of Education- West China Second University Hospital, Sichuan University, Chengdu, China*

Study question: The present study aimed to investigate the role of HUWE1 in non-obstructive azoospermia (NOA) etiology and germ cell differentiation.

Summary answer: An SNP mutation in *HUWE1* promoter region downregulates HUWE1 expression in NOA patients, the genetic polymorphisms of *HUWE1* are related to the pathogenesis of NOA.

What is known already: HUWE1, a ubiquitin ligase, is crucial to the development of male reproductive system and embryonic development. However, the specific role of HUWE1 in regulating germ cell differentiation is unclear, and clinical evidence for the relationship between HUWE1 and the pathogenesis of male infertility is lacking.

Study design, size, duration: 190 NOA Chinese patients were recruited and analyzed single nucleotide polymorphisms (SNPs) in *HUWE1* gene.

Participants/materials, setting, methods: Regulation of *HUWE1* gene expression by *RARα* factor was evaluated by performing ChIP assay, EMSA, and siRNA-mediated *RARα* knockdown. We used C18-4 cells to determine whether HUWE1 participated in RA-mediated RARα signaling and performed luciferase assay, CCK-8 assay, immunofluorescence staining, RT-qPCR, and western blot analysis. The expression level of *HUWE1* and *RARα* was evaluated in clinical samples obtained from NOA or obstructive azoospermia (OA) patients using RT-qPCR.

Main results and the role of chance: We explored the mechanism by which polymorphism of the *HUWE1* promoter leads to spermatogenesis disorders, and focused on the identification of mutations in the SNP site of the *HUWE1* regulatory sequence among patients with NOA, which may influence HUWE1 expression. The results of in vitro experiments showed that RARα binds to the *HUWE1* promoter region and regulates its expression. However, the regulatory effect of *RARα* weakened following introduction of the mutation into the *HUWE1* regulatory sequence. The expression of spermatogonial differentiation-related gene *STRA8* was impaired, and γH2AX foci accumulated following inhibition of *HUWE1* gene expression using siRARα. Finally, to determine whether *HUWE1* expression was important in patients with NOA, its expression was verified using testicular puncture samples collected from patients with NOA and the results revealed that *HUWE1* expression was abnormal ($P < 0.01$). In addition, *RARα* expression was significantly downregulated ($P < 0.001$). Overall, our result support the hypothesis that *HUWE1* expression is induced by the RA/RARα signaling pathway and it inhibit γH2AX foci accumulation, thereby considerably promoting sperm differentiation and meiotic prophase.

Limitations, reasons for caution: The effect of SNPs in HUWE1 on male infertility is further studied in a wider population.

Wider implications of the findings: Our study of HUWE1 and RA/RARα signaling pathway provides new information on the regulatory mechanism of spermiogenesis, suggesting that SNPs in HUWE1 promoter are etiological factors in patients with NOA and providing a rationale for further drug development to target HUWE1 in these patients.

P-022 The ICSI Outcome of Frozen Thawed Testicular Sperm Utilization in Azoospermic Men with AZFc Microdeletion

D.E. Bakırcıoğlu[1], C. Özcan[2], S. Tosun[3], N. Bayazit[3], S. Cengiz[3], U. Ulug[4]

[1]*SENSART Clinic, Urology, Istanbul, Turkey*
[2]*Ota-Jinemed Hospital, IVF Clinic, Istanbul, Turkey*
[3]*SENSART Clinic, Ob/Gyn, Istanbul, Turkey*
[4]*Haliç University Medical School, Ob/Gyn, Istanbul, Turkey*

Study question: What is the efficacy of frozen thawed surgically retrieved spermatozoa in azoospermic men with AZFc microdeletion undergoing Introcytoplasmic sperm injection (ICSI)?

Summary answer: The comparison between frozen thaw to fresh testicular sperm did not show statistically significant difference in terms of fertilization, blastocyst development and pregnancy rates.

What is known already: In male infertility, Y chromosome microdeletion (YCM) may be the cause up to 10% of men with oligozoospermia or azoospermia. AZFc region deletion was mostly detected in YCM. In men with azoospermia and AZFc deletion spermatozoa can be retrieved via testicular sperm extraction (TESE). Today, couples suffering azoospermia due to AZFc deletion may have genetically own child by using testicular sperm with ICSI. Because of the rare incidence of AZFc deletion, the outcome of ICSI cycles in which frozen thawed spermatozoa utilized for assisted conception has not been widely known.

Study design, size, duration: The data of 611 men with non-obstructive azoospermia (NOA) who underwent microTESE surgery between 2014 and 2022 was retrospectively analyzed. Assisted reproduction treatment (ART) outcome of couples whose men with AZFc deletion was further analyzed according to the fresh or frozen thawed spermatozoa usage for ICSI.

Participants/materials, setting, methods: All of the patients were genetically screened with karyotype and Y chromosome microdeletion analysis and microTESE operation was performed for testicular sperm recovery. The patients who diagnosed AZFc deletion and had successful sperm recovery divided to two groups according to cryopreserved or fresh sperm utilization for ICSI. The spouse and men age, fertilization rate, blastocyst development, pregnancy and live birth rate was compared between the groups.

Main results and the role of chance: Twenty-seven (4.4%) men were diagnosed YMC deletion in total of 611 men with NOA who underwent microTESE. Spermatozoa was successfully retrieved in 14 men (51.8%) men who were diagnosed AZFc deletion. The mean age of women and men were 30.5 (3.5) and 32.8 (4.1) years, respectively. Oocyte retrieval and ICSI were accomplished in 18 cycles. In 7 (38.8%) cycles fresh testicular spermatozoa and in 11(61.2%) cycles frozen thawed testicular spermatozoa were used. In one cycle, embryo transfer was cancelled due to total fertilization failure. In total, fertilization rate as 2PN/M2 oocytes was 57% (119/206). In 5 cycles cleavage stage embryos were transferred whereas in remaining 13 cycles blastocysts were transferred. Blastocyst development rate as day 5 blastocyst/2PN was 45.2% (42/95). Comparison of fertilization and blastocyst development rates according to fresh TESE spermatozoa and frozen thawed TESE spermatozoa groups were 63.2% vs 54.4% and 50.0% vs 38.7% respectively ($p > 0.5$ for both). Clinical and live birth rates per embryo transfer cycle were 57.1% vs 40.0% and 42.8% vs 30.0% respectively ($p > 0.5$ for both).

Limitations, reasons for caution: Fresh and frozen thawed groups demonstrated no statistical difference in terms of ICSI outcome. However, relatively reduced fertilization and blastocyst development rates should be interpreted cautiously because beta type error. Further data is needed to clarify this difference.

Wider implications of the findings: The best of our knowledge our study is the largest in literature comparing frozen thawed and fresh sperm utilization for ICSI in men with AZFc deletion. This data may help for physicians and couples to give decision diagnostic microTESE surgery and cryopreservation of sperm further ICSI treatment.

Trial registration number: Not applicable

Abstract citation ID: dead093.390
P-023 Weight loss in obese fathers improves hepatic lipid metabolism in offspring

T. Lin[1], X. Liu[2], H. Huang[1]

[1]*the International Peace Maternity and Child Health Hospital, Shanghai Key Laboratory of Embryo Original Diseases-, Shanghai, China*
[2]*Fudan University Affiliated Hospital of Obstetrics and Gynecology, Shanghai Key Laboratory of Embryo Original Diseases-, Shanghai, China*

Study question: Does paternal obesity affect offspring lipid metabolism and whether paternal weight loss can correct this effect?

Summary answer: The lipid metabolism of male offspring of obese fathers is abnormal, especially under the second hit, and paternal weight loss could rescue it.

What is known already: So far we have known that epigenetic modifications in spermatogenesis, are directly involved in the etiopathology of adult diseases transmitted by sperm. It was found that the offspring had more weight gain and impaired glucose tolerance and insulin resistance in adulthood, although they kept a normal diet through microinjecting ncRNA of obese mice spermatozoa into fertilized eggs from normal parents. The above evidence supported that epigenetic modifications can undertake part of the transmission from father to offspring.

Study design, size, duration: The 30 4-week-old C57 male mice were divided into three groups, normal diet as the control group (NCD) for 30 weeks, high-fat diet as the obese group (HFD) for 30 weeks, first high-fat diet for 10 weeks then low-fat and high-fiber diet as weight loss for 20 weeks (LFD). The male offspring of these groups were normally fed after weaning, then received a second hit (fasting for 36 hours or high-fat diet for 4 weeks).

Participants/materials, setting, methods: These offspring were divided NCD F1, HFD F1 and LFD F1, respectively. And in the fasting condition, the oil tolerance test and P407 test were carried out to detect the hepatic lipid metabolism function. HE staining and Oil Red O staining were performed on the liver sections of offspring to clarify the accumulation of lipid droplets in the liver. Liver autophagy was detected by western blotting and confocal microscopy.

Main results and the role of chance: Through oil tolerance test, it was found that TG and NEFA of HFD F1 increased at 1 hour and 3 hours after gavage, while LFD F1 significantly decreased. The P407 test further proved that under fasting conditions, the release of TG from the liver of HFD F1 was significantly weakened, and LFD F1 was restored. HE staining and Oil Red O staining of liver sections indicated that lipid droplets accumulated in the liver of HFD F1, while LFD F1 were significantly reduced. Under the second hit, the difference in liver lipid droplets among the three groups was more obvious. In addition, we found the levels of serum C-reactive protein, TNFα, and IL-6 increased in HFD F1 under the second hit, while LFD F1 could restore. It was found that the p62 of HFD F1 was higher and the ratio of LC3II to LC3I was lower than that of NCD F1, which indicated that HFD offspring liver autophagy was weakened through western blotting, and LFD offspring could restore liver autophagy. It was found that the co-localization of lipid droplets and lysosomes in the HFD offspring was reduced, which was more obvious under the second hit, while the LFD offspring could recover.

Limitations, reasons for caution: This study provides phenotypic evidence, however, the genetics of paternal disease remain to be explored.

Wider implications of the findings: The study provides new evidence that the father's lifestyle affects offspring metabolism, but this effect is not permanent and can be eliminated by changing the lifestyle.

Trial registration number: 82088102

Abstract citation ID: dead093.391
P-024 Effect of microsurgical varicocelectomy on fertility potential in patients with low sperm vitality

M. Mahdi[1], A. Majzoub[1], M. Arafa[1], H. Elbardisi[1], K. Khalafalla[1], S. Alsaid[1], A. Al Malki[1]

[1]*Hamad Medical corporation, Urology- Andrology and male infertility, Doha, Qatar*

Study question: Does microsurgical varicocelectomy improve semen parameters and fertility potential in patients with low sperm vitality?

Summary answer: Micro surgical varicocelectomy in patients with low sperm vitality is beneficial as it results in significant improvement in sperm count and progressive motility.

What is known already: Low sperm vitality (Necrozoospermia) indicates the presence of higher percentage of necrotic/ dead sperm in the ejaculate which can impair fertility potential. Varicocele induced testicular hyperthermia is among the most common causes of impaired semen quality, including necrozoosprmia. While many studies confirmed the beneficial effect of varicocelectomy on different semen parameters, very few have evaluated its role on sperm vitality in particular.

Study design, size, duration: A retrospective study of 1521 patients who underwent microsurgical sub inguinal varicocelectomy in our center from 2011–2021.

A total of 115 patients with clinical varicocele and low sperm vitality (<58%) were included.

Participants/materials, setting, methods: The exclusion criteria were history of genitourinary tract infection, exposure to heat, drugs or toxic compounds, hormonal disturbances or prior infertility related treatments. Patients demographics, and clinical data were collected, in addition to the pre- and post-operative Semen analysis (WHO 5th edition), sperm DNA fragmentation (Halosperm) and hormonal profile (estradiol, FSH, LH, Prolactin, Testosterone). Spearman's correlations and Wilcoxon Signed Ranked Test were used for data analysis.

Main results and the role of chance: Mean age was 34.9 ± 7.6 years. Varicocelectomy was done on left side in 75 patients and bilateral in 40 patients.

Sperm vitality was significantly negatively correlated with sperm DNA fragmentation (-0.618, $p = 0.000$) and abnormal sperm morphology (-0.435, $p = 0.000$, while it was significantly positively correlated with total motility (0.674, $p = 0.000$) & progressive motility (0.272, $p = 0.003$).

The median (IQR) sperm vitality pre-operatively was 41% (30-50) and the level increased post-operatively to 54% (31-63). There was a significant improvement in post-operative sperm count, progressive motility as well as LH and FSH levels. Improvements were also noted in total motility, normal morphology and sperm DNA fragmentation however the result didn't reach statistical significance.

Limitations, reasons for caution: The main limitation is the retrospective design of the study and it did not evaluate the pregnancy outcomes.

Wider implications of the findings: Improvement in semen parameters by microsurgical varicocelectomy in patients with low sperm vitality is important as it may change the management plan for patients and extend their fertility options to natural conception or intrauterine insemination instead of only intracytoplasmic sperm injection.

Trial registration number: not applicable

[5]*University College London, . Institute for Women's Health, London, United Kingdom*
[6]*CIBER Epidemiology and Public Health CIBERESP, Clinical Biostatistics Unit, Madrid, Spain*

Study question: What is the effectiveness and safety of various follicular phase ovarian stimulation protocols for intrauterine insemination (IUI) performed for any indication?

Summary answer: Significantly higher LBR/OPR was noted for gonadotrophins versus oral agents. Clomiphene+estrogen and gonadotrophins+letrozole demonstrated significantly higher OPR/LBR compared to no stimulation/stimulation with oral agents alone.

What is known already: Stimulated IUI is one of the most widespread fertility treatments offered for various indications. The rationale of stimulated IUI cycles follows the concept that more available oocytes for fertilisation would lead to increase chances of conception. Although several small pairwise comparisons are reported between different stimulation agents, there is no overall comparison using a network meta-analysis. Optimising the ovarian stimulation is an important step towards evidence-based guidelines. There is a cost- effect balance which should be kept in mind between achieving multi follicular growth to boost success rates and keeping the intervention safe in relation to multiple pregnancies.

Study design, size, duration: This review has been conducted in accordance with PRISMA guidelines and has been registered in PROSPERO (CRD42022300857). A computerized literature search was performed using EMBASE, MEDLINE and CINAHL as well as the Cochrane Central register of trials from database inception to May 2022. Randomized controlled trials (RCTs) were included. A random effects network meta-analysis within a frequentist setting was performed for the primary outcome live birth rate/ongoing pregnancy rate (LBR)/(OPR) and for multiple pregnancy rate.

Participants/materials, setting, methods: Couples/single women undergoing one or more cycles of stimulated IUI for various indications using partner's or donor sperm were included. The effect sizes of the outcome were estimated as odds ratio (ORs) and presented along with their 95% confidence interval (CIs). We used network plots to illustrate head-to-head comparisons. The superiority of the interventions was assessed; we calculated the probability of being the best, the mean rank, and the surface under cumulative ranking (SUCRA).

Main results and the role of chance: 57 RCTs were identified comparing stimulation protocols. These included oral agents (clomiphene, letrozole, anastrozole, tamoxifene, estrogen), injectable hormones (FSH, hMG +/- GnRH agonists and GnRH antagonists), alone or in combination, compared to other stimulation agent (s). The included trials randomized 11341 participants across 14 countries between 1994 and 2020. Fourteen trials were multi-centre and 43 (75%) were single centre. Comparisons were assessed in relation to LBR/OPR and in relation to multiple pregnancy rate in order to identify which combination is superior in achieving maximum success rates without compromising safety.

The comparison between ovarian stimulation with gonadotrophins and clomiphene had the most trials and participants and showed significantly higher OPR/LBR for ovarian stimulation with gonadotrophins compared to clomiphene (OR: 1.58, CI 1.24-2.02). No stimulation or stimulation with clomiphene or aromatase inhibitors demonstrated significantly lower OPR/LBR compared to clomiphene + estrogen (OR no stimulation: 0.29, CI 0.10-0.83; OR clomiphene: 0.27, CI 0.10-0.69; OR letrozole 0.30, CI 0.11-0.83) and gonadotrophins + letrozole (OR no stimulation: 0.22, CI 0.06-0.82; OR clomiphene: 0.21, CI 0.06-0.73; OR letrozole 0.23, CI 0.06-0.85).The safety of each ovarian stimulation strategy was assessed in terms of risk of multiple pregnancy.

Limitations, reasons for caution: Comparing different stimulation protocols for IUI is challenging in view of heterogeneity amongst included trials. Different add-ons could benefit specific patient groups but based on the available data, safe recommendations cannot be proposed according to subfertility diagnosis. Various add-ons, protocol variations and sperm preparation techniques could also affect outcomes.

Wider implications of the findings: Stimulation strategies aiming to increase success rates should be safe in terms of multiple pregnancy. Strict cancellation criteria and monitoring are required. Cost effectiveness, ease of administration, chances of cycle cancellation and couple's preferences should be taken into consideration. Future trials should take into account subfertility background and patient characteristics.

Trial registration number: not applicable

P-026 Effect of Microsurgical Varicocele Ligation in Patients with Isolated Oligozoospermia

A. Majzoub[1], M. Arafa[1], M. Mahdi[2], K. Khalafalla[2], A. Al Malki[2], S. Al Said[2], H. Elbardisi[2]

[1]*Hamad Medical Corporation and Weill Cornell Medicine - Qatar, Urology, Doha, Qatar*
[2]*Hamad Medical Corporation, Urology, Doha, Qatar*

Study question: Is varicocelectomy effective in improving the semen quality of patients with isolated oligozoospermia (IO)?

Summary answer: Varicocelectomy is a valid option for infertile men with clinical varicocele and documented IO considering the significant improvement in semen concentration.

What is known already: Varicocele is the leading correctable cause of male factor infertility and its surgical treatment has been associated with sound improvement in semen quality and fertility potential. While varicocelectomy is clearly indicated in men with abnormal semen parameters, its effect on men with isolated abnormalities is less commonly assessed.

Study design, size, duration: The charts of 1521 patients who underwent microsurgical subinguinal varicocelectomy for clinically palpable varicocele between 2011-2021 were retrospectively reviewed. Infertile patients with IO were included in the study group, while data from patients with oligoasthenoteratozoospermia (OAT) were utilized for comparison.

Participants/materials, setting, methods: Men with azoospermia, a history of genitourinary infection, and those utilizing peri-operative fertility medications were excluded. The collected data included patient's demographics, varicocele grade and veins' sizes, and their semen (semen analysis, WHO 2010; sperm DNA fragmentation, Halosperm) and hormone parameters before and up to 6 months after varicocelectomy. Data were analyzed using Wilcoxon Signed Ranks test and chi-squared tests. A p value <0.05 was considered significant.

Main results and the role of chance: A total of 96 patients with IO and 123 patients with OAT were included in the study. Patients with IO had a mean age of 32.5 $\pm$ 7 years, and an average testis volume of 15.6ml. The varicocele was of grades 2 and 3 in 58% and 38% of patients. Among the IO group, a significant increase in sperm concentration was identified postoperatively ($p=0.01$). Surprisingly, results revealed a significant decrease in sperm total motility, however, the postoperative median was still within the normal range (45.5%). No significant changes were observed in other semen or hormone parameters. When a comparison was made with the OAT group, 83% of patients with IO had an improvement in sperm concentration compared to 63.9% of patients in OAT group following varicocelectomy ($P=0.044$). However, a higher percentage of patients showed an improvement in total

motility among the OAT group (67.6%) in comparison to the IO group (42.9%) ($p = 0.04$).

P-026 Table I

	Preoperative	Postoperative	p value
Volume	3 (2-4.4)	3.35 (2.15-5)	0.99
Concentration	9.8 (5.5-12)	16 (6.83-24)	0.01
Total Motility	54.5 (46-60)	45.5 (28-62)	0.03
Prog. Motility	12.5 (5-29.75)	10 (5-25.5)	0.54
Normal morphology	30 (6-58.75)	42.5 (15.75-65)	0.87
DNA Fragmantation	20 (15-30)	25 (21-38)	0.11

Limitations, reasons for caution: Results were obtained from a relatively small sample size. However, varicocele treatment is not necessarily considered as the first treatment option in men with mild or isolated derangements in semen quality.

Wider implications of the findings: Results of this study shed the light on the effect of varicocele treatment in men with isolated oligozoospermia and hence may be beneficial for patient counselling in the clinic.

P-027 Absence of perinuclear theca ACTRT1 protein induces sperm head deformation and primary male infertility in humans

Q. Zhang[1], H. Jin[2], S. Long[1], X. Tang[1], W. Liu[1], W. Han[1], G. Huang[1], S. Chen[2], T. Lin[1]

[1]*Women and Children's Hospital of Chongqing Medical University, Center for Reproductive Medicine, Chongqing, China*
[2]*Beijing Normal University, Department of Biology- College of Life Sciences, Beijing, China*

Study question: Given that *Actrt1* knockout induces teratospermia, fertilization failure and severe male infertility in mice, will *ACTRT1* deficiency affect sperm morphology and male fertility in humans?

Summary answer: The ~110 kb microdeletion of X chromosome only including *ACTRT1* gene was identified inducing sperm head deformation and fertilization failure in an infertile Chinese man.

What is known already: The actin-related proteins, ACTRT1, ACTRT2, ACTL7A, and ACTL9, interact to form a multimeric complex in the sperm subacrosomal region and is vital for the attachment of acrosome to nucleus. The disruption of *ACTL7A* or *ACTL9* have been identified to cause acrosomal detachment, total fertilization failure and male infertility in humans and mice. *Actrt1*-knockout mice are severely subfertile also because of malformed sperm heads with detached acrosomes and a partial deficiency in fertilization. Loss/reduced expression and/or abnormal localization of PLCζ, a well-known sperm-borne activating factor, are identified in *ACTL7A/ACTL9* mutant patients as well as *Actrt1*-, *Actl7a*-, and *Actl9*-deficient mice.

Study design, size, duration: We recruited a cohort of 85 infertile men with teratospermia which is characterized by deformed sperm heads in the center for reproductive medicine from August 2019 to June 2022. Genomic DNA (gDNA) of patients was extracted from peripheral blood, then whole-exome sequencing and *in silico* analyses were performed to identify gene mutations. Morphological analysis, functional assays, and assisted reproductive therapy were performed in 2022.

Participants/materials, setting, methods: The *ACTRT1* deficiency was identified by whole-exome sequencing and confirmed by whole-genome sequencing, PCR and qPCR. Family members' gDNA was collected to define the hereditary mode. Papanicolaou-staining, scanning and transmission electronic microscopy were performed to reveal sperm morphologies. Western blot and immunostaining of spermatozoa were conducted to explore the pathological mechanism of the *ACTRT1* deficiency. Intracytoplasmic sperm injection (ICSI) combined with artificial oocyte activation (AOA) was applied for the assisted reproductive therapy of *ACTRT1*-deletion patient.

Main results and the role of chance: We identified a whole-gene deletion mutation of *ACTRT1* on Chromosome X in an infertile male with teratospermia, which was inherited from his mother. Papanicolaou-staining, scanning electronic microscopy, and transmission electronic microscopy showed the sperm head deformation owing to acrosome detachment, which mimicked the previously reported phenotype of *Actrt1*-knockout mice. The results of western blot and immunostaining suggested that ACTRT1 deficiency induced a down-regulated expression of ACTL7A and PLCζ proteins, but not ACTRT2, in human sperm samples. The detached acrosomes induced fertilization failure in assisted reproductive therapy of both *Actrt1*-knockout mice and the *ACTRT1*-deletion patient, which could be effectively rescued by ICSI combined with AOA.

Limitations, reasons for caution: Additional cases are needed to confirm the genetic contribution of *ACTRT1* mutations to male infertility with teratospermia and fertilization failure. In addition, the proband with *ACTRT1* deletion was with severe oligozoospermia and mild asthenozoospermia. The effect of *ACTRT1* mutations on sperm count and motility still need more investigation.

Wider implications of the findings: Our results reveal a gene–disease relationship between *ACTRT1* deficiency and human male infertility owing to teratospermia and fertilization failure. This report also describe a good fertility outcome of assisted reproductive therapy with ICSI and AOA for the *ACTRT1*-deficient patient.

P-028 Loss of the m6A methyltransferase METTL5 impairs spermiogenesis and male fertility

H. Chen[1], M. Zhang[1], S. Lin[2], W. Xu[3]

[1]*Medical School of Nantong University, Institute of Reproductive Medicine, Nantong, China*
[2]*The First Affiliated Hospital of Sun Yat-sen University, Center for Translational Medicine, Guangzhou, China*
[3]*West China Second University Hospital, Joint Laboratory of Reproductive Medicine SCU-CUHK, Chengdu, China*

Study question: Whether and how METTL5 regulates germ cell development during spermatogenesis.

Summary answer: METTL5 is required for spermiogenesis. Loss of METTL5 resulted in teratozoospermia and male infertility via reduced translation of acrosome and flagellum formation proteins.

What is known already: The roles of m^6A modifications on mRNA in spermatogenesis have been extensively studied. It was reported that METTL5 knockout mice showed the brain development defect and sterility of 16-week male mice. However, the detailed mechanism of METTL5 affecting male fertility remains elusive.

Study design, size, duration: Mettl5 KO mice were kindly gifted from Prof. Shuibin Lin of The First Affiliated Hospital of Sun Yat-sen University. Heterozygotes of Mettl5 mice were used to generate Mettl5 homozygous knockout mice. The phenotype of KO mice was assessed. Ribosomal sequencing, proteomics analysis and further validation of protein translation were performed to explore the mechanism.

Participants/materials, setting, methods: Fertility assessment, sperm parameter analyses, sperm nuclear morphology analysis, Transmission electron microscopy (TEM), tissue Collection and histological analysis, protein extraction and western blot analysis, immunofluorescence studies, cDNA synthesis and qRT-PCR, in vitro fertilization (IVF) were used in this study.

Main results and the role of chance: Here we reported that methyltransferase-like 5 (METTL5) is involved in spermiogenesis as a methyltransferase mediating m^6A modification on rRNA. Mettl5 knockout mice were infertile

with teratozoospermia. The acrosome in the sperm head was absent with reduced sperm motility. Furthermore, the fertilization ability of sperm in the IVF experiment failed. Mechanistically, the level of rRNA m^6A modification was significantly decreased in the testes of Mettl5 KO mice. The translational efficiency and protein levels of acrosome and flagellum formation proteins such as FSIP2, ODF2, GK2, PGK2, and AKAP4 were significantly reduced when METTL5 was depleted.

Limitations, reasons for caution: The METTL5 mutation in the patient with teratozoospermia was not examined in the present study

Wider implications of the findings: The rRNA m6A modification is also involved in regulating spermatogenesis by METTL5. This study highlights the critical role of rRNA epigenetic modifications during spermatogenesis and provides novel theoretical explanations for the m6A modifications.

[4]*Chung Shan Medical University, Department of Obstetrics and Gynecology, Taichung, Taiwan R.O.C.*
[5]*Chung Shan Medical University, Institute of Medicine, Taichung, Taiwan R.O.C.*
[6]*American Center for Reproductive Medicine, Global Andrology Forum, Moreland Hills, U.S.A.*
[7]*Cleveland Clinic Foundation, Emeritus Staff, Cleveland, U.S.A.*

Study question: Can centrifugation-free sperm separation device be used to simplify and standardize the selection of high-quality spermatozoa?

Summary answer: Centrifugation-free CA0 sperm separation device minimizes inter- and intra-operator variability and yields spermatozoa with comparable fertilizing properties in a variety of semen conditions.

What is known already: Centrifugation-based sperm separation methods have been used in assisted reproductive technology (ART) for many decades. However, the conventional methods are criticized for harmful effects due to centrifugation. To overcome the disadvantage, more noninvasive technologies have been developed and attempted to improve the sperm separation process, e.g., the formation of capillary bridge to select motile spermatozoa, migration-sedimentation technique to sort out functional spermatozoa, microfluidic sorting chip to isolate healthy sperm. While these methods provide alternatives for noninvasive sperm separation, the limitations such as inconsistency of semen quality improvement and lack of standardized procedure remain to be resolved.

Study design, size, duration: A randomized controlled trial of 76 men who sought ART treatment (Lee Women's Hospital, Taichung, Taiwan) from June to October 2022 was carried out. Seventy-six neat semen specimens were categorized into 27 normozoospermic specimens, and 49 non-normozoospermic samples (semen quality below any of the WHO 5th Edition lower reference values: concentration <15 million/mL, total motility <40%, or normal morphology <4%).

Participants/materials, setting, methods: Neat semen samples were separated for three replicates (replicate 1-3) using LensHooke® CA0 sperm separation device (Bonraybio, Taichung, Taiwan). Three operators (operators 1–3) performed CA0 procedures on each sample to test inter-technician variability. Interclass-correlation coefficient (ICC) between replicates as well as operators were evaluated. Pre-selection and post-selection semen quality were evaluated. The parameters included total motility, progressive motility, rapid progressive motility, morphology, DNA fragmentation index (DFI), and acrosome reaction rate (AR).

Main results and the role of chance: CA0 selects self-propelling spermatozoa within a microenvironment created by a microporous filter membrane. The procedure involves three pipetting steps: loading semen sample, adding sperm washing medium, and recovering the processed sample. Following the standard procedure, CA0 resulted in a low intra- and inter-operator variability and ICC values between replicates and different operators were all greater than 0.9, indicating an excellent reproducibility of CA0. In addition, significant higher levels of motility and normal morphology were observed in post-selection specimens either of normozoospermic or non-normozoospermic samples (pre-selection vs. post-selection, all $p < 0.0001$). In paired analysis of the advanced semen parameter, our study showed noteworthy results that CA0 significantly improved DFI from 18.2% to 2.6% for normozoospermic samples; such reduction was also found in non-normozoospermic sample processing, from 13.4% to 4.2% (both, $p < 0.0001$). The levels of AR were significantly reduced in normozoospermic samples (from 14.4% to 5.4%) and non-normozoospermic samples as well (from 12.8% to 5.0%) (both groups $p < 0.0001$). In conclusion, CA0 provides an efficient, noninvasive, standardized, and reproducible sperm separation model that CA0 diminishes the variations and ensures sperm quality.

Limitations, reasons for caution: The presented study was a pilot trial examining the sperm quality improvement. Follow-up analysis on IUI/IVF outcomes associated with the improvement in semen quality utilizing CA0 will be assessed in future studies.

Wider implications of the findings: CA0 provides multifaceted benefits covering consistent clinical outcomes, simplified and standardized procedure, user-friendliness, and cost reduction. We believe CA0 not only allows noninvasive sperm separation of clinically usable but also gives the possibility of standardization on sperm separation procedure.

P-030 Clinical outcomes of microdissection testicular sperm extraction (micro TESE) and intracytoplasmic sperm injection (ICSI) in non-obstructive azoospermia (NOA) with the history of cryptorchidism

T. Ishikawa[1], S. Mizuta[1], K. Yamaguchi[1], Y. Ohara[1], M. Doshida[2], T. Takeuchi[2], H. Matsubayashi[1]

[1]*Reproduction Clinic Osaka, Reproductive Medicine, Osaka, Japan*
[2]*Reproduction Clinic Tokyo, Reproductive Medicine, Tokyo, Japan*

Study question: What is sperm retrieval rate (SRR) by micro TESE and the clinical outcomes using testicular sperm in couples with the history of cryptorchidism?

Summary answer: NOA couples with the history of cryptorchidism had a higher SRR by micro TESE but lower clinical outcomes by ICSI compared of unexplained NOA.

What is known already: Undescended testis (UT) which is exposed to a higher temperature compared with the scrotal temperature is associated with impairment of germ cell maturation, and progressive Leydig and Sertoli cell atrophy, and subsequent infertility in adulthood. There have been very few studies of ICSI with a focus on, or large enough numbers to examine, the specific outcomes associated with male factor infertility, however improvement in sperm retrieval techniques including micro TESE and micromanipulation techniques, such as ICSI, has led to excellent fertilization and pregnancy outcomes of treatment cycles.

Study design, size, duration: We performed a retrospective study based on two reproduction centers in Japan and evaluated 1521 azoospermic patients in our clinics between September 2013 and December 2022. We investigated SRR by micro TESE in these patients and therefore aimed to evaluate the prevalence and the significance of ICSI outcomes with embryonic development in NOA couples with the history of cryptorchidism.

Participants/materials, setting, methods: We evaluated SRR of micro TESE, two pronuclei (2PN) oocyte rates, blastocyst development, good-quality blastocyst (Grade 3BB and above on day 5 by the Gardner scoring), and clinical pregnancy rates per embryo transfer (ET) in 72 NOA cases with the

history of UT, 953 cases of unexplained NOA, not including after orchidopexy, Klinefelter syndrome, cryptozoospermia, mumps orchitis, and 284 cases of obstructive azoospermia (OA). Statistical analysis was performed using unpaired t-tests and chi-squared tests.

Main results and the role of chance: SRR of first attempt micro TESE in UT (44/56=78.6%) was higher than unexplained NOA (160/748=21.4%) ($p < 0.001$). Spermatozoa were successfully retrieved in 13 of 22 (59.1%) UT group and 36 of 226 (15.9%) unexplained NOA who had previously undergone micro TESE with no sperm found. No correlation was found between serum FSH, LH, and T level with the success of sperm retrieval. Testicular volume and patient age at orchidopexy also did not affect the SRR for micro TESE. 2PN oocytes, blastocysts development, and good-quality blastocysts rates were 45.5%, 47.4%, and 18.9% in UT, 51.2%, 45.0%, and 20.9% in unexplained NOA, and 62.6%, 52.1%, and 23.7% in OA, respectively. Clinical pregnancy rates per ET were 29.3% in UT, 32.3% in unexplained NOA, and 41.6% in OA. Significant differences were only observed in 2PN oocytes between unexplained NOA and OA ($p < 0.05$) and clinical pregnancy between UT and unexplained NOA ($p < 0.05$), and OA and unexplained NOA ($p < 0.01$). Several UT patients showed a very small number of spermatozoa and even only immotile sperm of retrieved by micro TESE.

Limitations, reasons for caution: We included the patients only after a surgery of cryptorchidism, but not a delayed testicular descent without surgery. The cohort size of this study is not small, however, our screened population of azoospermic patients may be biased.

Wider implications of the findings: This study shows a high impact in micro TESE and ICSI outcomes with embryonic development for the NOA couples with the history of cryptorchidism. Our study emphasizes that history of cryptorchidism provides clinically valuable prognostic information to couples considering surgical sperm retrieval.

Trial registration number: not applicable

P-031 Presence of HPV 16 and HPV 18 in spermatozoa and embryos of mice

E. Mastora[1], A. Zikopoulos[1], T. Evangelou[1], I. Georgiou[1], K. Zikopoulos[1]

[1]*University of Ioannina, Department of Medicine, Ioannina, Greece*

Study question: The clarification of Human Pappiloma Virus (HPV) internalization in spermatozoa and early preimplantation embryos.

Summary answer: Spermatozoa are able to internalize constructs of cloned high risk HPV viruses either as integrated or as episomal DNA.

What is known already: Human Pappiloma Virus (HPV) is a non-enveloped, circular, double stranded DNA virus. Persistent infection with oncogenic HPV genotypes triggers HPV DNA integration into the host genome, eventually leading to chromosomal damage accumulation and genome destabilization in infected cells. Living spermatozoa of almost all species are able to take up spontaneously exogenous DNA and internalize a part of it into their nucleus.

Study design, size, duration: Taking into account the capability of sperm cells to integrate exogenous DNA into their genome, we sought to clarify HPV internalization into sperm genome. A total of 26 sperm samples were studied. The control group included 97 embryos. As for the HPV 16 and HPV 18 group, a total of 89 embryos were studied.

Participants/materials, setting, methods: Sperm was incubated with plasmid vectors containing the complete genome of human HPV 16 and HPV 18 tagged with the green fluorescent protein (GFP) gene, to investigate HPV 16 and HPV 18 integration in mouse spermatozoa. Oocytes were in vitro fertilized with preincubated spermatozoa to investigate HPV 16 and HPV 18 potential transfer to mouse embryos.

Main results and the role of chance: Spermatozoa were able to internalize constructs of cloned high-risk HPV either as integrated or as episomal DNA. Constructs of cloned HPV can also be transferred to mouse embryos, through in vitro fertilization of the oocytes by mouse spermatozoa.

Limitations, reasons for caution: Viral DNA integration into the sperm nucleus could not be directly demonstrated, but nevertheless integration is evident by GFP gene expression.

Wider implications of the findings: This study highlights the possibility of viral DNA transmission to the early embryo via sperm, opening new perspectives on the effect of HPV in reproductive cells. HPV persistence may impair sperm parameters, suggesting caution in the use of these cells for assisted reproduction techniques or sperm banking.

P-032 Exploration of the common genetic landscape of COVID-19 and male infertility

Y. Chen[1], P. Yuan[2], C. Liu[3]

[1]*Tongji Hospital- Tongji Medical College- Huazhong University of Science and Technology, Reproductive Medicine Center, Wuhan, China*
[2]*The First Affiliated Hospital of Zhengzhou University, Department of Urology, Zhengzhou, China*
[3]*Nanjing Drum Tower Hospital, Reproductive Medicine Center, Nanjing, China*

Study question: What is the cross-talk molecular mechanisms between COVID-19 and male infertility?

Summary answer: The present study identified and validated hub COVID-19-related differentially expressed genes (CORGs) in COVID-19 and male infertility, and systematically explored molecular interactions and regulatory features.

What is known already: COVID-19 has spread widely across continents since 2019, causing serious damage to human health. Accumulative research uncovered that SARS-CoV-2 poses a great threat to male fertility. SARS-CoV-2 has been confirmed to exist in semen specimens and seminiferous tubes in the testes of male COVID-19 patients. COVID-19 had an unfavorable influence on the semen parameters in infertile men, including sperm count, motility, and morphology. Male infertility (MI) is a common comorbidity for the COVID-19 pandemic.

Study design, size, duration: The study included the bioinformatic calculation, participant recruitment, specimen collection, and experimental validation in the university hospital.

Participants/materials, setting, methods: Four transcriptome data regarding COVID-19 and male infertility were downloaded from the GEO repository, and were divided for initial analysis and external validation. Differentially expressed genes analysis, GO and pathway annotation, PPI network, connectivity ranking, ROC analysis, and immune infiltration were performed to gain hub CORGs. We recorded medical information of COVID-19 patients with male infertility and matched controls, and harvested their sperm samples. Expressions of hub CORGs were detected through the qRT-PCR technique.

Main results and the role of chance: We identified 460 overlapped CORGs in both the COVID-19 differentially expressed genes (DEGs) and MI DEGs. CORGs were significantly enriched in DNA damage and repair-associated, cell cycle-associated, ubiquitination-associated, and coronavirus-associated signaling. Module assessment of PPI network revealed that enriched GO functions were closely related to cell cycle and DNA metabolism processes. Pharmacologic agent prediction displayed protein-drug interactions of ascorbic acid, biotin, caffeine, and L-cysteine with CORGs. After connectivity ranking and external validation, three hub CORGs (ENTPD6, CIB1, and EIF3B) showed good diagnostic performance (area under the curve > 0.75). Subsequently, three types of immune cells (CD8+ T cells, monocytes, and macrophages M0) were dominantly enriched, and 24 transcription factor-CORGs interactions and 13 miRNA-CORGs interactions were constructed in the network. Finally, qRT-PCR analysis confirmed that there were significant differences in the expression of hub CORGs (CIB1 and EIF3B) between the patient and control groups.

Limitations, reasons for caution: Diverse sequencing platforms and different ethnic subjects in the genetic data have influence on the accuracy of our analysis to some extent.

Wider implications of the findings: It is the first time for us to mine the genetic interrelationship between COVID-19 and male infertility. Our study provided new clues for the pathogenesis of these two diseases, and shared emerging potential biomarkers and drug targets for COVID-19-associated male infertility.

P-033 Impact of the sperm reactive oxygen species on Intrauterine Insemination outcome

N. Sayme[1], T. Krebs[2], D.A.H. Maas[3], M. Kljajic[4]

[1]*Team Kinderwunsch Hannover, Team Kinderwunsch Hannover, Hannover, Germany*
[2]*Team Kinderwunsch Hannover, IVF Labor, Hannover, Germany*
[3]*Team Kinderwunsch Hannover, Clinic, Hannover, Germany*
[4]*University Hospital Saarland, Klinik für Frauenheilkunde- Geburtshilfe und Reproduktionsmedizin, Homburg/Saar, Germany*

Study question: Does sperm reactive oxygen species values affect the pregnancy rate after Intrauterine Insemination (IUI)?

Summary answer: Sperm reactive oxygen species values affect pregnancy rate and can be used as a predictive marker for IUI outcome.

What is known already: Oxidative stress resulting from excessive production of reactive oxygen species (ROS) can profoundly affect the sperm and subsequent functional sperm integrity. Diagnostics to measure semen oxidative stress have been added to the 6th edition of the WHO laboratory manual for examining and processing of human semen, under advanced examinations. Although a semen analysis has classically been used as the gold standard for determining a man's fertility, basic sperm analysis alone cannot accurately predict infertility since between 6 and 27 % of men with normal semen parameters are infertile. Determination of oxidative stress in diagnosing infertility may contribute to better outcomes.

Study design, size, duration: This study was based on semen analyses of 50 male patients whose samples were used for IUI treatment between November 2022 and January 2023. The oxidation-reduction potential was measured using novel galvanostat-based technology, the MiOXSYS System. Briefly, 30 µL of liquefied semen at room temperature were applied to the MiOXSYS sensor. Both absolute ORP (mV) and normalized sORP values (mV/10 ^{6} sperm/ml) based on sperm concentration were calculated.

Participants/materials, setting, methods: Sperm analysis were performed according to the WHO laboratory manual sperm criteria (Sixth edition 2021). All participants followed a period of 3–5 days of sexual abstinence and had a diagnosis of unexplained infertility (normozoospermia). Ovarian stimulation for IUI cycle was initiated on the 5th day of menstruation by using recombinant gonadotropins. Clinical pregnancy was determined based on the Beta-hCG values. For statistical comparison between group values the Mann-Whitney U test was used.

Main results and the role of chance: According to the guidelines of the World Health Organization, all participants included in the study had normal BMI (21.85 ± 3.80 kg/m^2). The average age of the female patients included in the study was 33.9 ± 3.1 years while the average age of the male patients was 37.8 ± 4.8 years. Out of the 50 patients, 32% (N = 16) got pregnant. For the study propose sperm ORP and sORP values were compared between patients based on the pregnancy outcome. Statistical analysis showed a significant difference in ORP values. Patients with a positive pregnancy outcome after IUI had a lower ORP value compared to patients where IUI was not successful [25.65 [6.7-52.6] mV vs. 40.2 [6.3-109.8] mV, respectively, p = 0.02]. Additionally, normalized values according to the sperm concentration (sORP) were also significantly different between those groups [0.37(0.17-1.44) mV/10 ^{6} sperm/ml vs. 0.88(0.13-20.81) mV/10 ^{6} sperm/ml, respectively p = 0.006]. Due to the above-mentioned significant difference logistic regression analysis were performed, and the obtained results confirm that sperm ORP (p = 0.02) as well sORP (p = 0.016) significantly affects the pregnancy rate after the IUI procedure.

Limitations, reasons for caution: The limitation of the presented study was a relatively small patient cohort. Additionally, pregnancy was determined based on the beta hCG values, therefore future research should link ORP values and live birth rate as well.

Wider implications of the findings: In the present study suggests ORP as an additional parameter with diagnostic value to identify the best therapeutic approach concerning IUI in couples that show minimal or no impairments of the WHO semen parameter.

[2]*CooperSurgical, Genetics, Trumbull, U.S.A.*

Study question: What is the frequency of clinically significant results from expanded carrier screening (ECS) in a sperm donor applicant population and how should these be managed?

Summary answer: ECS results revealed clinically significant information for approximately 1 in 51 donor applicants, which warrant specific management considerations in the context of third-party reproduction.

What is known already: The American Society of Reproductive Medicine (ASRM) Practice Committee published guidance in January 2021 that outlines the recommended carrier screening approach for gamete donors. However, there is no additional direction related to results management including donor suitability, counseling, and informed consent. Prior studies have illustrated the high frequency of donors who are identified as carriers of one or more recessive disorders on an ECS panel; thus, excluding all prospective gamete donors identified as carriers for recessive conditions is not feasible or appropriate given the availability of reciprocal screening for the reproductive partner.

Study design, size, duration: A retrospective review of donor genetic screening records from July 2017 to December 2021 was performed. Relevant data was extracted and categorized by carrier screening result. Genetic counselors evaluated the health and reproductive risks to the potential donors (PDs) associated with being a carrier of a pathogenic mutation in each gene using published data, reference laboratory interpretations, and the professional health management guidelines.

Participants/materials, setting, methods: ECS was performed on sperm donor applicants as part of the routine donor qualification process. Testing was performed at an outside reference laboratory after participants provided written consent for genetic testing. The genes included on the ECS panel were analyzed using multiple methodologies. Specific methodologies varied based upon laboratory offerings at the time in which the potential donor entered the donor program.

Main results and the role of chance: A total of 966 PDs had ECS during the specified timeframe. Of these applicants, 19 total PDs (1.97%) were identified as having potentially significant health risks based on their ECS results. Of those 19 PDs, eleven were found to be either heterozygous or hemizygous for conditions that may convey significant health risks to carriers. Of these, nine were positive for a variant in a gene typically associated with an AR condition and two carried variants in genes associated with X-linked conditions. Eight additional PDs were found to be either compound heterozygous or homozygous for variants in a gene associated with an autosomal recessive condition.

Limitations, reasons for caution: Donor recruitment was limited to select major metropolitan areas in the U.S.; thus, donor applicants may not represent all ethnic groups or socioeconomic backgrounds. Additionally, this study described results from a single reference laboratory and does not illustrate the variation in ECS panels across genetic testing laboratories.

Wider implications of the findings: While this study examined ECS results in a donor applicant population, findings are also applicable to the general reproductive population and illustrate the necessity of informed consent and post-test counseling. In some cases, ECS may provide insight on potential future health risks and health management opportunities.

P-035 Effect of Varicocelectomy on normal semen in patients undergoing the procedure for indications other than fertility: evidence needed for counseling

K. Khalafalla[1], M. Mahdi[1], A. Majzoub[1], H. Elbardisi[1], S. AlSaid[1], M. Arafa[1]

[1]*Hamad Medical Corporation, Urology, Doha, Qatar*

Study question: Does microsurgical varicocelectomy impact normal semen parameters in fertile patients undergoing the procedure for indications other than infertility?

Summary answer: Micro surgical varicocelectomy does not alter the fertility potential of men with normal semen.

What is known already: Varicocele repair results in improvement in semen parameters and fertility potential in sub fertile patients with clinical varicocele. However, the procedure is also offered to patients with indications other than infertility including testicular pain, testicular size affection, or before army recruitment. Queries about the effect of varicocelectomy on fertility potential in this patient population have been raised but unfortunately not strongly backed by literature.

Study design, size, duration: A retrospective study of 1521 patients who underwent microsurgical sub inguinal varicocelectomy in our center from 2011–2021.

Participants/materials, setting, methods: A total of 435 patients with normal semen parameters and underwent varicocelectomy for indications other than infertility were included. Exclusion criteria were patients with infertility, abnormal semen parameters, and prior varicocelectomy. Patient demographics, clinical and laboratory data were collected. Semen analysis (WHO 5th edition), sperm DNA fragmentation (Halosperm) & hormonal assay were performed pre-operative and up to 6 months post-operative. Data were compared using Wilcoxon Signed Ranked Test. A p value <0.05 was considered significant.

P-035 Table I

	Pre-operative Median (IQR)	Post-operative Median (IQR)	P value
Volume	3 (2 -4.5)	3 (2 -4)	0.134
Concentration	39 (26 -57)	39.5 (23 -61.7)	0.872
Total Motility	59 (50 -65)	60 (48 -67)	0.405
Progressive Motility	22 (10 -37)	28 (10 -42)	0.499
Sperm DNA fragmentation	21.2 (16 -31.5)	24 (14 -38)	0.816
Normal Morphology	26 (8 -52)	37 (11.5 -55.5)	**0.042**
Estradiol	92 (70 -119)	96 (67 -120.5)	0.294
LH	3.7 (2.6 -4.9)	3 (2 -5)	0.827
FSH	3 (2 -4.2)	3 (2 -5)	0.704
Testosterone	16.8 (13.1 -21.6)	16.5 (13.5 -21.5)	0.475
Total Motile Sperm Count	66.5 (38.9 -119.2)	59.3 (30.8 -110.7)	0.140

Main results and the role of chance: The mean age was 32.8 ± 7.7 years. Varicocelectomy was performed on left side in 373 patients and bilateral in 62 patients. The majority of the study population had grade III varicocele on the left side. There were no statistically significant changes in semen volume, concentration, total & progressive motility, sperm DNA fragmentation, and hormonal profile after 6 months post varicocelectomy in comparison to initial baseline parameters (table 1). Only a statistically significant improvement in morphology was observed.

Limitations, reasons for caution: The main limitation is the retrospective design of the study. Long-term effect and conception rate were not evaluated.

Wider implications of the findings: Results of this work are beneficial during preoperative counseling of patients with normal semen undergoing varicocelectomy for non-fertility indications. Patients can be reassured that the procedure would not affect their fertility potentials negatively.

[3]*Center for Infertility and Human Reproduction CIRH-Eugin Group, Clinical Andrology, Barcelona, Spain*
[4]*Eugin Group, Research and Development, Barcelona, Spain*
[5]*Center for Infertility and Human Reproduction CIRH-Eugin Group, Medical, Barcelona, Spain*

Study question: Does male sexual abstinence affect clinical outcomes in oocyte autologous and donation cycles?

Summary answer: A reduced sexual abstinence period significantly improved ongoing pregnancy rates in oocyte donation cycles

What is known already: Among various factors affecting sperm quality, the period of sexual abstinence is often overlooked. The World Health Organization (WHO) has established specific standards for sperm analysis and advocates 2-7 days abstinence prior to ejaculation. Other guidelines (ESHRE and NAFA) limit this time to a shorter interval of 3-4 days. Studies suggest that a shorter abstinence period may reduce oxidative stress and improve motile sperm count. However, there is still no consensus on the optimal period of sexual abstinence for achieving the best clinical outcomes when undergoing assisted reproduction techniques (ART).

Study design, size, duration: Retrospective, single-centre study including 479 ICSI cycles (January 2018 to December 2021). First embryo transfer of the first cycle per patient for both autologous ($n=217$) and donor ($n=38$) oocyte cycles were analysed. Preimplantation Genetic Testing cycles and those employing microfluidic devices for sperm preparation were excluded as well as patients with abnormal karyotypes, uterine abnormalities and evidence of chronic infectious diseases (Hepatitis B, C or HIV).

Participants/materials, setting, methods: All cycles used male partner sperm. Two abstinence periods were compared: short ($\leq$ 2 days, $n=108$ and $n=16$) or long ($\geq$ 3 days, $n=109$ and $n=22$) for autologous and donor oocytes, respectively. Outcomes considered: seminal parameters; fertilized, 1PN, 3PN, >3PN and degenerated oocytes; implantation and ongoing pregnancy rates. Analysis of variance, Chi-square test and student t-test (Mann Whitney) were used to calculate p-values. A p-value of <0.05 was considered significant.

Main results and the role of chance: Mean paternal age was 34.9 and 35.2 years for autologous and oocyte donor cycles, respectively. Regarding sperm parameters, a significant increase in concentration was seen in the long abstinence group ($p=0.009$). There was a trend towards improved fertilization and implantation rates in the short abstinence group and also towards lower rates of 1PN, 3PN, >3PN and degenerated oocytes in oocyte donation cycles. Moreover, oocyte donation cycles linked to short abstinence, showed significantly higher ongoing pregnancy rates compared to those involving a long abstinence period ($p=0.015$). A similar trend was observed in autologous cycles.

Limitations, reasons for caution: The small sample size and retrospective design warrant careful interpretation.

Wider implications of the findings: Our findings suggest that the length of sexual abstinence may have an impact on sperm quality and clinical

outcomes. Reduced abstinence may improve ongoing pregnancy rates, potentially due to reduced levels of sperm DNA fragementation. New criteria for abstinence periods should be considered.

P-037 The extent of paternal effect: the blastocyst matters! A retrospective analysis of 1351 single, frozen-thawed embryo-transfers

C. Dolci[1], V.S. Vanni[1], E. Papaleo[1], L. Pagliardini[1], A.F. Ruffolo[1], G. Cermisoni[1], A. Salonia[1], S. D'Alessandro[1], E. Russo[1], V. Sangiorgi[1], M. Candiani[1]

[1]*IRCCS San Raffaele Scientific Institute, Gynecology/Obstetrics Department, Milan, Italy*

Study question: Is ongoing pregnancy rate (OPR) impaired by total motile count (TMC) values in IVF/ICSI cycles?

Summary answer: TMC does not affect the OPR in IVF/ICSI cycles.

What is known already: Studies exploring the paternal role and specifically the influence of sperm parameters on the IVF/ICSI outcomes led to contradictory results, especially after the blastocysts formation. If a negative impact of severe male infertility on fertilization rate, embryo morphology and blastocyst formation rate have been described by several studies, its effect on implantation rate (IR), OPR and live birth rate (LBR) is still debated. In this context, TMC is an useful and validated tool for sperm evaluation, combining three critical sperm parameters into a single indicator of sperm quality.

Study design, size, duration: Retrospective analysis of 1351 freeze-all IVF/ICSI cycles performed between January 2015 and June 2022 in the Reproductive Sciences Unit of Gynaecology/Obstetrics Department of San Raffaele Hospital in Milan, Italy.

Participants/materials, setting, methods: We included all the first, single, frozen-thawed transfers performed in the study period. Transfers of blastocysts obtained by frozen semen were excluded. Couples' characteristics, semen parameters and controlled ovarian stimulation data were collected. Semen quality was assessed using TMC and grouped into quartiles of TMC for the analyses. The primary outcome of the study was the evaluation of the effect of TMC on the implantation potential of the obtained blastocysts.

Main results and the role of chance: 1351 transfers were analyzed. Performing a logistic regression analysis adjusted for confounding factors (maternal age, number of oocytes retrieved and quality of transferred blastocysts), OPR was not influenced by TMC values [odds ratio (OR) = 1.00; confidence interval (CI) = 0.99-1.00; p = 0.5]. After grouping the male infertility population into quartiles of TMC, no significant differences in OPR were found between extreme quartiles (n = 339, TMC ≤4 million and n = 348, TMC ≥42 million respectively), even when adjusted for confounders [OR = 0.99; CI 0.73-1.35; p = 0.97]. Therefore, the implantation potential of the obtained blastocysts, once formed, seems to be independent from the sperm quality.

Limitations, reasons for caution: The major limitation of the study is the retrospective design. Additionally, although a positive correlation between TMC and pregnancy rate is well described, a TMC threshold for defining severe male infertility has not been yet identified.

Wider implications of the findings: With a larger sample size we confirmed the results of our previous study. Indeed, TMC did not demonstrated to impair OPR of blastocysts from infertile couples submitted to IVF/ICSI. Further data, such as pregnancy and obstetrics outcomes, would be necessary to better define the role of male infertility in reproduction.

P-038 Correlation between sperm DNA fragmentation index, semen parameters and Human Papillomavirus: an analysis conducted under World Health Organization 2021 guidelines

Study question: Following 6thWHO (2021), we analysed the correlation between DNA fragmentation index (DFI), Human papillomavirus (HPV), and seminal parameters, highlighting slow and rapid progressive motility alterations.

Summary answer: DFI rates and seminal parameters correlated with rapid, slow, and progressive motility. However, HPV-positivity caused the loss of association between DFI and slow progressive motility.

What is known already: HPV detection in semen samples has long opened an investigation into its influence on male infertility. Some studies indicate that HPV can affect sperm quality and DFI, while others have failed to find any correlation. With reference to 2010 WHO guidelines, our latest work highlighted how HPV positivity significantly impairs progressive motility, morphology, and immotile sperm rate. Since the latest 2021 WHO guidelines included the evaluation of slow and rapid progressive motility and DFI, we analysed if these new parameters and the other conventional parameters could be altered by HPV infection.

Study design, size, duration: From August 2021 to December 2022, 121 semen samples were collected from male partners of HPV-positive women attending in vitro fertilization (IVF). Every specimen underwent DFI evaluation, analysis of seminal parameters, and HPV test.

Participants/materials, setting, methods: Seminal samples were collected by masturbation after 3-5 days of sexual abstinence. The inclusion criteria were as follows: no other sexually transmitted infections, no genetic diseases, and no inflammatory disorders. Sperm concentration, morphology, non-progressive and immotile sperms, and both slow and rapid progressive motility were evaluated according to WHO 2021 guidelines. DFI analysis was assessed by sperm chromatin dispersion test (SCD), while HPV-DNA detection was performed using InnoLipa HPV Genotyping Extra II (Fujirebio, Tokyo, Japan).

Main results and the role of chance: Of the 121 semen samples tested, 60 (49.6%) were HPV-positive and 61 (50.4%) were HPV-negative. DFI rates showed a significant negative correlation with rapid progressive motility in both groups and a positive correlation with slow progressive motility in the HPV-negative group. Conversely, the significance of the correlation between DFI and slow progressive motility was completely lost in HPV-positive patients. Sperm concentration, normal forms and immotile spermatozoa percentages were correlated with both motility parameters in the HPV-negative group. Similar results were observed in HPV-positive samples, except for the normal form rate, which was not associated with slow progressive motility. In addition, the same samples displayed a negative correlation between non-progressive motility and rapid progressive motility, absent in HPV-negative samples. Significant associations were found also for the derived parameter of progressive motility, which was correlated with DFI, sperm concentration, immotile sperm, and normal forms rate in both groups. The results suggest how high DFI rates, in the presence or absence of HPV infection, could affect reproductive health through a consistent impairment of spermatozoa motility. In

particular, the distinction of slow and rapid progressive motility by WHO 2021 allows a deeper understanding of the possible correlations between DFI, semen parameters and HPV infection.

Limitations, reasons for caution: This is a preliminary study characterized by a small number of samples. Therefore, confirmation of these findings requires the enlargement of the patient cohort, which is already taking place.

Wider implications of the findings: Our results highlight how the introduction of the new WHO 2021 evaluation criteria, i.e. DFI, and slow and rapid progressive motility, provides additional information about sperm quality and the impact of HPV infection on it.

[5]*CHI de Poissy-St-Germain-En-Laye, Department of Reproductive Medicine, Poissy, France*

Study question: How should men with globozoospermia be managed in Assisted Reproductive Technologies (ART)?

Summary answer: IMSI (intracytoplasmic morphologically selected sperm injection), without oocyte activators (OA) allows to obtain a live birth, even when there is a mutation of DPY19L2 gene.

What is known already: Globozoospermia is a rare syndrome found in less than 0.1% of the infertile population. It is characterized by the presence of spermatozoa with round heads devoid of acrosomes. Two main genes are involved in the transmission of the disease: SPATA 16 and DPY19L2. Only Assisted Reproductive Technologies (ART) such as ICSI (intra-cytoplasmic sperm injection) and IMSI, with or without OA allow these couples to obtain pregnancies. There are no live births described after IMSI without OA in patients with a DPY19L2 mutation.

Study design, size, duration: Four infertile couples followed in the Department of ART at the Poissy Hospital Center, were studied between 2011 and 2022.All patients had total globozoospermia. Three patients were tested for the DPY19L2 gene mutation. Patients were managed in ART with the IMSI technique without the use of OA.

Participants/materials, setting, methods: The first patient had a homozygous mutation of the DPY19L2 gene. Two live births were obtained after IMSI.

The second patient was not DPY19L2 mutated. 2 IMSI were performed, resulting in a biochemical pregnancy.

The third patient had a homozygous mutation of the DPY19L2 gene. An IMSI was performed without obtaining a pregnancy, a second attempt is scheduled soon.

The fourth patient refused genetic testing and IMSI management. Sperm donation was performed without achieving pregnancy.

Main results and the role of chance: In this case series, we present the management of four globozoosperm couples in the Reproductive Biology and Andrology Department at the Poissy Hospital Center. We also present the first two live births after performing an IMSI, without OA, in a globozoospermic patient with a homozygous mutation of DPY19L2 gene. In fact, according to our review of the literature, 53 case reports or articles of patients having benefited from ART with or without OA have been reported in globozoospermic patients. In these couples, 60 children were born. However, no live births had been reported until now in couples managed in IMSI without OA, where men had globozoospermia with DPY19L2 mutation.

Limitations, reasons for caution: The use of OA to increase the membrane permeability of oocyte to calcium and increase fertilization rates. The highest number of live births in the globozoosperm population occurs after ICSI or IMSI with OA. There is no described live birth without the use of OA in a DPY19L2 mutated patient.

Wider implications of the findings: The use of OA remains debated and is not authorized in some countries. Although our study found low fertilization rates after IMSI, it's possible to obtain live births. The selection of spermatozoa with an acrosome outline at high magnification is thus an interesting alternative to the use of oocyte activators.

Abstract citation ID: dead093.407
P-040 The Role of ACE2 and DNA fragmentation index on covid-19 post infected, healthy and infertile men

A. Mohammed[1]

[1]*Alnahrain university, Applied embryology, Baghdad, Iraq*

Study question: to investigate the relationship between ACE2 and DNA fragmentation index and their impact on men's reproductive system in covid-19 post-infected patients.

Summary answer: the drastic effect of covid-19 on the male reproductive system might be due to elevated DFI and ACE2 levels.

What is known already: In the last two years, many studies had been devoted to uncovering the depraved impact of covid-19 by measuring ACE2 concentrations or sperm DNA fragmentation but no study was applied to measure both parameters, this study performed on both parameters to figure out the role of angiotensin-converting enzyme (ACE2) with seminal fluid parameters and DNA fragmentation index in covid-19 post infected men and infertile patient in comparison to healthy fertile men.

Study design, size, duration: This prospective cohort study was conducted from November 2021 to June 2022. one hundred and nine men who participated in this study.

Participants/materials, setting, methods: The participants were divided into four groups: post-infected men with Covid-19 who recovered from Covid-19 infection with a recovery interval of no more than three months from the time of symptoms onset and all were fertile married men, healthy fertile men who haven't been infected with Covid-19 in the last three months obtain normal seminal fluid parameters as control, The third group is composed of oligospermia, while the fourth group is constituted of azoospermia volunteers

Main results and the role of chance: In this study, the result showed that the seminal fluid parameters for post-infected men with covid-19; were demotion in sperm concentration, total count, motility, and morphology with a p-value < 0.001 when compared with healthy men. DNA fragmentation in post-infected men was 4 times higher than in non-infected and it was found that post-infected men had 10 times more ACE2 concentrations in comparison with healthy men. The study showed that in oligospermia and azoospermia volunteers own a high ACE2 level compared to healthy volunteers and that the oligospermia subjects have a significantly high sperm DNA fragmentation index.

In conclusion, the drastic effect of covid-19 on the male reproductive system might be due to elevated DNA fragmentation and ACE2 levels, and there is a statistically significant positive correlation between the DNA fragmentation index and ACE2 levels.

Limitations, reasons for caution: number of post-infected men with covid-19

Wider implications of the findings: 1- A positive relationship exists between DNA fragmentation index percentage (DFI) and angiotensin-converting enzyme level (ACE 2).

2- Covid-19 infection alters sperm parameters such as concentrations, total sperm count, motility, and morphology.

3- The percentage of DNA fragmentation rose significantly after covid-19 infection.

P-041 Enhancing Embryos of the Desired Sex in Couples Undergoing PGT-A while Minimizing Embryo Wastage

R. Elias[1], S. Cheung[1], P. Xie[1], Z. Rosenwaks[1], G.D. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Can we enhance the proportion of euploid embryos of the desired sex for couples undergoing ICSI and PGT-A with sex selection while reducing embryo wastage?

Summary answer: Using a novel sperm selection technique, we generated higher proportions of embryos and offspring of the desired sex without impairing clinical outcomes or offspring health.

What is known already: Although controversial, the wish for offspring of a specific sex is common in the U.S. Many couples, particularly those requiring IVF with PGT-A, request a euploid embryo of a specific sex. This is often associated with the generation of more conceptuses of the unwanted sex, resulting in embryo wastage. We propose utilizing a simple and safe sex selection technique (SST) to skew spermatozoa toward the desired sex so that concurrent embryos can be generated in higher proportions.

Study design, size, duration: Over a 7-year period, ejaculates from male partners of couples (n = 144) undergoing ICSI with PGT-A were processed using SST to enrich spermatozoa for their preferred sex. Standard sperm processing was carried out for couples undergoing ICSI exclusively to assess conceptus aneuploidy, comprising the control group (n = 1,440). The proportion of male and female spermatozoa in the initial and selected specimens, PGT-A results, and ICSI outcomes following frozen embryo transfer (FET) were compared between the two groups.

Participants/materials, setting, methods: A total of 1,584 couples were treated in 2,723 ICSI cycles. Standard sperm processing was performed for 1,440 couples who did not have offspring sex preferences, comprising the control. For 144 consenting couples, SST was used to enrich spermatozoa for either sex (IRB 1306014043). To confirm sex enrichment and ploidy, ≥1,000 sperm cells were screened by fluorescent in-situ hybridization (FISH) for nine chromosomes. Embryology and PGT-A outcomes were compared between the control and SST cohorts.

Main results and the role of chance: Couples (n = 1,440) from the control cohort (maternal age, 37.1 ± 4yrs; paternal age, 39.1 ± 6yrs) underwent 2,541 ICSI cycles, yielding an 80.1% fertilization rate (15,901/19,859). PGT-A confirmed that 46.6%(n = 4,479) of conceptuses were female and 53.4%(n = 5,132) were male. These couples achieved 76.2%(866/1136) implantation and 64.9%(737/1136) clinical pregnancy rates, resulting in 624 healthy deliveries (48% female, 52% male).

From the study cohort (n = 144), 79 desiring female offspring (maternal age, 37.9 ± 4yrs; paternal age, 40.8 ± 6yrs) obtained an 81.6% sperm sex enrichment. They underwent 98 ICSI cycles, achieving a 76.7%(792/1032) fertilization rate, resulting in a greater proportion of female embryos (79.1%, 351/444) than the control ($P<0.05$), of which 78.6% (276/351) were euploid. Following FET, 39 couples obtained a 79.5% (31/39) implantation rate, yielding 27 clinical pregnancies with deliveries, thus far, of 16 female singletons, all developing normally.

The remaining 65 couples (maternal age, 37.6 ± 3yrs; paternal age, 40.8 ± 5yrs) preferring male offspring obtained 80.8% male sperm enrichment and underwent 84 ICSI cycles, achieving a 74.9%(723/965) fertilization rate with a greater proportion of 79.3%(249/314) male embryos compared with the control ($P<0.05$), of which 66.3%(165/249) were euploid. Following FET, their implantation rate was 90.0%(36/40), yielding 25 clinical pregnancies that resulted in the deliveries, thus far, of 20 male singletons, all developing normally.

Limitations, reasons for caution: Although SST does not absolutely grant offspring of a specific sex, it allowed couples to obtain a greater proportion of conceptuses of their preferred genotype. This method does not replace PGT-A for sex selection, but rather enhances the generation of embryos of the desired sex, thereby reducing embryo wastage.

Wider implications of the findings: We confirmed a significantly higher proportion of conceptuses of the desired sex. Thus far, embryo developmental competence, aneuploidy rates, delivery rates, and offspring health were not impaired by SST-processed spermatozoa. This supports the safety of SST, rendering it effective and ethically palatable.

P-042 Sperm Selection Based on Speed Using Rheotaxis in a Parallel Array of Microfluidic Apertures

M. Yaghoobi[1], P. Xie[2], S. Cheung[2], O. Kocur[2], Z. Rosenwaks[2], A. Abbaspourrad[1], G. Palermo[2]

[1]Cornell University, Food Science And Technology, Ithaca, U.S.A.
[2]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Does selecting human spermatozoa using a dynamic microfluidic system impact semen parameters and genomic characteristics?

Summary answer: Flow rate adjustment in a dynamic microfluidic device selects spermatozoa with superior DNA integrity. It also appears to select a higher proportion of Y-chromosome-bearing spermatozoa.

What is known already: Mammalian spermatozoa demonstrate rheotactic motion against the flow. This is important in order to overcome the fluid drag force in the female genital tract to reach the oocyte. Sperm processing methods have been developed based on these principles; more recently, static and dynamic microfluidic devices have been tested due to the association between high progressive motility and greater genomic integrity. These devices also appear to have an impact on sperm sex selection.

Study design, size, duration: Human ejaculates (n = 7) were evaluated and simultaneously processed by density gradient centrifugation (DGC) or a novel microfluidic sperm sorter (MFSS) with an adjustable flow rate inspired by the constriction of the uterotubal junction. Concentration, motility, morphology, and SCF were assessed and compared between raw, DGC-, and MFSS-processed specimens. To identify differences in the SCF and the proportion of X- and Y-spermatozoa, spermatozoa isolated at different flow rates (150, 250, 350, and 450 µl/h) were evaluated.

Participants/materials, setting, methods: Ejaculates were evaluated by standard semen analysis according to WHO 2021 criteria. Following complete liquefaction, 1 mL of sample was used for DGC, and 0.8 mL of semen was used for the prototype MFSS at 0.2 mL for each flow rate. SCF was assessed by TUNEL assay with a normal threshold of ≤ 15%. Fluorescent in situ hybridization (FISH) was performed using X- and Y-chromosome probes.

Main results and the role of chance: A total of 7 men (35.4 ± 5 years) had the following semen parameters: volume of 3.3 ± 2 mL, concentration of 76.7 ± 33 $x10^6$/mL, 45.5 ± 1% motility, and a normal morphology of 3.2 ± 0%. When comparing the post-processing parameters between the two methods, DGC yielded a concentration of 49.9 ± 25 $x10^6$/mL and MFSS yielded a reduced concentration of 4.5 ± 5$x10^6$/mL ($P<0.0001$). DGC yielded 91.1 ± 1% motility and normal morphology of 3.2 ± 0.4%. Albeit at a cost of concentration, MFSS yielded spermatozoa with significantly higher motility (96.3 ± 3%; $P<0.0001$) and a higher proportion with normal morphology (4.0 ± 0.6%; $P<0.0001$). Moreover, the SCF of the raw sample was 9.4 ± 2.0%; although the SCF was 8.1 ± 3.6% with DGC, it was 4.5 ± 2% ($P<0.001$) with MFSS.

An analysis was performed within the different flow rates of the MFSS; a 250 µl/h flow rate yielded the highest recovery rate (42.0 ± 6%; $P<0.001$), highest concentration (5.6 ± 4 $x10^6$/mL; $P<0.01$), highest motility (97.0 ± 2.2%; $P<0.05$), and a normal morphology rate (4.3 ± 1%). The SCF for this flow rate was <3%. Surprisingly, we noticed that the proportion of Y-chromosome–bearing spermatozoa positively correlated to the flow rate,

suggesting that there may be a subtle difference in the kinetics of male and female spermatozoa.

Limitations, reasons for caution: Although our novel MFSS platform is a promising technique, it is costly and requires specific expertise and training. This is a limited observation and requires integration of clinical outcomes to prove its benefits.

Wider implications of the findings: A microfluidic device with a controlled flow rate allowed the fine-tuned selection of spermatozoa with superior hydrodynamic and kinetic characteristics and a higher genomic integrity. Once automated, this device may help to select spermatozoa with greater embryo developmental competence and be useful to isolate spermatozoa of the desired sex.

[2]*The Centre for Reproductive and Genetic Health, Fertility Clinic, London, United Kingdom*
[3]*University College London Hospital, EGA Institute for Women's Health-, London, United Kingdom*

Study question: To investigate the influence of paternal age on the live birth rates in oocyte recipient cycles

Summary answer: Increased paternal age appears to have a negative impact on oocyte recipient cycles when adjusted for sperm quality.

What is known already: While the effect of maternal age on ART outcomes is well established, the effect of paternal age is unclear. Even systematic reviews assessing the impact of paternal age in oocyte recipient cycles have yielded conflicting results. While Morris et al., 2020 could not demonstrate changes in miscarriage rates or live birth rates with increased paternal age, Murugesu et al., 2022 showed an adverse effect of increased paternal age on miscarriages but did not comment on live birth rates. The challenges of systematic reviews are the heterogeneity of the studies and the possible effect of laboratory and clinical practices.

Study design, size, duration: This retrospective cohort study was conducted at a single centre. A total of 449 IVF/ICSI oocyte recipient cycles performed between January 2015 and June 2022 were examined. Total of 328 cycles resulting in either fresh or frozen-thawed embryo transfers and meeting the inclusion criteria was analysed. The inclusion criteria were donor age $\leq$35 years, endometrial thickness $\geq$ 6 mm and a normal endometrial cavity on aqua scan. We excluded cycles with donor sperm or PGT-A.

Participants/materials, setting, methods: The couples who used donor oocytes because of diminished ovarian reserve, premature ovarian insufficiency, recurrent implantation failure with autologous oocytes or hereditary disease participated. Paternal and recipient ages were grouped according to previous literature to allow for comparability. The primary outcome was the live birth rate and secondary outcomes were clinical pregnancy and miscarriage rates. Simple and multivariate logistic regression analyses were performed.

Main results and the role of chance: The median recipient and paternal ages were 42 years (interquartile range [IQR] 19–50) and 42 years (IQR 19–76), respectively. The mean age of the donors was 26 years (IQR 18-35).

55.5% [N = 182] of the cycles corresponded to fresh embryo transfers and 44.5% [N = 146] to frozen embryo transfers. Indications for using donor oocytes were diminished ovarian reserve 54.39%, premature ovarian insufficiency 5.7%, recurrent implantation failure with autologous oocytes 37.05% and hereditary disease 2.85%.

The overall live birth rate was 155/328 (45.7%). Live birth outcome appeared to be significantly reduced in paternal age over 46 years after adjusting for semen parameters according to WHO 2010 criteria and for recipient age, with an OR 1.5 (95%,0.85 to 1.98, $p < 0.002$). Clinical pregnancy outcome was significantly reduced in paternal age over 51 years with OR 0.62 (95%, 0.31 to 1.89, $p < 0.0001$). The overall miscarriage rate was 15/328 (4.57%) and it was not possible to perform subgroup analysis by paternal age group due to the small numbers.

When both maternal and paternal age were retained in the multivariate model, the probability of live birth decreased with paternal age over 51 years and maternal age $\geq$40 years with OR 0.88 [0.40 to 1.38 [N = 37]).

Limitations, reasons for caution: This study has some limitations. This is a retrospective study and its relatively small subgroup sizes affected the statistical analysis of miscarriage results. In addition, we did not include any effect of sperm DNA fragmentation in the analysis.

Wider implications of the findings: The overall live birth outcome was positive. Whilst the study can be used to counsel couples with increased paternal age, it should not be used to preclude patients from treatment.

[2]*Medical School- University College London- London- WC1E 6BT- UK., Medicine, London, United Kingdom*
[3]*University College Hospital London, Andrology, London, United Kingdom*
[4]*University College London, Institute for Women's Heath, London, United Kingdom*

Study question: Assess the effectiveness of treatments at a Male Endocrine Fertility Clinic, over a five-year period, through spermatogenesis rates and fertility outcomes via a patient-centred questionnaire

Summary answer: Rate of successful spermatogenesis was 68% and live birth (LB) 36%. Trend towards lower odds ratio for LB was noted, if partners reported subfertility.

What is known already: Approximately half of infertility cases are due to male factor, with up to 70% being idiopathic. The remaining 30% of male factor infertility is attributed to primary testicular or central endocrine disorders. Identifying the aetiology of male hypogonadism is important to determine treatment strategies, such as gonadotrophin therapy and surgical testicular sperm extraction (TESE). Although treatment pathways for hypogonadal men with infertility have been established over the last thirty years, the effectiveness of such pathways is diverse and data from large studies are scanty.

Study design, size, duration: A questionnaire, covering basic demographic data about both partners, as well as health conditions affecting fertility, was prospectively sent out to 168 men who had received gonadotrophins for induction of spermatogenesis between 2017 and 2021. Men presented with azoospemia or severe oligospermia (<5million/ml). Eighty-four questionnaires (50%) were completed. Medical records were reviewed, to validate participant responses, identify baseline endocrine biochemistry from the start of spermatogenesis and seminal parameters at the end of the process.

Participants/materials, setting, methods: Mean age of participants was 38 years (range 21-63). Twenty-two men had primary (26%) and the remaining 74% central hypogonadism. The questionnaire was sent via email and responses were anonymised with each participant given a unique study identification number. All statistical analysis was performed using Graph Pad Prism. All hypothesis testing was two-tailed; $p < 0.05$ was considered statistically significant.

Main results and the role of chance: 58% of men (49/84) had sperm seen in their ejaculate and 10% of men (8/84) after microTESE. Men with persistent azoospermia were more likely to have a diagnosis of primary hypogonadism (PH) and small testicular size. 28% (13/47) had partners, who conceived spontaneously and delivered healthy babies. 9% (4/47) had a live birth after ART. Only 1 of 2 men with PH seeking fertility, had a partner with

a positive pregnancy test, which resulted in a miscarriage. Age, body mass index, alcohol intake, baseline LH, FSH and testosterone were not significantly different between men with or without a live birth.

Men without a live birth trended towards having partners with subfertility (pelvic inflammatory disease, endometriosis or polycystic ovarian syndrome), though this did not reach statistically significance (Odds ratio 6.9, 95%CI: 0.8 – 59.9, p = 0.07). Also, LBR was lower for female partners above 35 years, compared to LBR for younger female partners; 35% (6/17) for couples with partners above 35 years, versus 65% (11/17) for couples with partners below 35 years. Seminal parameters were not statistically different between men with or without live births, which supports the possibility that factors other than male reproductive status affected fertility outcomes.

Limitations, reasons for caution: The 50% response rate to our questionnaire-based study means outcomes may not be representative of all patients attending our clinic and can introduce bias with differences between responders and non-responders. Furthermore, the questionnaire used was not externally validated and its data may not be representative of outcomes in other centers.

Wider implications of the findings: Our study highlighted successful spermatogenesis and comparable live birth rates to other male fertility services worldwide. It is the first to compare the clinical, biochemical and seminal characteristics between men with live births versus those without a live birth. Ensuring couples are well informed is essential to further successful outcomes.

P-046 Sperm mitochondrial DNA copy number and mitochondrial function in normozoospermic men may predict fertilization rates after intracytoplasmic sperm injection

M. Barragan[1], R. Messaritaki[2], R. Bellido[3], R. Lafuente[3], R. Vassena[1], A. Zorzano[4], M. Popovic[1]

[1]Eugin Group, Research and Development, Barcelona, Spain
[2]Democritus University of Thrace, Department of medicine, Dragana, Greece
[3]Eugin Group, Centro de Infertilidad y Reproducción Humana CIRH, Barcelona, Spain
[4]Institute for Research in Biomedicine IRB Barcelona, Departament de Bioquímica i Biomedicina Molecular- Universitat de Barcelona & Programme Coordinator- CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Barcelona, Spain

Study question: Do sperm mitochondrial DNA copy number (mtDNAcn) and mitochondrial function correlate with fertilization rates after intracytoplasmic sperm injection (ICSI)?

Summary answer: We reveal a negative correlation between sperm mtDNAcn and fertilization rates after ICSI, while higher mitochondrial function corresponded to an increase in sperm fertilization capacity.

What is known already: Over 40% of male-factor infertility is of unknown origin (unexplained and idiopathic in nature). As current diagnoses remain largely descriptive, the identification of markers predicting the fertilization capacity of sperm will hold the key towards improved treatment. Mitochondria are fundamental for supporting spermatogenesis and fertilization. A recent study showed that altered levels of sperm mitochondrial proteins led to oocyte-activation deficiency, resulting in fertilization failure after ICSI. Poor semen parameters have also been linked to high mtDNAcn, however the relationship between mtDNAcn in sperm and oocyte-activation capacity remains unexplored. Further characterization may uncover prognostic markers associated with sperm-related fertilization failure.

Study design, size, duration: Twenty normozoospermic semen samples were included in the study. These were obtained from oocyte donation ICSI cycles, performed between March 2021 and November 2022. Both fresh and cryopreserved sperm samples were analysed. Five million sperm were collected from the fresh ejaculate for genomic DNA (gDNA) isolation and mtDNAcn quantification, while the remainder of the sample was used for mitochondrial functional analysis. These analyses were also performed on washed samples, cryopreserved after swim-up.

Participants/materials, setting, methods: Mean paternal age and BMI were 40 ± 5.8 years and 25 ± 2.3 kg/m^2, respectively. We evaluated mtDNAcn using qPCR, by assessing the ratio of mitochondrial-to-nuclear genes (NT-ND4/B2M). For our functional studies, we quantified mitochondrial membrane potential (MMP) in individual spermatozoa by JC-1 staining and flow cytometry. Flow cytometry analysis was performed on ≥ 10 million sperm treated with a mitochondrial uncoupler for 15 minutes (1 μM trifluoromethoxy-carbonylcyanide-phenylhydrazone, FCCP) and controls. Spearman correlation was applied.

Main results and the role of chance: We observed variable fertilization rates in our cohort (69.0 ± 24.9%). One sperm sample resulted in total fertilization failure (TFF) after ICSI and was analyzed independently. In fresh samples, mtDNAcn (5.8 AU ± 2.61) correlated negatively with progressive motility (rs = -0.65) and fertilization rate (rs = -0.32). Notably, the sample resulting in TFF presented with the highest mtDNAcn value (13.9 AU ± 2.77). Flow cytometry analysis revealed two distinct sperm populations, corresponding to motile and immotile sperm. While immotile sperm presented with low or undetectable JC-1 aggregates (red signal), motile sperm showed different levels of MMP (ratio INTred/INTgreen) (2.3 AU ± 1.83). In motile sperm, our results revealed a positive correlation between MMP and fertilization rate (rs = 0.59). As with raw semen, we observed a negative association between MMP and mtDNAcn in motile sperm (rs = -0.53).

Limitations, reasons for caution: Cryopreservation is known to affect sperm motility and active mitochondria in sperm, however its effect on MMP intensity remains to be established. Our limited sample size warrants careful interpretation.

Wider implications of the findings: Our findings suggest a negative correlation between sperm mtDNAcn and fertilization rates after ICSI, while fertilization capacity improved with increasing MMP. Sperm mtDNAcn and MMP may have prognostic value for male fertility and ICSI outcomes. Further validation may deliver clinically useful markers, aiding infertility diagnosis, treatment and counselling.

P-048 Vitrification of human semen impairs the mobility of spermatozoa when compared to the conventional slow-freezing

T. Pungert[1], R. Podgrajsek[2], M. Stimpfel[3], B. Rugelj[4], S. Drobnic[4], H. Ban-Frangez[4]

[1]University of Ljubljana, Biotechnical Faculcy, Ljubljana, Slovenia
[2]University Medical Centre Ljubljana, 1Division of Obstetrics and Gynaecology, Ljubljana, Slovenia
[3]University Medical Centre Ljubljana, Division of Obstetrics and Gynaecology, Ljubljana, Slovenia
[4]University Medical Centre Ljubljana, Department of Human Reproduction- Division of Obstetrics and Gynaecology, Ljubljana, Slovenia

Study question: Does vitrification provide a better method for human sperm cryopreservation than slow freezing in terms of survival, mobility, maturity, and DNA fragmentation?

Summary answer: Vitrification of human semen yields similar outcome as slow-freezing considering survival, mobility, DNA fragmentation, and maturity but the mobility after thawing is lower.

What is known already: Slow freezing is the most common technique for cryopreservation of human sperm. Unfortunately, many sperm cells die during the process or lose their mobility and are thereafter unable of fertilization. Meanwhile, vitrification of animal sperm showed good outcomes in terms of sperm survival and motility while being easier to perform than slow freezing. So far, many studies focused on survival and mobility of human sperm after vitrification compared to slow freezing, with results still not unified. They also neglected the importance of sperm maturity and DNA fragmentation caused by the process. DNA damage can affect embryo development or cause abortion.

Study design, size, duration: The study was performed from March January to July 2022. It included 69 male participants who underwent a

diagnostic spermiogram at the Division of gynaecology and obstetrics of University Medical Centre Ljubljana. All participants gave written consent of using the remaining of sample, after performing the spermiogram, for our study. Sperm samples were divided in three aliquots, one saved as native sample, one intended for vitrification, and one intended for slow freezing.

Participants/materials, setting, methods: Participants in the study had normal sperm quality parameters according to 5th edition of WHO manual. Slow freezing was performed using Sperm Freezing medium (Origio). For vitrification sperm was diluted in solution consisting of Sperm preparation medium (Origio), sucrose, and HSA in 1:1 (v/v) ratio, incubated for five minutes and then vitrified by adding 30 microliter droplets directly into liquid nitrogen. After thawing sperm survival, mobility, maturity, and DNA fragmentation were assessed.

Main results and the role of chance: The data are presented as mean values (± standard deviation) when normally distributed and as medians (IQR) when not normally distributed. The patient's age was 35.0 ± 5.1 years. In native sperm sample, sperm concentration was 69.6 ± 59.0x106 cells per millilitre and total motility was assessed to be 60.0% (50.0%-70.0%). After thawing we noticed significantly lower mobility ($p < 0.001$), while also the mobility was significantly lower after vitrification when compared to slow-freezing (17.6% (12.4%-25.3%) and 14.5% (9.0%-22.6%), $p = 0.007$). Interestingly, there was no difference in survival after thawing the samples (20.5 ± 10.7 % after slow freezing and 23.7 ± 13.7 % after vitrification). Also there was no difference in maturity of sperm when checked with protamine staining (native vs. slow-freezing vs. vitrification; 53.6 ± 15.2 % vs. 53.9 ± 16.0 % vs. 52.4 ± 15.2 %, $p = 0.905$) and also when checked with hyaluronan binding assay (78.0% (67.5%-82.4%) vs. 79.4% (71.7%-82.95%) vs. 75.3% (67.5%-81.1%), $p = 0.607$) . While sperm maturity was not affected with cryopreservation, DNA fragmentation was significantly higher after cryopreservation (native vs. slow-freezing vs. vitrification; 19.7 ± 9.5%, vs. 24.7 ± 11.6 vs. 27.1 ± 15. %, $p = 0.049$).

Limitations, reasons for caution: We believe our study would be better by obtaining higher number of participants and by being performed over longer time period. We would also like to further optimise vitrification protocol. More knowledge is also needed in poor sperm samples, since we only included sperm samples of good quality.

Wider implications of the findings: We believe our finding are of great importance for the field of andrology. Our results show vitrification of human sperm can be comparable to slow freezing in most of parameters analysed, but lower mobility after vitrification is reason for caution.

P-049 Verteporfin suppresses cell proliferation, survival and migration of TCam-2 Human Seminoma Cells via inhibits the YAP-TEAD complex

T. Önel[1], E. Yıldırım[2], A. Yaba[2]

[1]*Yeditepe University Faculty of Medicine, Histology and Embryology, İstanbul, Turkey*
[2]*Yeditepe University Faculty of Medicine, Histology and Embryology, Istanbul, Turkey*

Study question: Does verteporfin administration effect on proliferation, survival and migration of TCam-2 human seminoma cells?

Summary answer: Verteporfin may be a promising anticancer agent for TCam-2 human seminoma cells via inhibition of cell viability, proliferation, migration and stimulation of apoptosis.

What is known already: Seminoma is germ cell tumor of the testis and TCam-2 cells is the first seminoma-derived cell line that retains many of the characteristic traits of seminoma. The Hippo signalling is a evolutionarily highly conserved pathway that controls organ size, tissue homeostasis, and cancer development. In mammals, the Hippo pathway consists of the serine/threonine kinases Mammalian Sterile 20-protein Kinase 1 and 2 (MST1/2), Large Tumor Suppressor Homologues 1 and 2 (LATS1/2), Yes-Associated Protein (YAP), and its transcriptional cofactor TAZ. *Verteporfin* inhibits YAP–TEAD complex, blocking cell proliferation and survival.

Study design, size, duration: TCam-2 cells were treated with different concentrations of verteporfin (1, 5, 10, 20 and 40 μM) for 24, 48 and 72 hours (h).

Participants/materials, setting, methods: TCam-2 cells were treated with verteporfin at different doses and incubation times. Afterwards, protein expression of Hippo pathway proteins was determined by western blot, mRNA levels were analyzed by qRT-PCR and protein localizations were evaluated by immunoflourescence staining. Cell migration was determinated with wound-healing scratch assay; cell viability, early-late apoptosis and necrosis rates were evaluated by flow cytometry.

Main results and the role of chance: We detected that 40 μM verteporfin decreased LATS1/2 and p-LATS1/2 protein expression after 48h and 72h treatment ($p < 0.05$, $^{**}p<0.01$). MST1/2 and p-MST1/2 was significantly decreased in groups treated with 20 and 40 μM verteporfin after 48 and 72 h of treatment ($p < 0.05$, $^{****}p<0.0001$). YAP expression decreased at 5, 20 and 40 μM verteporfin treatment after 48h and all verteporfin concentrations after 72h ($^{**}p<0.01$, $^{***}p<0.001$, $^{****}p<0.0001$). p-YAP expression significantly decreased at all verteporfin concentrations after 48h and only at 40 μM concentrations after 72h ($^{**}p<0.01$). TEAD4 expression decreased at all verteporfin concentrations after 48 and 72h ($^{****}p<0.0001$). After 48 and 72h of verteporfin treatment, no significant difference was observed in the expression of the *MST1, MST2, LATS1, LATS2* and *YAP1* mRNA levels in TCam-2 cells, while *TEAD4* mRNA expression level was significantly decreased at 20 and 40 μM compared to control ($^{**}p<0.01$, $^{***}p<0.001$). We also showed that Hippo signaling pathway proteins localized in the cell nucleus especially YAP1 and TEAD4, were translocated to cytoplasm depending on the increasing dose of verteporfin in TCam-2 cells. Verteporfin decreased cell proliferation ($^{****}p<0.0001$), migration and cell viability ($^{****}p<0.0001$), as well as increased the early-late apoptosis ($^{**}p<0.01$, $^{***}p<0.001$, $^{****}p<0.0001$) in TCam-2 human seminoma cells dose-dependent manner.

Limitations, reasons for caution: The TCam-2 cell line was gifted by Prof. Dr. Hubert Schorle (Department of Developmental Pathology and Institute of Molecular Diagnostic Pathology, Faculty of Medicine, Germany, Bonn) to our laboratory. There is no limitation in the scope of the study.

Wider implications of the findings: We determined for the first time the effect of verteporfin treatment on the protein expression and mRNA levels of Hippo signaling pathway in TCam-2 human seminoma cells. We suggested that Hippo pathway and verteporfin relationship may be a therapeutic target for seminoma by affecting cell proliferation, survival, migration and apoptosis.

P-050 Using a second sample of ejaculate for IVF treatment

S. Lahav-Baratz[1], I. Blais[1], M. Koifman[1], A. Anat[1], N. Stein[1], Z. Wiener-Megnazi[1,2], G. Younes[1,2], G. Oron[1,2]

[1]*Lady Davis Carmel Medical Center- Haifa- Israel, Obs/Gyn Department IVF Unit-, Haifa, Israel*
[2]*Technion-Israel Institute of Technology- Haifa- Israel, Ruth and Bruce Rappaport Faculty of Medicine-, Haifa, Israel*

Study question: Is it beneficial to use the second sample of ejaculate collected within 2 hours from the previous sample to fertilize the oocytes in IVF treatments?

Summary answer: A significantly higher clinical pregnancy rate was achieved using the second sample of ejaculate.

What is known already: The WHO recommends abstinence of 2 to 7 days prior to semen collection for standard evaluation. Although semen volume and sperm concentration may increase with prolonged abstinence, such abstinence may have a negative impact on sperm motility and viability. Previous studies have shown that a second ejaculate sample following a short period of abstinence exhibited improved sperm concentration, progressive motility, vitality, and decreased DNA fragmentation. It was suggested that a second ejaculate collected within 1 h might be preferable for ART procedures.

To the best of our knowledge it has not yet been clinically implemented in routine IVF treatment cycles.

Study design, size, duration: A retrospective study of couples treated at our IVF unit between Dec 2020 and Dec 2022. All male partners were asked to give a second sample of ejaculate within 2-3 hours after the first. In all cases we used the second sample for fertilization whether it was better or worse than the first one.

Participants/materials, setting, methods: The study included 422 male partners of couples treated for IVF. Patients were divided into 2 groups. Group 1- 223 male partners that provided a second sample of ejaculate and Group 2- 199 patients unwilling to be detained that refused to provide an additional sample. Sperm count, motility percentile and sperm volume were recorded for each sample of ejaculate. Fertilization, cleavage, positive beta-hCG and clinical pregnancy rates were adjusted according to maternal and paternal age.

Main results and the role of chance: Of the 223 samples in Group 1 the second sample showed improved sperm quality in 123 samples, identical sperm parameters in 31samples and inferior sperm quality in 69 samples compared with the first sample. Regardless of sperm quality, only the second sample was used in all Group 1 participants. Demographic characteristics such as maternal age, cause of infertility, semen concentration and motility were similar in both groups. Paternal age was higher in Group 2 compared with Group 1 (37.2 ± 7.0 and 35.2 ± 6.3, $p = 0.002$ respectively). Clinical pregnancy rates were 36.9% in Group 1 and 21.8% in Group 2 ($p < 0.003$). Higher clinical pregnancy rates using the second sample remained after adjustment for maternal and paternal age OR = 1.92; 95% (1.15-3.19) and even when the second sperm sample was inferior in quality compared with the first.

Limitations, reasons for caution: The study limitation stems from the retrospective nature of the study and the fact that the groups might have a selection bias we were unaware of.

Wider implications of the findings: These findings suggest that it may be beneficial to routinely ask male partners, among couples undergoing IVF, for a second ejaculate 2-3 hours following the first. Further studies showing higher clinical pregnancy rates following the use of the second ejaculate for fertilization are needed to validate these findings.

P-051 Male cancer patient sperm cryopreservation for fertility preservation: 11-year multicenter experience: 16 regions of the mainland China national sperm

X. Liu[1], W. Qiling[2], L. Fuping[1], Z. Xinzong[2]

[1]*West China Second University Hospital- Sichuan University, Human Sperm Bank-Key Laboratory of Birth Defects and Related Diseases of Women and Children of Ministry of Education, chengdu, China*
[2]*Guangdong Provincial Fertility Hospital, NHC Key Laboratory of Male Reproduction and Genetics Guangdong Provincial Reproductive Science Institute, Guangzhou, China*

Study question: What is the current status of fertility preservation (FP) of male cancer utilization, efficacy and safety in China and what national trends could be observed?

Summary answer: In this national report on FP status of male cancer over a 11-year period, data on population and trends, region development of FP are analyzed.

What is known already: Cryopreservation of sperm, the current standard option to preserve male patient's fertility, is very advantageous for men suffering from cancer. Unfortunately, the data on population and trends, region development of fertility preservation (FP)of male cancer in mainland China is scarce.

Study design, size, duration: A multicenter retrospective study of male cancer patients who performed sperm cryopreservation from 16 regions of a national network of sperm banks over a 11-year period from 2010 to 2020. A total of 2270 men with cancer were referred to 16 human sperm banks for fertility preservation.

Participants/materials, setting, methods: This national survey was conducted through 16 provincial administrative sectors to sperm cryopreservation for Chinese male cancer. Sperm cryopreservation for male cancer is conducted in 16 human sperm banks, which done well in Sperm cryopreservation for male cancer. Cancer diagnoses were classified according to types, as Testicular tumors, Lymphomas, Leukemia, Colorectal tumors, Nasopharyngeal carcinomas, Sarcomas, Brain tumors, Extragonadal germ cell tumors, and with other cancers grouped together.

Main results and the role of chance: The number of male cancer patients with sperm cryopreservation showed an overall upward trend. Statistically significant mean yearly increases were observed for three most frequent types of cancer (testicular cancers, lymphoma, leukemia). The development of male cancer FP in the eastern, central, and western regions of Chinese mainland displayed imbalance. There are seven tumor types for sperm preservation in the top incidence ten tumor types, including lymphoma, leukemia, nasopharyngeal carcinoma, sarcoma, thyroid cancer and brain tumor. Moreover, nasopharyngeal carcinoma is a high incidence rate in China, which is related to high sperm preservation rate, different from others countries. The most percentage of males receiving sperm cryopreservation in the testicular cancers (15-39 years old) of China in 2020 was 5.55%, 1.29% in the lymphoma and 0.39% in the Leukemia. According to type of cancer, a statistically significant lower pre-sperm density, total sperm output and post-sperm density was observed in Testicular cancers. It's worth noting that the prevalence of azoospermia 22.2 % in Leukemia patients. Disposition of cryopreserved sperm categories included continued storage (47.2%), discarded (9%), death (0.9%), and use (3.7%). Up to 2020, 70 patients (3.7%) who underwent assisted reproductive technology (ART) used their cryopreserved semen.

Limitations, reasons for caution: The limitations of our study are the inability to follow-up couples who were naturally conceived. Another limitation is that not all clinical outcomes have been gated.

Wider implications of the findings: This study provides the most comprehensive national statistical census and review of fertility preservation in men cancer patients trends, quantity and cancer types. Our findings regarding patients' characteristics and analysis of semen parameters and sperm usage rate.

Trial registration number: not applicable

Abstract citation ID: dead093.417

P-052 A novel variant in CFAP69 gene causes morphological abnormalities of human sperm flagella with good ART outcomes

X. Tang[1], T. Lin[1], G. Huang[1], S. Long[1], J. Ma[1], H. Yu[1], X. Wang[1], L. Wan[2], J. Yang[2]

[2]*Chongqing Population and Family Planning Science and Technology Research Institute, Chongqing Population and Family Planning Science and Technology Research Institute, chongqing, China*

Study question: Is there any novel variant in *CFAP69* gene related to multiple morphological abnormalities of sperm flagella (MMAF) in humans?

Summary answer: We identified a loss-of-function variant of *CFAP69* in a Chinese man with MMAF and intracytoplasmic sperm injection (ICSI) is favorable for the affected couple.

What is known already: MMAF is a specific type of asthenoteratozoospermia characterized by immotile and malformed spermatozoa. Genetic defects are the major cause of MMAF, and more than 20 genes have been related to approximately 70% MMAF-affected cases. *CFAP69*, a cilia- and flagella-associated gene, is abundantly expressed in the testis and associated with infraglabellar transport. To date, four variants in *CFAP69* were related to four MMAF patients in the literatures, and the male *Cfap69*-knockout mice mimicked the infertility and profound flagellum morphology defects phenotype.

Study design, size, duration: A cohort of 35 infertile Chinese men with MMAF were recruited in the center for reproductive medicine from August

2019 to October 2022. Genetic testing was based on a targeted-sequencing panel of 22 MMAF-related genes. Morphological, ultrastructural, and immunostaining analyses were conducted in 2022. We also performed assisted reproductive technology (ART) with ICSI to explore the treatment strategies.

Participants/materials, setting, methods: Peripheral blood and semen samples were collected from every participant. The *CFAP69* variant was identified by genetic testing with targeted-panel sequencing of 22 MMAF-associated genes and validated through Sanger sequencing, pedigree analysis and *in silico* analysis. Papanicolaou staining, SEM, immunofluorescence, and TEM were performed to explore the effect of the variant. ICSI was carried out for the affected couples to get their own progenies.

Main results and the role of chance: We identified a novel frameshift variant in *CFAP69* (c.2061dup, p. Pro688Thrfs*5) from a MMAF-affected infertile male with low sperm motility and malformed morphology of sperm. Furthermore, immunofluorescence staining, and transmission electronic microscopy revealed that the variant induced reduction of CFAP69 expression and the aberrant ultrastructure including the absence of the central pair and disorder of the microtubule doublets in the patient's spermatozoa. Moreover, the partner of the proband was able to conceive through ICSI and birthed a healthy girl.

Limitations, reasons for caution: A limitation of this study is the low number of variants identified in *CFAP69* and the small number of *CFAP69*-mutant patients available. Additional *CFAP69* variants and cases are needed to better characterize the genetic etiology of the MMAF phenotype and to improve the management of MMAF patients with *CFAP69* variants.

Wider implications of the findings: This study extended the mutant spectrum of the *CFAP69* gene and could facilitate researchers and clinicians to understand the genetic etiology of MMAF better, thus improving counseling of infertile men with MMAF in the future.

P-053 Sperm aneuploidy and DNA integrity pre- and post-chemotherapy in men with testicular cancer

M. Quera Roldan[1], R. Picon[1], A. Pacheco[2,3], L. Sáncez[2], D. Amoros[4], N. Garrido[5], M. Esbert[1]

[1]*IVIRMA Barcelona, IVF Lab, Barcelona, Spain*
[2]*IVIRMA Madrid, Andrology Lab, Madrid, Spain*
[3]*UAX Universidad Alfonso X El Sabio, research, Madrid, Spain*
[4]*IVIRMA Barcelona, Andrology Lab, Barcelona, Spain*
[5]*IVI Foundation, Director, Valencia, Spain*

Study question: Are fragmentation levels (single-double stranded DNA breaks) or aneuploidy frequencies in sperm increased in patients with testicular cancer who recovered spermatogenesis after chemotherapy (CT)?

Summary answer: Similar levels of sperm DNA fragmentation and sperm aneuploidy frequency are found in men with testicular cancer pre- and post-chemotherapy.

What is known already: Testicular cancer is the most frequent solid tumor among young men. Therefore, the restoration of fertility and achievement of fatherhood in survivors have become important concerns. The integrity of genetic material in sperm is crucial since some paternal genes are essential for early embryo development. Although previous studies analyzed the effect of CT on sperm DNA integrity, they did not differentiate single vs. double-stranded DNA breaks. Few data are available on aneuploidy in sperm from testicular cancer survivors, so it remains to be elucidated whether cancer treatments may lead to an increased risk of aneuploidy syndromes in offspring.

Study design, size, duration: Prospective multicenter study including 31 males with a history of testicular cancer who requested semen cryopreservation between 2007-2021. All patients included underwent CT and recovered spermatogenesis once treatment ended. Post-CT samples were collected and seminal parameters, single-double stranded DNA breaks and the proportion of sperm aneuploidies were compared with one aliquot of the initial ejaculate. The project was approved by an Institutional Review Board and written informed consent for participation was obtained from each subject.

Participants/materials, setting, methods: Patient's age prior CT was 31.23yrs (IC 95%: 29.29-33.17). Mean interval time between 1st and 2nd samples was 4.53yrs (IC 95%: 3.42-5.64). TUNEL quantified overall sperm DNA fragmentation by flow cytometry analyzing at least 20,000 cells, while γH2AX staining was applied for double DNA fragmentation assessment. Sperm aneuploidies were calculated by using fluorescence in situ hybridization (FISH) probes for chromosomes 13, 18, 21, X, Y. A paired t-test was used to compare variables pre- and post-CT.

Main results and the role of chance: Similar results were found when sperm quality parameters were compared. Mean sperm concentration pre-CT was 33.03M/mL (IC 95%: 23.98-42.07) and 36.41 M/mL (IC 95%: 27.85-44.96) in post-CT ejaculates (N.S.). A comparable rate of motile spermatozoa was observed in pre-CT vs. post-CT samples [(43.81% (IC 95%: 38.42-49.19) vs. 44.73% (IC 95%: 38.95-50.51), N.S.].

Regarding TUNEL assay results, the sperm DNA fragmentation rate was 21.65% (IC 95%: 17.66-25.63) in pre-CT samples and 23.00% (IC 95%: 19.90-26.61) in post-CT samples (N.S.). Furthermore, similar results were obtained when double-stranded fragmentation levels (H2AX) were compared between pre and post-CT [10.2% (IC 95%: 6.45-13.96) vs. 12.44% (IC 95%: 8.75-16.13) N.S.]. Comparable sperm disomic proportions were found in PRE and POST-CT samples: [(Cr.13 =0.02%, Cr.18 =0.01%, Cr.21=0.30%, Cr.XY=0.84%) vs. (Cr.13 =0%, Cr.18 =0%, Cr.21=0%, Cr.XY=0.33%), N.S]. Results were also evaluated according to the time elapsed between the PRE and POST -CT samples. No significant differences were found for seminal values (sperm concentration, $p = 0.26$; motility, $p = 0.68$), overall sperm DNA fragmentation ($p = 0.68$), double-strand DNA fragmentation ($p = 0.90$) and the frequency of sperm disomies (Cr. 13 $p = 0.79$, Cr.18 $p = 0.46$, Cr. 21 $p = 0.85$, Cr.XY $p = 0.05$).

Limitations, reasons for caution: The main limitations of the present study are that we only recruited patients who recovered spermatogenesis and that our data evaluated a long-term effect of CT.

Wider implications of the findings: All men wishing to have their own children after gonadotoxic treatment should receive adequate counseling about the side effects of the therapy. Based on our results on sperm DNA integrity and euploidy, patients who recovered spermatogenesis should not be advised to use samples that were preserved before undergoing CT.

P-054 Significant differences of micro RNA expression pattern in extracellular vesicles between fertile and infertile individuals: new markers of male reproductive status?

L. Sánchez[1], A. Alvarez-Barrientos[2], J.A. García-Velasco[3], A. Requena[3], S. Rubio[1], A. Pacheco Castro[1]

[1]*IVI Madrid, Andrology, Madrid, Spain*
[2]*Universidad de Badajoz, Facility for Bioscience Applied Techniques, Badajoz, Spain*
[3]*IVI Madrid, Gynecology, Madrid, Spain*

Study question: Is the miRNAs cargo of the extracellular vesicles (EVs) present in seminal plasma different between healthy semen donors and infertile patients?

Summary answer: There are significant differences in the miRNAs expression patterns in the load of seminal EVs between infertile patients and healthy semen donors

What is known already: Extracellular vesicles (EVs) present in seminal plasma contain a wide range of different proteins, lipids and nucleic acids, such as microRNA. These microRNA can execute their action by regulating gene expression of target cells triggering an important role in different reproductive processes. It is well stablished in different pathologies that the EVs cargo is representative for the functional status of the producer cell. In this sense, the alteration in microRNAs expression patterns in seminal plasma has been associated with spermatogenic impairments, subfertility and

azoospermia, indicating that microRNAs in seminal EVs could work as biomarkers of the male fertility status

Study design, size, duration: This prospective study, performed between March 2021 to December 2022, included 30 semen samples from infertile males seeking infertility treatment (study group), and 7 semen samples from healthy semen donors (control group) from our donor semen bank. All the semen samples from patients showed abnormal seminal parameters (oligo- and/or asthenozoospermia). Men under drug treatment and/or with infectious or chronic diseases were excluded from the study

Participants/materials, setting, methods: After conventional semen analysis, EVs were isolated from seminal plasma by ultracentrifugation. To confirm EVs isolation, an aliquot of each sample was used for nanoparticle tracking analysis (NTA). Then, microRNAs from EVs were extracted and miRNAseq was performed. Raw data were standardized using counts per millions and ANOVA was performed to assess differences in the miRNAs expression between groups.Target genes were annotated using miRTarBase and functional enrichment analysis was performed by MIENTURNET and GeneCards

Main results and the role of chance: The presence of EVs after ultracentrifugation of seminal plasma was confirmed by NTA, showing a range size within 40-140 nm. miRNAseq generated reads for 914 annotated miRNAs and significant differences in the expression of 17 of them were found between patient and control samples. These miRNAs target a total of 1310 genes and functional enrichment analysis indicated that they participate in several processes related to cell differentiation, cell proliferation, immunomodulation, cellular adhesion and apoptosis. Specifically, patient group showed significant higher expression of some members of the hsa-let-7 family ($p < 0.001$ for let-7i-5p, let-7f-5p, let-7c-5p and let-7a-5p; $p < 0.05$ for let-7b-5p), which are implicated in adaptative immune system activation and differentiation by gene modulation. Results also found significant ($p < 0.01$) higher expression in patient group of hsa-miR-92a-3p, hsa-miR-200c-3p and hsa-miR-888-5p, which target genes are related to apoptotic processes. Finally, patient group showed significant ($p < 0.001$) lower expression of hsa-miR-320b and miR-320a-3p, which interact with transcription factor sequences (DLX5, MYC) implicated in cell proliferation and differentiation; and also lower expression in hsa-miR-423-5p ($p < 0.01$) and miR-423-3p ($p < 0.05$) that interact with the sequence of transcription factors as p21, a regulator of cell cycle progression at G1, and with RNA-binding proteins involved in ribosome assembly.

Limitations, reasons for caution: This study included males with dissimilar seminal disorders (astheno, oligo, and teratozoospermia). Therefore, further studies are needed lowering the heterogeneity of the study group. At present, no data about reproductive outcome is available

Wider implications of the findings: This work suggests that the significant differences found in the expression pattern in microRNAs in seminal EVs between infertile and fertile men may be related with gene modulation in the reproductive processes and could be used as novel biomarkers of male fertility status.

P-055 Four decades of sperm donation: Motivation and attitudes among donors

E. Lassen[1], U. Schiøler Kesmodel[2], B. Bay[3], A.B. Skytte[1]

[1]*Cryos International Sperm & Egg bank, Scientific, Aarhus C, Denmark*
[2]*The Fertility Unit, Department of Obstetrics and Gynaecology- Aalborg University Hospital, Aalborg, Denmark*
[3]*Klinik Bay & Maigaard, Fertility Clinic, Aarhus, Denmark*

Study question: How has the attitudes and motivation towards donation among sperm donors developed through the years from 1992, 2002, and 2012 to 2022?

Summary answer: Altruism and economic compensation remain the primary motivations, but there are significant changes in responses for certain life and attitude-questions from current to previous years.

What is known already: The growing application of medically-assisted reproduction (MAR) has made treatment with donor sperm commonplace, and in recent years more people have been seeking pregnancy using donor sperm. With the global shortage of sperm donors, it is important to seek the opinion of the donor population on the perspectives of anonymity, motivations, information-sharing, and feelings towards the donor-conceived children, as well as the psychological factors related to being a donor. Previous studies have shown that altruism is the primary motivation and changing aspects of the donor population is of interest to all who seek to maintain the application of sperm donation.

Study design, size, duration: The study was based on the same questionnaire from the three preceding decades with a few updated modifications in the 2022-setup. Active sperm donors from the Danish sperm bank Cryos International were invited by email to participate in the study in the period June 9th to July 1st 2022. This is one of the largest studies of its kind to seek the opinion of sperm donors.

Participants/materials, setting, methods: Results from 173 donors were compared with previous answers from donors in the same sperm bank: 1992 ($n = 39$), 2002 ($n = 58$), and 2012 ($n = 91$). In 2012 and 2022, donors could choose between being ID-release (formerly known as non-anonymous) and non-ID-release (anonymous). Anonymized answers provided from the questionnaires were analyzed statistically to compare ID-groups and investigate changes in responses from previous surveys with the use of Chi-Squared tests and logistic regression.

Main results and the role of chance: There was a significant increase in the proportion of donors being ID-release from 29% in 2012 to 54% in 2022. The altruistic motivation of helping childless people was the most important factor to both ID-release donors and non-ID-release donors. Still, economic compensation was an invariable term of condition. In general in 2022, donors were willing to donate sperm to same-sex couples (80%) and single women (68%), and 55% were positive towards donation to transgender males. Logistic regression showed that ID-release donors were more likely to want information about donor offspring (OR = 1.80, [95% CI 1.02, 3.16]), while there was no association with having a partner. Also, a positive association between ID-release status and intending to inform current or future children about their sperm donation (OR = 1.73, 95% CI 1.10, 6.85) was observed. Having a partner was not significantly associated with the chance of donors wanting to inform current or future children about donations (OR = 0.65, 95% CI 0.90, 1.05). The findings of this study presented evidence that the donor population was not homogeneous in relation to several aspects of donation and had diverse opinions towards mutual information sharing.

Limitations, reasons for caution: The number of participants increased from 39 in 1992 to 173 in 2022. In 1992, donors who were not yet approved for donation were included, unlike the following years. All donors were anonymous in 1992 and 2002 due to legislation. Only in 2012 and 2022, donors could differentiate between ID-types.

Wider implications of the findings: The questionnaire clearly shows that the needs and attitudes of donors have developed across years. Different attitudes between ID-release and non-ID-release donors suggest that donor profiles fit people with different requirements. It is advisable to continually update provided services to fit the donors' needs and opinions concerning mutual information.

P-056 Oxidative stress and human semen quality: new results for diagnostic process of male infertility

G. Traini[1], L. Tamburrino[2], L. Vignozzi[2], E. Baldi[3], S. Marchiani[1]

[1]*University of Florence- Florence- Italy., Dept. of Experimental Clinical and Biomedical Sciences "Mario Serio"-, Florence- Italy., Italy*
[2]*Andrology- Women's Endocrinology and Gender Incongruence Unit- Careggi University Hospital-, Andrology, Florence- Italy., Italy*
[3]*University of Florence- Florence- Italy., Dept. of Experimental and Clinical Medicine- University of Florence- Florence., Florence- Italy., Italy*

Study question: Is oxidative stress (OS) evaluated in human spermatozoa a predictive marker of better semen quality?

Summary answer: CellROX®Orange is a new fluorescent probe able to detect Reactive Oxygen Species (ROS) identifying a viable oxidized sperm fraction related to a better sperm performance.

What is known already: OS, defined as an unbalance between ROS production and antioxidant defences, is considered one of the causes of male infertility. OS evaluation in spermatozoa represents an important goal of research in this field because this parameter could be helpful to predict sperm fertilization ability to improve Assisted Reproductive Technology outcomes. By using different probes and methods for OS evaluation in spermatozoa or in semen, several studies were performed demonstrating a negative role of ROS on sperm functions. Such studies were not conclusive for the small number of included subjects, the high variability in the cohorts and the lack of validation.

Study design, size, duration: An observational study was conducted on 121 semen samples from patients undergoing routine semen analysis for couple infertility in the Andrology Laboratory of Careggi University Hospital of Florence from September 2021 to March 2022. Washed and Swim-up selected spermatozoa were incubated with two fluorescent probes, CellROX® Orange and Dihydroethidium (DHE), and revealed by flow cytometry.

Participants/materials, setting, methods: After routine semen analysis, the percentage of oxidized spermatozoa was evaluated with CellROX® Orange and DHE, and then correlated with standard semen parameters and sperm DNA fragmentation (sDF, evaluated by TUNEL/PI). Sperm kinematic parameters and hyperactivated motility were also assessed by C.A.S.A. system. Furthermore, CellROX® Orange positivity and phosphatidylserine membrane exposure (determined by Annexin V staining) or Caspase 3 and 7 activities (measured by FLICA™) were concomitantly evaluated.

Main results and the role of chance: We demonstrated that CellROX® Orange is able to detect hydrogen peroxide only in viable spermatozoa and the percentage of CellROX® Orange positive spermatozoa were positively associated with semen quality and negatively with sDF. To confirm these results, we performed the same experiments by using DHE, another probe which reveals hydrogen peroxide and superoxide anion in both viable and unviable cells. Similarly to CellROX® Orange, a positive correlation with semen quality and a negative one with sDF were found in viable spermatozoa. Conversely, in unviable spermatozoa, opposite associations were observed. These results indicate that oxidative status revealed by the two probes is related to a better sperm quality. To further investigate this possibility, we double labelled spermatozoa with CellROX® Orange and Annexin V (a marker of early signs of apoptosis) as well as with CellROX® Orange and FLICA™ (that detects caspase activity, a late sign of apoptosis). We found that CellROX® Orange mostly identifies spermatozoa without apoptotic features. Furthermore, we evaluated CellROX® Orange positivity in Swim-up selected spermatozoa, finding significantly higher levels in these samples respect to unselected samples, demonstrating once again that this probe identifies spermatozoa with better quality.

Limitations, reasons for caution: Our results indicate that within the viable oxidized spermatozoa there are cells with physiological and non-physiological intracellular ROS levels, however, they do not explain at what levels ROS cease to be functional and become deleterious for spermatozoa.

Wider implications of the findings: ROS evaluation in viable spermatozoa with the commercially available probes CellROX® Orange and DHE, allows the identification of the oxidized sperm fraction related to a sperm better performance. Therefore, the two probes may be useful to determine such fraction, likely improving the diagnostic process of male infertility.

P-057 Does sperm cryopreservation affect the clinical outcome? A retrospective study in an oocyte donation program

K. Pantopikou[1], C. Oraiopoulou[1], A. Papatheodorou[1], P. Drakopoulos[1], N. Christoforidis[1], A. Chatsiparasidou[1]

[1]*EMBRYOLAB IVF Clinic, IVF Lab, Thessaloniki, Greece*

Study question: Does sperm cryopreservation have a negative impact on pregnancy and live birth rate (LBR)?

Summary answer: The use of frozen sperm does not affect pregnancy rates and LBR significantly compared to fresh sperm.

What is known already: The use of frozen sperm, especially in oocyte donation cycles, is a common strategy in organizing a couple's treatment. By now, contradictory data has been published concerning the impact of fresh sperm versus frozen on pregnancy and LBR. There is data indicating reduction of the LBR with the use of frozen sperm in a donation program, while in other studies no significant difference between fresh and frozen sperm was observed in the LBR.

Study design, size, duration: This is a retrospective cohort study conducted in Embryolab Fertility Clinic, Greece, from January 2019 to March 2020. Only oocyte donation cycles were included in the study. On the day of donor's oocyte retrieval ICSI was performed, either with fresh (group A) or frozen sperm (group B)All embryos were cultured to blastocyst stage, assessed for their development, vitrified and two were transferred post warming on a subsequent HRT cycle.

Participants/materials, setting, methods: For the present study, 135 cases were analyzed: in 28 cases fresh sperm was used, while frozen sperm was used in 107 cases[pd1] . The mean men's age was 44.4 years, while all oocyte-donors were below 35 years old. The main outcome measure was LBR, while fertilization rate, blastulation rate as well as positive β-HCG were also analyzed. All patients with uterine factor, severe male factor or surgically obtained sperm were excluded from the study.

Main results and the role of chance: There was no significant difference between LBR of fresh vs frozen sperm (53.57% ± 50.78 vs 50.47% ± 50.23, p=0.086). Although positive β-CG reached a higher percentage in fresh sperm samples, there was no significant difference between two groups (85.71% ± 35.63 in fresh vs 77.78% ± 41.76 in frozen sperm, p=0.857). Similarly, both blastulation rate (68.93% ± 25.22 in fresh vs 67.97% ± 28.72 in frozen sperm, p=0.873) and fertilization rate (85.36% ± 16.92 in fresh vs 83.27% ± 17.01 in frozen sperm, p=0.565) did not differ significantly between fresh and frozen sperm samples. [pd1] Regression analysis adjusting for relevant confounders (endometrial thickness the day of the embryo transfer, BMI, donor's age) showed no association between LBR and sperm type (fresh vs cryopreserved).

Limitations, reasons for caution: This is a retrospective study, including sperm samples irrespectively to quality parameters (sperm count, motility, morphology). The number of previous treatments per couple was not included in the study.

Wider implications of the findings: The outcome of the study indicates that the use of frozen sperm is a viable choice in a donation program, as it does not induce any negative effects in LBR. However, specific subgroups might benefit from fresh sperm especially when the sperm parameters are low.

P-058 Defects in phospholipase C zeta cause polyspermy and low fertilization after conventional IVF: not just ICSI failure

C. Dai[1], J. Che[1], S. Zeng[1], H. Wu[1], Y. Wu[1], J. Dai[2], D. Cheng[2], Q. Wen[3], F. Gong[2], G. Lu[2], G. Lin[2]

[1]*Hunan Normal University, School of Medicine, Changsha, China*
[2]*Reproductive and Genetic Hospital of CITIC-Xiangya, Reproductive Center, Changsha, China*
[3]*Central South University, School of Basic Medical Science, Changsha, China*

Study question: How does sperm phospholipase C zeta (PLCζ) affect fertilization in conventional *in vitro* fertilization (cIVF)?

Summary answer: Absence of PLCζ causes polyspermy, and a decline in the proportion of sperm expressing PLCζ is correlated with a low fertilization rate (FR) after cIVF.

What is known already: PLCζ is a key sperm-borne factor that triggers Ca^{2+} oscillations and the subsequent oocyte activation following gamete fusion. Mutations in *PLCZ1*, the gene encoding PLCζ, cause male infertility and intra-cytoplasmic sperm injection (ICSI) fertilization failure; and PLCζ expression and localization patterns are significantly correlated with ICSI FR. However, few studies have been published on the relationship between PLCζ and cIVF, an insemination procedure involving several key events that are bypassed in ICSI, e.g., sperm-zona binding and penetration, as well as polyspermy blocking. It is possible that sperm PLCζ may affect fertilization in a different manner from that in ICSI.

Study design, size, duration: Sixty couples who underwent cIVF treatments were recruited from the Reproductive and Genetic Hospital of CITIC-Xiangya between February 2019 and January 2022.

Participants/materials, setting, methods: We performed whole-exome sequencing in two unrelated males who exhibited infertility and polyspermy in cIVF. Immunofluorescence staining and oocyte-activation testing were employed to evaluate the effects of the candidate variants on PLCζ protein. Subsequent PLCζ analysis was performed in additional 58 males who underwent cIVF. The Pearson correlation coefficient was performed to evaluate the relationships between PLCζ and FRs. The receiver operating characteristic curve and Youden's index analysis were used to indicate the cutoff value.

Main results and the role of chance: We identified one previously reported and two novel *PLCZ1* variants in two males that were associated with male infertility and polyspermy characterized by excessive sperm–zona binding and a delay in pronuclear (PN) formation. *In vitro* functional analyses revealed that virtually all sperm from patients lacked functional PLCζ and were thus unable to evoke the physiologic pattern of Ca^{2+} oscillations. ICSI with an artificial oocyte-activation treatment successfully rescued the polyspermic phenotype and resulted in a live birth. Subsequent PLCζ analysis were performed in additional 58 males, who were allocated to three groups according to fertilization outcomes: a multiple pronuclear (MPN) group (no. of PN $\geq$ 3, MPN rate $\geq$ 50%, n = 9) and low fertilization (LF, total FR $\leq$ 30%, n = 18) and normal fertilization groups (NF, 2PN $\geq$ 50%, 1PN + MPN < 30%, n = 31). We found that the proportion of sperm that expressed PLCζ was positively correlated with both 2PN rate ($P = 0.0005$) and total FR ($P = 0.0008$) after cIVF, and that the optimal cutoff value below which males were likely to experience low FR (total FR $\leq$ 30%) after cIVF was 56.7% (area under the ROC curve, 0.705; $P = 0.0176$).

Limitations, reasons for caution: Precise mechanisms that underly the roles of PLCζ in cIVF outcomes are still uncovered. Follow-up studies with larger numbers of patients are required to validate the sensitivity, specificity, and accuracy of PLCζ as a diagnostic biomarker in cIVF outcomes.

Wider implications of the findings: Our study identified *PLCZ1* as a novel causative gene of polyspermy in humans,highlighting the potential value of PLCζ as a fertility marker for cIVF outcomes.

P-059 Sperm DNA fragmentation (SDF) after cryopreservation and sperm selection: implications for clinical pregnancies and live births after intrauterine insemination with donor sperm

T. Chimienti[1], U. Punjabi[1], I. Goovaerts[1], K. Peeters[1], J. Bouziotis[2], D. De Neubourg[1]

[1]*University Hospital of Antwerp, Centre of Reproductive Medicine, Antwerp, Belgium*
[2]*University Hospital of Antwerp, Clinical Trial Center, Antwerp, Belgium*

Study question: Can SDF assessment pre-cryopreservation, post-thaw and after post-thaw sperm selection predict clinical outcome in a heterologous intra-uterine donor insemination program (IUI)?

Summary answer: SDF increased post-cryopreservation in donor sperm and after post-thaw density gradient without affecting clinical pregnancy, live birth and miscarriage rates.

What is known already: Sperm cryopreservation is effective for preservation of male fertility and facilitates the storage of donor semen, while infectious disease screening can be completed and confirmed negative. Sperm viability and motility are the most vulnerable parameters during the freeze-thaw process. Inherent reactive oxygen species may induce SDF via oxidative stress. Controversial results are reported regarding induction of SDF after cryopreservation due to differences in cryo tolerance, methods of cryopreservation and methods used to evaluate SDF. Sperm selection post-thaw is indispensable to select a normal motile fraction for insemination. Again, results are controversial regarding influence on SDF levels after sperm selection post-thaw.

Study design, size, duration: This was a prospective, observational study. Between March 2015 and March 2019, eighteen potential sperm donors were screened via a three step plan – semen assessment, medical assessment and serological blood tests. In accordance with the Belgian legislation (2007), a sperm donor was matched to obtain a maximum of 6 pregnancies in acceptor women/couples, allowing for more than one offspring/woman or couple. A total of 106 acceptors were matched for heterologous intra-uterine insemination.

Participants/materials, setting, methods: Semen samples were collected after 2-7 days abstinence and standard semen parameters analyzed within 60 mins after ejaculation. Within the same time frame SDF test was performed using TUNEL assay both before and after cryopreservation and after a two-step discontinuous density gradient centrifugation post-thaw. Samples were cryopreserved by the conventional slow freezing method using sperm freeze solution. A yield of $\geq$ 2 M progressive spermatozoa post-thaw after selection was sufficient to contemplate IUI.

Main results and the role of chance: Mean female age at first cycle was 33.9 ± 4.1 years and donor age 28.5 ± 5.6 years. Out of 429 cycles, 100 (23.3%) resulted in clinical pregnancy. Excluding three ongoing pregnancies, we counted 75 live births (17.6% of cycles or 77.3% of pregnancies), while 21 pregnancies ended in miscarriage (4.9% of cycles or 21.6% of pregnancies) and 1 resulted in stillbirth.

Progressive motility (59.3 ± 12.5%) decreased significantly after cryopreservation (30.0 ± 13.2%; $p < 0.001$), but increased post-thaw after density gradient centrifugation (61.6 ± 16.0%; $p < 0.001$). On the contrary, SDF (12.0 ± 5.9%) increased post-cryopreservation (26.3 ± 14.5%; $p < 0.001$) and further increased after sperm selection (34.9 ± 22.1%; $p = 0.04$).

Using multilevel mixed-effects logistic regression (Odds ratio [95%CI]), we found that female age significantly influenced clinical pregnancy (0.911 [0.847-0.981]; $p = 0.01$), live birth (0.894 [0.834-0.959]; $p = 0.002$) and miscarriage rates (1.180 [1.033-1.347]; $p = 0.015$). There was no significant age-adjusted effect of SDF post-thaw after density gradient selection on clinical pregnancy (1.007 [0.994-1.021]; $p = 0.30$), live birth (1.001 [0.988-1.014]; $p = 0.84$) or miscarriage (1.021 [0.997-1.046]; $p = 0.08$). Median time-to-live birth was 4 cycles. Analyses of time-to-live birth with mixed-effects Cox models revealed no significant association with progressive motility; SDF before or after cryopreservation and after sperm selection post-thaw.

Limitations, reasons for caution: Results concern a small donor population, with high normal semen parameters and should therefore be extrapolated cautiously to subfertile men with normal and subnormal semen parameters.

Wider implications of the findings: In a donor IUI program with strict selection on conventional sperm parameters, differences in SDF before and after cryopreservation and gradient centrifugation do not change IUI outcomes, although cryopreservation and centrifugation increase SDF. Findings could be useful for the optimization of sperm freezing and selection in different assisted reproductive procedures.

[6]University Federico II, Biology Department, Napoli 80126, Italy
[7]University Federico II, Department of Agricultural Sciences, Portici 80055, Italy

Study question: The DNA spermatozoa integrity impacts on the male fertility, we aim to define if the damage status can predict the pregnancy.

Summary answer: The relation between the spermatozoa DNA damage and the pregnancy can support the doctor to recommend the couples to proceed in vivo or vitro conception

What is known already: The DNA spermatozoa is getting more and more important in the male fertility. Studies show that spermatozoa of infertile males have higher level of DNA damage than fertile males. DNA damages are often connected to poor seminal parameters such as sperm count, motility and morphology even if the 8% of males with normal seminal parameters show the same diagnosis. We are also skeptical about using the spermatozoa with damaged DNA in the ICSI, indeed there could be some consequences. The WHO suggests to evaluate the DNA damage in the routine exams.

Study design, size, duration: The aim of the study is to develop an Artificial Intelligence model that it can predict the pregnancies related on DNA quality of spermatozoa. During 2015 and 2017, we evaluated the DNA damage of 268 male after their partners had a natural pregnancy. The DNA spermatozoa damage is evaluated with p53 protein dosage so we developed a preliminary "learning model".

Participants/materials, setting, methods: It has been enrolled 356 male partners (pm) of infertile couples, divided into:

group A, 123 pm with 2-9 million spermatozoa/ejaculate (ICSI);
group B, 108 pm with 10-38 million spermatozoa/ejaculate (IUI);
group C, 125 pm with >39 million spermatozoa/ejaculate (natural conception).

p53 dosage, with ELISA method, was performed for the groups A and B preliminary to the treatment ICSI and IUI; for group C, it was performed from 10 to 30 days afterwards pregnancy (betaHCG > 400 miU/mL)

Main results and the role of chance: Group A: 29 pregnancies (23,6 %) occurred out of 123 ICSI performed.

According to our learning model:

- group A1: 42 pm (p53 < 1.65), 26 pregnancies were assumed against the 25 obtained, forecast percentage of 96.2 %.
- group A2: 81 pm (p53 > 1.66), 6 pregnancies were assumed against the 4 obtained with a forecast percentage of 66.6 %.

Group B: 16 pregnancies (14,8 %) occurred out of 108 IUI performed.

According to our learning model:

- group B1: 38 pm (p53 < 1.65), 16 pregnancies were assumed against the 14 obtained, forecast percentage of 87.5 %.
- group B2: 70 pm (p53 > 1.66), 2 pregnancies were assumed against the 2 obtained with a forecast percentage of 100.0 %.

Group C: out of 125 couples, with natural conception, 28 pregnancies (22,4 %).

According to our prediction model:

- group C1: 71 pm (p53 < 1.65), 25 pregnancies were assumed against the 24 obtained, predicted rate of 96.0 %.
- group C2: 54 pm (p53 > 1,66), 4 pregnancies were assumed against the 3 obtained with a 75,0 % forecast percentage.

The forecast is accurate (AUC 0.70).

Limitations, reasons for caution: The comparison between the control "learning model" and the expectation is not totally comparable. It is necessary to add a detailed case history of the couple to minimize other factors that may interfere with conception. For this reason, it is still necessary to be cautious to adopt this model.

Wider implications of the findings: A preventive examination, such as evaluating sperm DNA damage, could minimize in vivo and in vitro conception failures.

This "learning model" seems to have an excellent ability to predict a pregnancy. To achieve greater sensitivity, greater numbers are needed through its diffusion.

P-061 In situ microfluidics of fluidic walls: a novel deviceless and cost-effective approach for sperm selection in the same ICSI-dish

M. Ruiz - Jorro[1], J.J. Bataller-Sánchez[2], A. Barberá-Alberola[2], B. Gómez-Giménez[2], V. Moliner-Aguilar[2], C. Calatayud-Lliso[3], M. Ferrer-Buitrago[4]

[1]CREA Medicina de la Reproducción, Reproductive Andrology Department, Valencia, Spain
[2]CREA Medicina de la Reproducción, Andrology laboratory, Valencia, Spain
[3]CREA Medicina de la Reproducción, Clinical Department, Valencia, Spain
[4]CREA Medicina de la Reproducción, Research Department, Valencia, Spain

Study question: Is our novel deviceless method based on *in-situ* microfluidics a valuable strategy to select suitable sperm for ICSI?

Summary answer: The novel protocol allows selecting sperm for ICSI within 15 minutes, in the same ICSI dish and disregarding fungible supplies, centrifugation and washing steps.

What is known already: Microfluidics is an innovative operation in ART which integrates sperm guidance biomimicry during the *in vitro* sperm selection process. In contrast to other sperm preparation methods such as Wash-Swim-Up and Density- Gradients-Centrifugation, microfluidics disregards washing and centrifugation steps along the procedure. In addition, microfluidics are time-efficient methods which reduce risks associated with handling, gamete mix-up and ROS production. However, microfluidics devices are costly and likely to fail to select motile sperm in dispermic samples. With the aim of outlining the application of microfluidics in ART, we conceived a lab-on-a-chip approach for sperm selection by *in-situ handmade* microfluidics of fluidic walls.

Study design, size, duration: The microfluidics circuit conforms to Laplace and hydrostatic pressure laws and integrates the sperm guidance mechanisms of rheotaxis and boundary-following behavior. System's efficacy is based on the volume differences, the distances between microdoplets, and their arrangement. It divides into Section 1 (dispersion and seminal plasma removal) and Section 2 (sperm sorting in response to positive rheotaxis). The system was adjusted to recover at least 20 selected progressive sperm for ICSI in less than 15 minutes.

Participants/materials, setting, methods: We prepared the system on a conventional IVF polystyrene round dish (15 mm diameter) using MOPS buffer, PVP and mineral oil only. We verified the flow-driven dynamics by registering the horizontal displacement (direction) and flow velocity (μm/s) using eosin-Y and methylene blue dyes. We confirmed the removal of the seminal plasma in a PSA assay. The proof-of-concept analysis was performed using fresh semen samples from 150 patients (Caucasian; mean age: 33,53 ± 8,19).

Main results and the role of chance: Our design includes three main points to allow sperm separation: 1 (initial), 2 (rebalancing), 3 (final) with a total distance of 1,5 cm between 1 and 3. Our system assures a continuous microfluidic flow, with two opposed directions (from point 1 to point 2 and from point 3 to point 2). PSA assay showed a significant decrease in PSA levels >200000 ng/ml in the fresh sample to undeterminable levels (<0,0091 ng/ml) at point 3. To assess the utility to select a suitable number of sperm for ICSI we used sperm samples with the following characteristics: volume 3,6 (1,0-7,6) ml, concentration 68 (0,29-150) $\times 10^6$/ml, progressive motility 24 (2-41) % and morphology 6 (1-15) % normal. The minimum and maximum times for sperm recovery at point 3 were recorded at 5 and 35 minutes, respectively. Normozoospermic samples required lower recovery times compared to dispermic ($p < 0,001$), although according to the median, samples with at least 1×10^6/ml of motile sperm need less than ten minutes recovery time. Sperm parameters: concentration, motility and morphology were inversely correlated with the recovery time ($p < 0,0001$), being morphology the parameter with the lesser influence on the outcome.

Limitations, reasons for caution: The present protocol depends on a free-hand preparation. Although the use of templates and the training reduces inter and intra-operator variability, a ready-to-use surface would benefit the operability. Non-inferiority studies are required to compare our method with the currently used ones (Wash-Swim-Up or Density-Gradients-Centrifugation) before clinical implementation.

Wider implications of the findings: Our deviceless methodology streamlines sperm selection for ICSI and reduces risks along the procedure. This novel approach represents a paradigm shift in sperm preparation, since it dispenses with centrifugation, washing and plasticware. The present protocol can be implemented to the clinic in the near-term, particularly due to its simplicity.

P-062 The influence of the ejaculatory abstinence period on semen parameters from the first diagnostic sample – results from analysis of 14000 samples

P. Sokol[1], A. Racca[1], M. Ballester[1], I. Rodríguez[1], N.P. Polyzos[1]

[1]*Dexeus University Hospital, Department of Obstetrics- Gynecology and Reproductive Medicine, Barcelona, Spain*

Study question: Is ejaculatory abstinence period (EAP) associated with semen parameters in males undergoing preliminary fertility investigation?

Summary answer: Short EAP is associated with increased progressive motility (%), vitality but with reduced volume, concentration, total sperm count. No association was indentified with morphology, DNA fragmentation.

What is known already: It is known that semen parameters may present important intra-individual variations. At present, the last edition of the WHO Manual recommends ejaculatory abstinence from two to seven days for semen analysis.

Nonetheless, this period is not supported by some relevant bodies in the reproductive field guidelines that limit abstinence period to three or four days. Recently published reviews on this matter support that the relationship between the abstinence time and sperm quality is not straightforward. Therefore the aim of this study is to analyze correlation between the ejaculatory abstinence time and sperm parameters in patients having initial work-up in our clinic.

Study design, size, duration: We conducted a retrospective cross-sectional study on the diagnostic semen samples from individuals having their initial fertility investigation in the Fertility Department of a University Affiliated Hospital between the beginning of 1997 and the end of 2022. Basic semen parameters and sperm deoxyribonucleic acid (DNA) fragmentation were registered in 14067 and 784 samples respectively. Sperm morphology was analysed in 4812 samples.

Participants/materials, setting, methods: We included exclusively results from the first diagnostic semen sample from males of any age undergoing preliminary infertility work-up. All samples were produced on-site and analysed "*ad hoc*" for basic semen parameters (according to 6th Edition of WHO Manual) or/and sperm DNA fragmentation (Sperm Chromatin Dispersion test). Samples were divided according to EAP: ≤2(**A**-group); 2-7(**B**-group); >7 days (**C**-group) and compared with ANOVA. Additionally, Spearman Correlation was used to confirm correlation between EAP and sperm parameters.

Main results and the role of chance: Semen analysis was performed either completely manually (23.4%) or with the use of Computer Assisted Semen Analysis (CASA) system (76.6%) with the exception of morphology which was always assessed manually.

Overall, 661 samples were produced after ≤2 days of abstinence, 12734 after 2 to maximum 7 days and 690 after >7 days of which ones 330(50%), 6798(53%) and 336(49%) were normozoospermic, respectively. Mean male age was 39 years (SD 6.5) and EAP 4.5 days (SD 1.9).

We found the following parameters positively correlated with EAP in both normozoospermic and abnormal samples: volume (A-2.6ml; B-3.6ml; C-4ml, $p < 0.05$), concentration (A-72M/ml; B-93M/ml; C-127M/ml, $p < 0.05$), total sperm count (A-161M; B-285M; C-472M, $p < 0.05$), total motile count (A-111M; B-186M; C-270M, $p < 0.05$), straightness coefficient (STR) (A-73.1; B-75.7; C-77.8%, $p < 0.05$) and Zinc concentration (A-14277; B-17375; C-22538µg/dl, $p < 0.05$).

The following parameters were negatively correlated with EAP in both normozoospermic and abnormal samples: progressive motility (A-46; B-43.6; C-36.6%, $p < 0.05$), vitality (A-60.5; B-60.3; C-53.7%, $p < 0.05$).

We did not find any correlation with leucocytes, fructose, morphology or DNA fragmentation in unselected patients. However, in the group of abnormal samples there was a negative correlation between EAP and morphology (A-3.7; B-3.1; C-2.8%, $p < 0.05$) and DNA fragmentation, in generalized additive model (Spearman-Correlation, R^2 0.01, $p < 0.05$).

Limitations, reasons for caution: This is a cross-sectional study which demonstrates only association and does not allow establishment of a cause-effect relationship between EAP and sperm parameters. Additionally, despite significant correlation between EAP and some sperm parameters, its clinical usefulness remains unclear.

Wider implications of the findings: To our knowledge this is first study correlating EAP with semen parameters only from diagnostic semen samples produced on-site, which confirms that the abstinence time should be seriously considered when analysing ejaculates, especially when borderline results are obtained. Additionally, different clinical strategies may be considered for normo and non-normozoospermic patients.

Trial registration number: not applicable

P-063 Microfluidic technology is highly effective in selecting a sperm population with high progressive motility and low DNA fragmentation index

I. Mateizel[1], A. Racca[2], E. Aligianni[3], E. Distasi[4], I. Segers[1], D. Jankovic[1], C. Schoemans[1], K. Wouters[1], H. Tournaye[1], N. De Munck[1]

[2]*Dexeus University Hospital, Department of Reproductive Medicine, Barcelona, Spain*
[3]*University of Crete, Department of Biology, Crete, Greece*
[4]*University of Teramo, Faculty of Bioscience and Technology for Food- Agriculture and Environment, Teramo, Italy*

Study question: Which sperm preparation procedure is able to select the best population of sperm?

Summary answer: Microfluidic sperm sorting using Fertile Plus device isolates sperm with the highest motility and lowest levels of DNA fragmentation.

What is known already: The sperm selection in Medically Assisted Reproduction should lead to fully functional spermatozoa able to reach the fertilization site and allow optimal fertilization and embryo development. These abilities are dependent on specific sperm parameters such as, but not limited to, motility, morphology, Acrosome Index (AI), and DNA fragmentation Index (DFI). At present, the routine sperm selection is suboptimal, does not replicates the physiological processes observed in nature and consequently may induce sperm damage. The new Microfluidic Sperm Sorting technology allows a physiological selection of sperm. However, no comparison with other selection procedures regarding all the above-mentioned parameters was reported.

Study design, size, duration: Prospective-observational study performed at an University Hospital-IVF Centre between April-November 2022 comparing the effect of four different sperm selection procedures on various semen parameters. Fifty-two samples with minimum $20x10^6$ sperm/ml and progressive motility ≥30% were included.

Descriptive statistics reported the mean ± SD [minimum-maximum] values for each variable. Interclass correlation coefficient (ICC) was calculated for the absolute agreement in between the four different procedures, where DGC was considered the standard-of-care. An ICC-value <0.4 indicates a low agreement.

Participants/materials, setting, methods: Unused raw semen after routine diagnostic analysis were individually split in 4 fractions and processed immediately by different sperm preparation methods: 1) sperm wash (SW), 2) Density Gradient Centrifugation (DGC), 3) Magnetic Activated Cell Sorting (MACS, (Miltenyi Biotec)), and 4) Microfluidic Sperm Sorting (MSS) using Fertile Plus Device (Koek Biotechnology).

Each fraction was analyzed for progressive motility, morphology, Acrosome Index (AI) and DNA fragmentation Index (DFI; TUNEL assay protocol).

Main results and the role of chance: The mean age of the patients was 35.9 years (SD ± 6.8). The mean value of days of abstinence was 4.1 (SD ± 6.8).

Mean progressive motility rates were: 54.3 ± 10.6% [23-86%], 74.3 ± 11.8% [38-90%], 77.2 ± 12.5% [37-92%] and 88.6 ± 4.2% [73-96%] for SW, DGC, MACS, and MSS, respectively.

Mean percentages of normal morphology were: 3.3 ± 2.9% [0-13%], 4.1 ± 3.1% [0-13%], 4.2 ± 3.7% [0-18%], and 5.1 ± 3.9% [0-16%] for SW, DGC, MACS, and MSS, respectively.

Mean AI were: 8.5 ± 4.9% [1-20%], 9.7 ± 6.0% [1-30%], 8.7 ± 4.9% [0-19%], and 10.8 ± 6.8% [1-30%] for SW, DGC, MACS, and MSS, respectively.

Mean DFI were: 6.2 ± 4.6% [0.8-26.1%], 2.7 ± 3.2% [0.2-14%], 2.1 ± 4.3% [0.9-20.8%], and 0.2 ± 0.4% [0.0-2.3%] for SW, DGC, MACS, and MSS, respectively.

Values referring to ICC absolute agreement between the DGC and the other methods indicate MSS as the only procedure in strong disagreement regarding progressive motility [0.29, 95%CI (-0.2-0.58)] and DFI [0.17; 95%CI (-0.19-0.45)]. No disagreement regarding morphology and AI was observed between all techniques.

A further paired comparison confirmed the strong disagreement between MSS and MACS [0.2; 95%CI (-0.17-0.49) and 0.21; 95%CI (-0.25-0.52)] and between MSS and SW [0.06; 95%CI (-0.04-0.25) and 0.06; 95%CI (-0.15-0.28)] regarding progressive motility and DFI, respectively.

Limitations, reasons for caution: Differences in DNA-damage may have been smaller between techniques if abstinence period was shorter. Due to the design of the experiment, data on clinical outcomes are not available.

Wider implications of the findings: The selection of a population of highly motile spermatozoa with undamaged DNA from unprocessed semen is ideally performed with MSS using Fertile Plus. Question remains how these results compare with a shorter abstinence period and whether this improves the embryological outcomes in the IVF laboratory.

P-064 MicroRNAs as potential biomarkers for male infertility related to Testicular Germ Cell Tumors

C. Ferrara[1], R. Battaglia[1], A. Caponnetto[1], C. Barbagallo[1], M. Stella[1], M.E. Vento[2], P. Borzi[2], P. Scollo[2], F. Lunelio[2], D. Barbagallo[1], S. Pernagallo[3], M. Ragusa[1], C. Di Pietro[1]

[1]University of Catania, Department of Biomedical and Biotechnological Science, Catania, Italy
[2]Cannizzaro Hospital, IVF Unit, Catania, Italy
[3]DESTINA Genomica S.L., Parque Tecnológico Ciencias de la Salud PTS, Granada, Spain

Study question: Could microRNAs represent efficient biomarkers to evaluate male infertility and the tendency of develop testicular germ cell tumors (TGCTs)?

Summary answer: The up-regulation of miR-193a-5p, miR-93-5p and let-7c-5p in TGCT patients with impaired spermiogram could represent a molecular signature of male infertility related to TGCTs.

What is known already: Testicular germ cell tumors (TGCTs) are the most recurrent tumors in young men with the highest incidence between the ages of 20 and 40 years and represent more than 60% of all cancers diagnosed in this age range. Several studies have shown a correlation between TGCTs and infertility, not only because infertility could be a consequence of testicular damage due to TGCTs but also because infertility may represent a risk factor for TGCTs. Therefore, it is important to find valid biomarkers that could be used to specifically identify infertility related to an increased risk of developing TGCTs.

Study design, size, duration: From March 2021 to January 2023, we collected 44 seminal plasma samples: 17 from TGCT patients who were undergoing sperm cryopreservation prior to chemotherapy, 14 with impaired spermiogram (IS) and 3 with normal spermiogram (NS) and 27 from control patients, 16 with IS and 11 with NS, undergoing assisted fertilization techniques. We evaluated the potential role of miRNAs as non-invasive biomarkers, analyzing the differential expression of 84 miRNAs in relation to cancer, infertility and both.

Participants/materials, setting, methods: Semen samples were placed 30'/37°C, seminal plasma was purified using density-gradient centrifugation and stored at -80°C. RNA was purified by Qiagen miRNeasy Serum/Plasma Kit and analyzed by miRCURY LNA miRNA SYBR®Green PCR_SerumPlasma, 96-well plate. We applied the $2^{-\Delta\Delta CT}$ method and statistical significance was evaluated by Significance Analysis of Microarrays, screened by p-values ≤ 0.05. We performed a Pearson correlation analysis applying two-sided p-values. miRTarBASE, MIENTURNET and Cytoscape were used for bioinformatics analysis.

Main results and the role of chance: In the four comparisons, we found 9 differentially expressed microRNAs. In particular, miR-221-3p, miR-222-3p, miR-204-5p and miR-205-5p down regulation would appear to be related to infertility, regardless to the cancer. Conversely, all TGCT patients shown an up-regulation of miR-376c-3p. Interestingly, up-regulation of miR-193a-5p, miR-93-5p and let-7c-5p specifically discriminates the infertile cancer patients *vs* other categories. Moreover, these three miRNAs showed a significant positive correlation both in cancer patients with impaired spermiogram and in infertile controls. This correlation demonstrates that their expression changes in the same way in the single samples and strongly suggests their role as early biomarkers of TGCT patients with impaired spermiogram. From the KEGG pathway analysis has emerged that DE miRNAs are involved in several signaling pathway, such as MAPK, mTOR, p53, PI3K-Akt, AMPK, FoxO, JAK-STAT, Ras, Estrogen signaling pathways, as well as cell cycle and cellular senescence. Moreover, from the Diseases Ontology analysis we found than those miRNAs are involved in germ cell tumor, male reproductive organ cancer, prostate cancer, male infertility and azoospermia.

Limitations, reasons for caution: The data must be validated by single assays in higher number of samples. These experiments are currently ongoing.

Wider implications of the findings: Three of the DE miRNAs are overexpressed in TGCT with impaired spermiogram patients. Specifically, they are over-expressed in TGCT with impaired spermiogram compared to infertile controls, so they may represent specific biomarkers able to discriminate, among the young men with infertility, those with higher risk of develop testicular cancer.

P-065 A systematic review of the accuracy of laboratory semen analysis as a test of fertility

A. Holt-Kentwell[1], D. McLernon[2], M. Ntessalen[2], S. Bhattacharya[3], A. Maheshwari[1]

[1]NHS Grampian, Aberdeen Fertility Centre, Aberdeen, United Kingdom
[2]University of Aberdeen, Institute of Applied Health Sciences, Aberdeen, United Kingdom
[3]University of Aberdeen, School of Medicine- Medical Sciences and Nutrition, Aberdeen, United Kingdom

Study question: Which semen parameters are predictive of treatment-dependent and treatment-independent reproductive outcomes?

Summary answer: Progressive motility predicted treatment-independent pregnancy, total motile sperm count (TMSC) predicted failed fertilisation with IVF and pregnancy following IUI, and morphology predicted pregnancy after IUI.

What is known already: Semen analysis, an essential component of any fertility work-up, is useful in identifying azoospermia and oligozoospermia, but its

discriminatory capacity to identify fertile and infertile men has been questioned, including by the World Health Organisation (WHO). It has also been suggested that a combination of semen parameters has better predictive value than a single parameter. We conducted a systematic review of the literature to determine the association between different semen parameters and spontaneous (treatment-independent) pregnancy outcomes, as well as pregnancy outcomes following various fertility treatments (treatment-dependent outcomes).

Study design, size, duration: A protocol was registered prospectively with PROSPERO (CRD42021251988). A systematic search of MEDLINE, EMBASE, Web of Science, and the Cochrane Central Register of Controlled Trials was undertaken to include papers published from 1st January 2000 to 25th May 2021. Studies were not limited by language. Two reviewers independently screened the search results and undertook data extraction. Risk of bias assessment was undertaken with the QUADAS-2 or QUIPS tool, depending on study design.

Participants/materials, setting, methods: Studies were eligible if they included men undergoing semen analysis for any indication and reported the accuracy of one or more semen analysis parameters in predicting treatment-dependent or treatment-independent reproductive outcomes – these included fertilisation rate, clinical pregnancy, live birth, and time to pregnancy. Studies were excluded if semen analysis was not the primary test being assessed or no reproductive outcomes were reported.

Main results and the role of chance: Of 5236 publications and 139 full-text articles, 62 studies were included. 52 studies reported treatment-dependent outcomes and 10 reported treatment-independent outcomes. Most treatment-dependent studies lacked key information and were rated as unclear risk of bias in at least one domain (79.3% overall). Half of the treatment-independent studies were high risk of bias in at least one domain.

Of all semen parameters, progressive motility and sperm concentration predicted treatment-independent pregnancy outcomes. Three studies concluded progressive motility predicted pregnancy rates at a range of thresholds (threshold 24%: area under the curve (AUC) 0.909; $<32\%$ vs $\geq 32\%$: adjusted odds ratio (aOR) 4.2 (95% CI 1.1-15) and $<50\%$ vs $\geq 50\%$: aOR 2.8 (95% CI 1.3-6.1); per 10% reduction in progressive motility, pregnancy chances reduced by 11%: hazard ratio (HR) 0.89 (95% CI 0.85-0.93)). Sperm concentration predicted pregnancy within 6 months (≥ 20 vs < 20 million/ml, adjusted rate ratio 0.68 (95% CI 0.52-0.91)) and 12 months (adjusted HR 1.35 (95% CI 1.09-1.66)).

In those undergoing IUI, pre-/post-wash TMSC and morphology predicted pregnancy, but with no clear threshold values. TMSC predicted "total fertilisation failure" in an IVF population (AUC 0.631-0.75). In an ICSI population, no semen parameter predicted fertilisation rate, pregnancy, or live birth rate.

Limitations, reasons for caution: Meta-analysis was not possible due to a wide range of cut-off values used for each semen parameter. Due to the low quality of the evidence included, poorly detailed female populations, and WHO manual methods often not being used for reporting, the findings of this review should be viewed with caution.

Wider implications of the findings: Whilst this review has identified certain semen parameters in isolation are predictive of pregnancy in treatment-dependent and treatment-independent scenarios, clear threshold values have not been identified. This questions the reporting of morphology as it is labour intensive to assess and is only predictive of pregnancy in a population having IUI.

P-066 Testis expressed 44 is essential for spermatogenesis and male fertility

X.J. Zhuang[1], Q. Sun[1], Y. Liu[1], P. Liu[1], X. Zhi[1]

[1]Center of Reproductive Medicine- the Third Hospital of Peking University, Department of Obstetrics and Gynecology, Beijing, China

Study question: Dose Testis expressed 44 (TEX44) gene associated with spermatogenesis and TEX44 mutations required for male infertility ?

Summary answer: TEX44 is expressed in testis and participated in spermatogenesis. And mutations of TEX44 may be involved in risk of asthenozoospermia and lead to subfertile.

What is known already: The World Health Organization estimates that 7-9 % of male population worldwide struggle with infertility. Asthenoteratozoospermia is one of the major factors for male infertility, whereas the causes of large numbers of cases are still unknown.TEX44 is a protein coding gene, which is specifically expressed in male germ cells. However, the expression, localization pattern and precise underlying mechanisms of TEX44 in mouse and human have not been clearly during spermatogenesis and risk of asthenozoospermia.

Study design, size, duration: This study was an analysis of 120 Han Chinese men with asthenoteratozoospermia by whole-exome sequencing(WES), at the Reproductive Medical Center of Peking University Third Hospital between January 2018 and January 2022.All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committees of Peking University Third Hospital and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Participants/materials, setting, methods: Real-time polymerase chain reaction (Q-PCR) and western blot assays (WT) were used to investigate the mRNA and protein levels of TEX44 in testes. Immunofluorescent analysis was performed on testis sections by TEX44 antibodies during the spermatogenesis. TEX44 knockout mice were generated by CRISPR/Cas9 gene-editing. Computer-assisted sperm analysis (CASA) and fertility testing were also carried out to evaluate the effect of TEX44 on spermatogenesis and male reproduction.TEX44 mutation was an analysis of asthenozoospermia patients using WES.

Main results and the role of chance: TEX44 mRNA and protein were found to be expressed at the highest level in mouse testis by Q-PCR and WT. Immunohistochemical results revealed TEX44 was located in the cytoplasm of elongating spermatids and exhibited specific localization to the flagellum and manchette during spermiogenesis. Tex44 knockout mice presented no detectable difference in testis-to-body weight ratios when compared with wild-type mice. However, gross testis morphology shows reduction of testis size in TEX44 knockout mice compared wild-type after 12 weeks old. Tex44(-/-) males are subfertile because of abnormal sperm movement and reduced motility.Proportions of motile and progressive movement showing spermatozoa of TEX44 knockout mice were always 30–50% lower than that in controls using CASA.Tex44-/- mice are fertile despite a significant reduction in sperm motility. But the average total number of mouses born of Tex44-/- mice were decreased ($P < 0.01$). In addition, WES analysis revealed two novel frameshite point mutation patients in TEX44 gene during asthenozoospermia patients. Of these missense mutations, patients with asthenozoospermia have abnormal sperm movement and reduced motility. Fertility could be rescued by the use of intra-cytoplasmic sperm injections (ICSIs).

Limitations, reasons for caution: Additional cases are in need of study, especially with TEX44 mutation patients from only a small number of asthenozoospermia patients. Protein analysis and function were limited. In future investigations, a larger sample size should be used and the role of the interaction proteins with TEX44 should be analyzed.

Wider implications of the findings: TEX44 was validated as spermatids-essential gene could play important roles in spermatogenesis. The identification and characterization of TEX44 enhances our understanding of the molecular mechanisms of spermatids differentiation and provides insight into its potential role in the asthenozoospermia.These found will provide important guidance for genetic counseling and assisted reproduction treatments.

Trial registration number: This study was supported by the National Natural Science Foundation of China (NO.81671513) and Beijing Natural Science Foundation (NO.7172236).

P-067 Characterization of seminal microbiota in patients with asthenozoospermic and normozoospermic using next-generation sequencing

M. Vajpeyee[1], S. Tiwari[1], L.B. Yadav[1], N. Chimote[1]

[1]Pacific Medical University- Pacific Medical College and Hospital, Department of Reproductive Medicine and Research, Udaipur- Rajasthan 313001-, India

Study question: How are the semen microbiota compositions of patients with asthenozoospermic and normozoospermic different, According to data from 16S rRNA gene-specific Next-generation sequencing (NGS)?

Summary answer: Large numbers of microbes can be present in seminal fluid, and there are differences in the semen microbiota between asthenozoospermic and normozoospermic semen samples.

What is known already: Male factor is attributable in up to 50% of cases of infertility. Most studies on normal and abnormal sperm microbiota are based on 16S rRNA gene-specific next-generation sequencing (NGS). Microbiome analysis based on subunit 16S rRNA sequencing is a fast tool that can enable the identification of all the pathogenic microorganisms associated with semen in clinical pathology. Studies on the impact of semen micro-biomes in asthenozoospermic and normozoospermic samples could improve the results of assisted reproductive technologies. The major bacterial diversity in asthenozoospermic and normozoospermic samples belongs to the genera *Lactobacillus*, *Prevotella, Staphylococcus*, and *Anaerococcus.*

Study design, size, duration: Two eighty patients with their own semen samples were included in the study. The study population consists of patients attending to the "Pacific IVF Center" Pacific Medical University and Hospital (Udaipur, India) from November 2020 to October 2022. Depending on the spermiogram results, they were divided into two groups. Group 1 (n = 127) was asthenozoospermic, and Group 2 (n = 153) had normozoospermic semen samples, Patients were aged between (20-45 years). Ethical approval was obtained from the institute.

Participants/materials, setting, methods: Genomic DNA was extracted from samples using commercially available (Qiagen, DNeasy Power Soil kit). The amount of extracted DNA was measured using a Nanodrop spectrophotometer (Thermo Scientific). The microbiota of semen was analyzed using 16S ribosomal RNA (rRNA) gene amplification (MinION) Oxford Nanopore Ltd. Bioinformatics analysis was performed using QIIME2 and Microbiome Analyst packages. Alpha, beta diversity, and taxonomic characterization were compared for the seminal microbiome in asthenozoospermic and normozoospermic semen samples.

Main results and the role of chance: Different bacterial communities were detected when asthenozoospermic and normozoospermic semen samples were analyzed. In patients with asthenozoospermic parameters, a higher alpha diversity index tendency was found. In normozoospermic semen samples, a p-value of bacterial diversity was non-significant ($p = 0.14$ for the Shannon index), and significant differences in asthenozoospermic semen samples ($p = 0.01$ for the Shannon index). In the beta diversity analysis, no significant differences were observed between both groups

Relative abundance analysis identified the bacterial communities, *Lactobacillus, Streptococcus*, and *Ureaplasma* in normozoospermic semen samples, and Anaerococcus and *Gardnerella* in asthenozoospermic samples, Comparison of asthenozoospermic and normozoospermic samples with alpha diversity ($p = 0.06$ for the Shannon index and $p = 0.08$ for the Simpson index) and beta diversity ($p < 0.001$) showed significant differences. Relative abundance in normozoospermic semen samples identified the bacterial communities, *Lactobacillus* ($p = 3.70E\text{-}4$), Prevotella ($p = 8.11E\text{-}4$), and in asthenozoospermic semen samples *Anaerococcus* ($p = 0.004$) and *Gardnerella* ($p = 0.004$).

Limitations, reasons for caution: The limited sample size is the primary constraint of this study. Larger studies with a larger sample size are needed to confirm the distinct microbiome patterns identified in asthenozoospermic and normozoospermic samples in connection to male infertility.

Wider implications of the findings: Further research could determine the detection rate of the described bacterial diversity in semen with other pathologies. Determining the relationship between sperm microbiota characteristics and infertility could enable the development of new algorithms for treating patients with reproductive disorders, An abnormal seminal microbiome appears to be strongly correlated with infertility.

P-068 Real-world data shows that frozen-thawed ejaculates used for ICSI with autologous oocytes have lower but clinically negligible cumulative live birth rates compared to fresh samples

I. Hervas[1], M. Gil Julià[2], M. Cozzolino[3], A. Navarro-Gomezlechon[2], L. Mossetti[1], R. Pacheco[2], R. Rivera-Egea[4], N. Garrido[5]

[1]IVIRMA Roma, IVF Laboratory, Roma, Italy
[2]IVI Foundation, Andrology and Male Infertility Research Group, Valencia, Spain
[3]IVIRMA Roma, Reproductive Medicine, Roma, Italy
[4]IVIRMA Valencia, Andrology and Sperm Bank Laboratory, Valencia, Spain
[5]IVI Foundation, Andrology and Male Infertility Research Group / IVI Foundation Director, Valencia, Spain

Study question: Does frozen-thawed sperm show an impact on success rates in ICSI with autologous oocyte cycles compared to fresh samples?

Summary answer: The slight decrease in cumulative live birth rates (CLBR) compared to using fresh samples should not overshadow the benefits offered by sperm freezing.

What is known already: Sperm freezing offers many advantages for cycle planning, logistics, sample safekeeping and patient comfort, becoming a reliable daily procedure in infertility clinics worldwide. Nevertheless, there is a lack of agreement amongst the published literature on the potential effect of using frozen-thawed sperm samples for ICSI cycles. The present study focused on outcomes of ICSI cycles using autologous oocytes and, in addition to expressing results as classical success rates, it assessed CLBR, which accounts for the contribution of all used oocytes and embryos from the same insemination procedure towards achieving a live birth.

Study design, size, duration: This is a retrospective multicenter observational cohort study involving 84,371 ICSI procedures with patients' autologous oocytes (81,504 with fresh ejaculate semen samples and 2,856 with frozen ejaculate samples) from January 2008 to November 2021. The fresh sample group included real-world data from the clinical records of these patients and cycles from a cohort of 654,019 inseminated oocytes and 117,443 embryos transferred; whereas the frozen sample group considered 22,518 injected oocytes and 3,847 embryos replaced.

Participants/materials, setting, methods: Classical outcomes such as pregnancy rates and live birth rates (LBR) per embryo transfer (ET) were compared between the two study groups. Generalized linear models were used to obtain adjusted odds ratios (adjOR) and p-values for the comparisons. CLBR were expressed per ET, per embryo transferred and used oocyte, and were plotted as Kaplan-Meier curves. These were adjusted to the female patients' age using Cox regression models to obtain adjusted hazard ratios and p-values.

Main results and the role of chance: There were statistically significant differences between both groups in terms of clinical and ongoing pregnancy rates per ET, and LBR per ET. However, after being adjusted to female and male patients' age and BMI, total progressive motile sperm, semen capacitation, transfer before or at the blastocyst stage, and use of PGT, these differences were no longer statistically significant. Once three embryos were replaced, CLBR was 50.50% (49.91-51.08) in the fresh sample group, versus a 45.12% (41.77-48.28) in the frozen sample group. After five embryos transferred, these were 68.21% (67.27-69.13) and 64.62% (57.81-70.33) respectively ($p > 0.001$). The Cox regression resulted in an adjusted hazard ratio (adjHR) of 1.166 (1.076-1.264). The CLBR in the fresh sample group was 33.15% (32.69-33.61) after using 10 oocytes and 49.93% (49.31-50.54) after 14. In the frozen sample group, these were 28.73% (26.24-31.13) and 43.13% (39.78-46.30) ($p > 0.001$). The adjHR for this comparison was 1.220 (1.125-1.322).

Limitations, reasons for caution: The multivariate analyses aim to control to the best of our abilities the main limitation of the study, which is the

potential biases that could be introduced due to the heterogeneity of the data and the retrospective nature of the present study.

Wider implications of the findings: Although frozen samples had slightly decreased CLBR per used oocyte and ET, there were no statistically significant differences in pregnancy and LBR per ET after the multivariate analysis. The extensive real-world data provided shows that slight declines in CLBR should not offset the many advantages that semen freezing offers.

P-069 A male factor panel of NGS can identify the genetic cause of more than half patients with seminal alterations

A. Turienzo Diez[1], E.M. Garcia[1], A. Pay[1], R. Morales[1], F.M. Lozano[1], J.A. Ortiz[1], B. Lledó[1], A. Bernabeu[2], R. Bernabeu[2]

[1]*Instituto Bernabeu, IB Biotech, Alicante, Spain*
[2]*Instituto Bernabeu, Instituto Bernabeu, Alicante, Spain*

Study question: Is Next Generation Sequencing (NGS) an effective diagnostic tool for sperm abnormalities?

Summary answer: NGS male factor gene panel can be a potent diagnostic tool for discovering pathogenic variants linked to sperm abnormalities.

What is known already: Male infertility, responsible for half of infertility cases, often shows as absence or decreased sperm count (azoospermia, criptozoospermia or oligozoospermia), poor motility (asthenozoospermia) or a higher proportion of morphologically abnormal sperm (teratozoospermia).

While the spermiogram remains the gold standard for evaluating male fertility, the potential to identify the molecular basis of sperm abnormalities may make NGS a valuable approach for such patients.

The aim of our study was to assess NGS panel's effectiveness in diagnosing patients with abnormal sperm count, motility and morphology.

Study design, size, duration: A prospective study was conducted from May 2021 to May 2022 in 82 patients including 20 patients with oligozoospermia, 19 with asthenozoospermia and 23 with teratozoospermia. No other sperm alterations were taken into account in each group. The control group consisted of 20 normozoospermic healthy donors selected on the basis of normal sperm parameters according to the WHO criteria (2010).

Patients carrying Y-chromosome microdeletions or abnormal karyotype were excluded.

Participants/materials, setting, methods: Genomic DNA extraction from blood-EDTA of the patients was performed using the commercial MagMax DNA MultiSample Ultra kit and the King-Fisher automated extractor (ThermoFisher®). Next Generation Sequencing (NGS) was done using a panel with 426 genes involved in the spermatogenesis process.

Panel sequencing for identification of genetic variants was performed using Nextera Enrichment technology (Illumina®).

FASTAQ data were processed using BWA and GATK algorithms. VCF files were analysed using Variant Interpreter software and in silico predictors.

Main results and the role of chance: Data analysis showed that thirty-seven of the sixty-two patients were carriers of pathogenic mutations in at least one of the genes included in the panel (37/62,59.6%).

In the oligozoospermic group, eleven patients (11/20,55%) were carriers of pathogenic mutations in:*CFTR, CEP290, WDR66, ESR1, DNAI2, POLG, PIWIL3, GNRHR, MSH5* and *CTNS*.

In the asthenozoospermic group, ten out of nineteen patients (10/19,52.6%) were carriers of pathogenic mutations in:*HS6ST1, PMS2, CYP19A1, DNAI2, POLG, LRRC6, G6PD, CCDC39* and *PIWIL3*.

In the teratozoospermic group, six of the twenty-three patients (6/23,26%) were carriers of pathogenic mutations in:*CFTR, PIWIL3, CYP21A2, SRD5A*.

No pathogenic mutations were detected in the control group.

The analysis showed comparable results among the various spermiogram alterations with no significant difference ($p > 0.05$).

Each variant was found in a single patient per group, except *POLG* and *CCDC39*, which were found in two cases in the oligozoospermic and asthenozoospermic group, respectively, also *CFTR* and *PIWIL3* in two teratozoospermic patients. Besides, it is remarkable that some of the pathogenic variants were present in genes in more than one group:*CFTR* (3/62), *DNAI2* (2/62), *POLG* (3/62) and *PIWIL3* (4/62).

All identified variants were linked with processes of spermatogenesis such as dynein assembly and DNA integrity.

Limitations, reasons for caution: The main limitation of this study is the limited number of patients included.

Functional studies with a larger cohort of males with seminal disorders is warranted to confidently correlate the genetic variants identified in this analysis with spermatogenic failure.

Wider implications of the findings: The gene list included in our panel represents a step-forward in the screening of males with altered sperm parameters.

Our results may add in the knowledge of male factor infertility to provide etiologic factors towards a personalized treatment and adequate genetic counselling.

[8]*Merrion Fertility Clinic/ University College Dublin/ Trinity College Dublin, Reproductive Medicine/ School of Medicine/ School of Biochemistry & Immunology-Trinity Biomedical Sciences Institute, Dublin, Ireland*

Study question: Are SARS-CoV2 antibody isotypes detectable in seminal fluid of vaccinated men

Summary answer: Systemic circulating SARS-CoV2 antibodies are likely to be precluded from transport to seminal plasma following vaccination in males

What is known already: Expedited development of SARS-CoV-2 vaccines led to public concerns regarding impacts of the novel vaccine on gametes in patients seeking assisted reproduction.

Recent studies on ovarian follicular fluid from women post SARS-CoV2 infection or BNT162b2 mRNA vaccination show similar levels of SARS-CoV2 IgG antibodies in follicular fluid as those found in serum. To our knowledge, no study to date has examined if SARS-CoV2 antibody isotypes are detectable in seminal fluid of vaccinated men.

Study design, size, duration: This was a longitudinal cohort study of 17 normospermic male patients attending a fertility clinic associated with a tertiary university maternity hospital. Semen and matched peripheral blood samples were collected prior to vaccination ($t = 0$), within $46 + 18.9$ hours of vaccine completion (acute; $t = 1$) and at $88.4 + 12$ days (3 months; $t = 2$) post vaccination.

Participants/materials, setting, methods: Serum and seminal plasma anti-SARS-CoV-2 spike isotypes (IgA, IgM and IgG1) and immune factors (IL-6, IL-8, IL-10, IFN-γ, TNF-α, IP-10; CXCL10, MCP-1, CCL2) were analysed using ELISA-based approaches at three time points. To rule out potential factors present in seminal plasma that could interfere with IgG detection, a

commercial positive anti-Spike control was used to confirm detection in the ELISA assay. Self-reported symptoms and sperm parameters including count, motility, morphology, DNA damage were also quantified.

Main results and the role of chance: All semen samples were found to be negative for anti-SARS-CoV2 spike antibodies at all three time points indicating that systemic antibodies are likely precluded from transport to seminal plasma. Four out of 17 (23.5%) serum samples were negative for all three isotypes (IgM, IgA, IgG1) at < 72 hours post-vaccine completion, while one patient remained negative for all antibodies at 3 months post-vaccine. No global change from baseline was seen in reported symptoms, mean semen volume, semen pH, sperm concentration, motility, morphology or DNA damage in the acute or long phase. Two men showed a clinically relevant reduction in sperm motility alone in the acute phase that returned to normal by 3 months. Seminal plasma MCP-1 levels showed an acute but transient elevation post-vaccine, while IL-8 was marginally increased 3 months after completion of vaccination. Our findings also indicate a modest, positive correlation between serum levels of the anti-inflammatory cytokine IL-10 and self-reported symptoms in the acute post-vaccine period, with no correlation between serum IL-10 levels and change in sperm parameters from t = 0 to t = 1.

Limitations, reasons for caution: This study included a small population of only 17 men, all of whom were normospermic. Responses in men with subnormal baseline sperm parameters may differ and thus would be helpful to explore.

Wider implications of the findings: Our results show no significant adverse effect of vaccination. There may be temporary decline in sperm motility which could be more significant in men with poor baseline parameters. Further larger studies with inclusion of men with abnormal baseline parameters would be valuable to support timing of vaccination and treatment.

[5]*Kermanshah University of Medical Sciences, Fertility and Infertility Research Center- Health Technology Institute, Kermanshah, Iran*

Study question: Does supplementation of human sperm media with L-Proline improve sperm function and chromatin quality during in Vitro Incubation?

Summary answer: The inclusion of L-proline as an antioxidant in human sperm media improves sperm function and chromatin integrity probably by modulating oxidative stress

What is known already: Infertility affects millions of people of reproductive age globally. The quality of gametes is one of the most critical aspects that could affect the success rate of infertility therapy. The storage of spermatozoa at the incubator to achieve capacitation could rise sperm DNA fragmentation as a result of prolonged incubation. Although mild and low levels of Reactive Oxygen Species (ROS) could boost fertilization capacity by improving hyperactivation, and capacitation, oxidative stress is one of the major contributors to low sperm quality. L-Proline plays a pivotal role in many aspects of cell metabolism and physiology, including osmotic protection and oxidative stress

Study design, size, duration: The study was conducted on thirty-five healthy men attending the Motazedi Hospital, Kermanshah of the Division of Andrology, from December 2020 to June 2021. Each semen sample was equally divided into 4 groups: one group as control and three as treatment groups. The control group contained only sperm media (Hams, F10 medium supplemented with 5 mg/ml HSA). In treatment groups, different concentrations of Proline (1, 2, and 4 mmol/L) were also added.

Participants/materials, setting, methods: 35 normozoospermic men with healthy lifestyles were included. Sperm parameters including motility, viability, and morphology were evaluated. The levels of ROS, lipid peroxidation (LPO), and total antioxidant capacity (TAC) were determined in sperm media. Sperm chromatin integrity was analyzed by Aniline blue (AB), Toluidine blue (TB), and Chromomycin A3 (CMA3) staining tests. DNA fragmentation was measured by the Sperm chromatin dispersion (SCD) test. All assessments were conducted after 1, 4, and 24 hours of incubation.

Main results and the role of chance: The inclusion of Proline (2 mmol/L) resulted in noticeably improved maintenance of motility and viability after 24 hr of incubation compared to the control group ($P < 0.05$). Also, 2 mmol/L of Proline was able to significantly maintain normal morphology compared to other groups ($P < 0.01$). However, the level of ROS production non-significantly diminished in the L-proline groups compared to the control group ($P > 0.05$). In terms of lipid peroxidation, the presence of 2 mmol/L of Proline kept the MDA production of spermatozoa at lower levels after 4 hr of incubation compared with the control group ($P < 0.05$). The supplementation of sperm media with 2 mmol/L of Proline led to improved maintenance of TAC level, compared to any other group ($P < 0.01$). Additionally, the results of AB and TB tests indicated that chromatin quality after supplementation with 2 mmol/L L-proline significantly improved compared to the control group ($P < 0.05$). In terms of CMA3 assessment, however, there was a minor improvement between the 2 mmol/L Proline group and the control group. Moreover, 2 mmol/L Proline significantly reduced the level of fragmented DNA by comparison to the control group after 24 hr of incubation ($P < 0.05$).

Limitations, reasons for caution: Our team was unable to carry out additional studies to verify the impact of L-proline on mitochondrial activity, membrane potential, and apoptosis and to validate the efficiency and safety of L-proline using additional parameters such as the in vitro embryonic development and live birth rate.

Wider implications of the findings: While further studies are required to uncover the mechanisms underlying the antioxidant properties of Proline, these findings extend our knowledge of human male fertility and pave the way to improving the human sperm culture and in vitro procedure routinely used in infertility clinics for sperm incubation.

P-072 Efficacy of a microfluidic chip technology for sperm selection in intrauterine insemination cycles

C. Moutos[1], O. Kocur[1], P. Xie[1], Z. Rosenwaks[1], G. Palermo[1]

[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.*

Study question: Is there an advantage of using a new sperm selection method by microfluidics (MFSS) over standard density gradient (DG) for couples undergoing intrauterine insemination (IUI)?

Summary answer: MFSS reduced sperm processing time and selected spermatozoa with greater progressive motility and superior genomic integrity, suggesting a better clinical outcome than DG.

What is known already: The most conservative, cost-effective reproductive treatments for infertile couples are timed intercourse and IUI. The latter is generally performed using DG to enrich and purify the most motile spermatozoa; it requires technician effort and skills as well adequate processing time. Moreover, during DG centrifugation, spermatozoa are exposed to potentially harmful silica gel particles and eventual reactive oxygen species (ROS). The recent availability of a microfluidic chamber has been proposed as a method to safely process spermatozoa in an expedited manner while reducing human intervention. Therefore, we decided to test MFSS in a laboratory that executes over 2,000 IUI cycles/year.

Study design, size, duration: Since September 2022, 93 couples underwent 103 IUI-MFSS. Post-processing semen parameters and clinical outcomes were compared with those of 103 age-matched couples who underwent 103

IUI-DG during the same period. To confirm findings, 45 couples undergoing their first IUI-MFSS had post-processing semen parameters and clinical outcomes compared with 45 first-time IUI-DG couples, serving as a matched control. Finally, within the same 66 couples, outcomes were compared between their initial IUI-DG cycle and a subsequent IUI-MFSS.

Participants/materials, setting, methods: Men had normal raw semen parameters according to the most recent WHO criteria. DG was performed according to WHO21 guidelines, while MFSS as per manufacturer protocol (ZyMōt® Multi 850µL). Stimulation protocols were similar between all patients. Before and after processing, volume, concentration, and motility were compared between the two processing methods. Sperm chromatin fragmentation (SCF) was assessed by TUNEL (In Situ Cell Death Detection Kit; normal threshold,≤15%). For all comparisons, +bHCG and clinical pregnancy (+FHB) were compared retrospectively.

Main results and the role of chance: Ninety-three couples (maternal age,37.3 ± 4; paternal age,39.2 ± 6) underwent 103 IUI-MFSS cycles and were matched for age and abstinence days (1–4d) to 103 IUI-DG patient/cycles. IUI-DG and IUI-MFSS yielded 0.5 ± 0mL volume, 76.8 ± 40x10^6/mL and 41.3 ± 26x10^6/mL concentrations, and 89.4 ± 3% and 98.3 ± 1% motility, respectively (P<0.001). IUI-DG resulted in a 20.4% +bHCG (21/103) and 15.5% +FHB (16/103). IUI-MFSS yielded a 19.4% +bHCG (20/103) and 16.5% +FHB (17/103).

Forty-five couples (maternal age,36.8 ± 4; paternal age,37.8 ± 6) who underwent their first IUI with MFSSwere matched to a first-time IUI-DG cohort with similar semen parameters and abstinence. IUI-DG led to a 0.5 ± 0 mL volume, 77.3 ± 43x10^6/mL concentration, and 90 ± 2% motility. IUI-MFSS yielded a lower concentration (45.6 ± 27x10^6/mL), but a remarkable increase in motility (98.3 ± 1%) (P<0.001). IUI-DG yielded a 13.3% +bHCG (6/45) and an 8.9% +FHB (4/45). IUI-MFSS yielded a 15.6%(7/45) +bHCG and an 11.1% +FHB (5/45).

Finally, we assessed 66 couples who underwent IUI-DG and subsequently IUI-MFSS. IUI-DG resulted in a 77.5 ± 39x10^6/mL concentration and 89.0 ± 3% motility, while IUI-MFSS resulted in a lower concentration (36.9 ± 21x10^6/mL), but an enhanced motility (98.3 ± 1%)(P<0.001). IUI-DG yielded a 15.2% +bHCG (10/66) and an 8.9% +FHB (5/66), while IUI-MFSS yielded a 15.2% +bHCG (10/66); all became clinically pregnant.

In all comparisons, SCF was 6.5 ± 3% in raw samples, became 4.7 ± 2% after DG, and negligible after MFSS at 0.8 ± 0.6%(P<0.001).

Limitations, reasons for caution: IUI-MFSS cycles yielded a higher number of progressively motile spermatozoa with superior genomic integrity and a comparable clinical outcome to IUI-DG. This study came at a higher cost due to the device and offered only preliminary results. Therefore, it needs to be repeated in a larger study population.

Wider implications of the findings: DG is time consuming, labor intensive, and its outcome is technician-dependent. While reducing exposure to chemicals and ROS, MFSS grants higher motility and superior genomic integrity. If a greater clinical outcome is confirmed in a larger cohort, MFSS may prove to be a superior sperm processing method for IUI.

Trial registration number: not applicable

P-073 Comparison of human preimplantation embryo development after sperm selection for ICSI using the microfluidic ZyMōt device versus density gradient centrifugation

H. Balakaier[1], I. Kuznyetsova[2], A. Chaudary[3], C. Librach[4]

Study question: Does microfluidic sperm selection using ZyMōt device has a significant effect on blastocyst development, ploidy, and improves pregnancy outcomes when compared with density-gradient centrifugation.

Summary answer: The study demonstrated that sperm selection using a microfluidic device had no impact on euploid blastocyst rates or clinical pregnancy outcomes.

What is known already: Selecting competent spermatozoa with the highest genomic integrity for ICSI is a key to achieving normal embryo development and a healthy live birth. Several sperm preparation techniques have long been scrutinized with varied success. The novel microfluidic ZyMōt device appears promising for improving the quality of sperm used in Assisted Reproductive Technologies. Preliminary tests have shown that ZyMōt may increase sperm motility and considerably decrease DNA fragmentation, which could potentially enhance euploid blastocyst development rates. However, the impact of this sperm selection method on clinical outcomes has not been fully investigated.

Study design, size, duration: This is a retrospective cohort study performed in a single academic IVF centre (**IRB # 16367**). Data were collected from 1286 ICSI cycles in 2020-2021 (730 with ZyMōt and 556 with DGC), including 867 cycles with PGT-A outcomes. Morphological grading of 6640 blastocysts cultured in a time lapse imaging incubator (Embryoscope™) and ploidy of 4783 blastocysts using high resolution NGS (Illumina platform and Blue Gnome) were compared between the two study groups.

Participants/materials, setting, methods: All male partners were normo-spermic according to standard semen analysis. ICSI results for a total of 7277 mature oocytes injected with spermatozoa processed with ZyMōt device and 5977 oocytes injected with spermatozoa processed by gradient-density centrifugation were compared. For the analysis of 1478 euploid embryo transfer outcomes, all cases included a single blastocyst transferred in a frozen-thaw cycle. Associated patient characteristics, including age and fertility diagnosis were collected.

Main results and the role of chance: A significantly higher fertilization rate was observed with ZyMōt compared to the gradient prepared sperm (83.4% vs 81.0%, $P = 0.0004$, respectively). The blastocyst rates (61.3%, vs 60.4%, $P = 0.34$) as well as the proportion of high-quality blastocysts were similar in both groups ($P = 0.20$). Euploidy rates were not different between all female age groups, including young egg donors (≤ 30y of age) to patients with advanced maternal age (>40 y of age). Microfluidic sperm selection did not improve clinical pregnancy rates after euploid embryo transfer (42.9% vs 41.4%; $P = 0.58$).

Limitations, reasons for caution: Although this is the largest study to date evaluating application of the ZyMōt device, the retrospective nature and cohort design limited the interpretation of our results. The patient population did not include male factor cases and sperm DFI data was not available. Embryo transfer outcomes were limited to clinical pregnancies.

Wider implications of the findings: The ZyMōt device offers a convenient alternative to standard sperm processing by density gradient method. Further studies are needed to fully determined the impact of ZyMōt on embryo quality and clinical outcomes in different age and diagnosis groups of patients; particularly for those with high DFI and poor IVF/ICSI outcomes.

P-074 In-vitro vitamin D treatment on human sperm improves sperm motility, capacitation, and oocyte activation

W.Y. Ang[1], M. Hamdan[2], G. Nelli[1]

[1]*Universiti Malaya, Department of Physiology, Kuala Lumpur, Malaysia*
[2]*Universiti Malaya, Department of Obstetric and Gynaecology, Kuala Lumpur, Malaysia*

Study question: Does *in-vitro* vitamin D treatment on fertile and infertile human sperm improves sperm motility and alter protein markers involved in capacitation and oocyte-activation.

Summary answer: *In-vitro* vitamin D treatment enhance functionality of sperm by increase intracellular calcium ion, thus increasing sperm motility and capacitation status.

What is known already: Many studies have been done to investigate the relationship between vitamin D and male infertility. It is known that low serum vitamin D in human contribute to male infertility. However, the effect of *in-vitro* vitamin D treatment on sperm remains unclear, particularly on the effect of vitamin D following ejaculation into female reproductive tract. This includes processes involved in fertilisation such as capacitation, hyperpolarization, oocyte activation and sperm-oocyte fusion. Therefore, we examined whether *in-vitro* vitamin D treatment on sperm can improve the sperm parameters, hence will then improve fertilisation and pregnancy.

Study design, size, duration: Randomised controlled trial with prospective interventions (*in-vitro* vitamin D treatment). Based on power analysis, 40 subjects both fertile and infertile men who came for semen analysis were recruited at University Malaya Medical Centre from January 2022 to January 2023. All men were consented to participate in this study. Each washed semen sample were aliquoted to serve as control and receive *in-vitro* vitamin D treatment.

Participants/materials, setting, methods: Total of 40 samples were included for final analysis. All semen samples were washed and treated with 1nM vitamin D *in-vitro* for 45 minutes at 37°C. Motility, intracellular calcium released, capacitation status, mitochondria membrane potential and other basic semen parameters were measured after *in-vitro* vitamin D treatment for fertile and infertile samples. Furthermore, immunofluorescence of sperm origin oocyte activation factor, Phospholipase C Zeta (PLCζ), was done to investigate fluorescence intensity per cell using Image J.

Main results and the role of chance: In both fertile and infertile sample group, total motility is increased after *in-vitro* vitamin D treatment (MD = 8.727%, $P < 0.001$). Fluo-4 AM stain shows there are increase of intracellular calcium release after *in-vitro* vitamin D, with mean difference of Corrected Total Cell Fluorescent (CTCF) for Fluo-4 AM (MD = 25043, $P = 0.0228$. Chlortetracyclin (CTC) test for capacitation status and immunofluorescence of phosphotyrosine shows there are increase CTCF (MD = 0.02595, $P = 0.0142$) after *in-vitro* vitamin D treatment. Staining of JC-1 shows there are more hyperpolarised mitochondria membrane in *in-vitro* vitamin D treatment group compare to the control group. Ratio of red to green fluorescent is 0.639 in control group and 2.22 in *in-vitro* vitamin D treatment group. Moreover, immunofluorescence of sperm origin oocyte activation factor, Phospholipase C Zeta (PLCζ) show *in-vitro* vitamin D improve the expression of these protein. Mean difference of CTCF between control and vitamin D treatment group for PLCζ is 8.013×10^{-3}, $P = 0.0226$. Thus, *in-vitro* vitamin D enhance functionality of sperm by increase intracellular calcium ion, thus increasing sperm capacitation status and sperm membrane hyperpolarization.

Limitations, reasons for caution: Although power analysis is used to calculate sample size, however bigger sample size always needed to increase the accuracy. Moreover, patients' sample are examined and treated after 3 hours due to limited collection room in the facility.

Wider implications of the findings: Vitamin D can be used as a tool in *in-vitro* fertilisation (IVF) procedure and can be added to sperm preparation medium due to its implication in increasing capacitation and hyperpolarised sperm membrane to increase chance of successful IVF.

P-075 Artificial intelligence for sperm analysis: A KNIME-Based automated analysis of sperm morphology

O. Abdelkefi[1], S. Daoud[1], R. Maalej[1], M. Ben Amor[1], A. Sallami[1], T. Rebai[1]

[1]*Medical School ofSfax, Laboratory of Histology-Embryology & Biology of reproduction, sfax, Tunisia*

Study question: To evaluate an automated sperm morphology assessment method using the KNIME Analytics Platform compared to manual sperm morphology analysis performed as per WHO guidelines.

Summary answer: Our method emphasizes how artificial intelligence technologies have the potential to foster standardization of sperm morphology assessment with comparable precision and reliability.

What is known already: Manual sperm morphology assessment is considered the most difficult parameter to standardize due to its subjective nature, strongly linked to the operator's level of expertise. Indeed, there is a high degree of inter and intra-laboratory variability. Manual examination is time-consuming and laborious. There were many attempts to automate sperm morphology analysis, especially with CASA (Computer Assisted Sperm Analysis) systems, but their performance is still disputable. One of the difficulties in this field of study is the lack of publicly available datasets. Besides, the available databases are only focused on the sperm head morphology.

Study design, size, duration: A total of 37 semen samples from men attending our laboratory for infertility investigation were included, over a period of one year. For each sample, semen smears were fixed and stained by the Spermoscan® kit.

Participants/materials, setting, methods: A total of 1000 images of individual spermatozoa were obtained using the MMC® CASA system. The number of images per sample depended on its quality. Three experts have classified these spermatozoa according to modified David classification for sperm morphology. The results were then processed and an algorithm created using teh KNIME Analytics Platform, trained and tested to classify spermatozoa. This workflow uses CNN (convolutional neural network) to perform image classification on our dataset.

Main results and the role of chance: Of the 1000 images analyzed, we counted : 116 Normal sperm morphology, 67 abnormal post-acrosomal region, 128 abnormal acrosomes, 8 elongated heads, 6 thin heads,10 microcephalic,7 multiple heads, 27 coiled tails, 7 cytoplasmic residues, 17 angulated tails, 6 short tails, 4 multiple tails, and 697 associated abnormalities. For each image, a notebook file containing sperm abnormalities as assessed by the three experts was created, in addition to sperm head, mid-piece and tail dimensions obtained by the CASA system.

Our dataset was randomly partitioned into 2 groups: 80% of data formed the training set, and

The remaining 20% formed the fully independent test set.

The best performance with the KNIME-Based algorithm was achieved for post-acrosomal abnormalities (97 % True positive rate), and the worst for multiple tail abnormalities (69 % True positive rate). Our machine learning model classifies sperm morphology at high accuracy (99.5 %). The overall process occurs in less than 10 seconds.

Limitations, reasons for caution: Our database included various head, midpiece and tail anomalies. However, the number of images in each category is unequal due to the limited occurrence of some morphological abnormalities. Thus, it is important to increase the number of images in these categories to obtain better results.

Wider implications of the findings: Our goal is to expand our modified David's classification-based database. We aim to improve the performance of our model, and to put it at the service of learning and routine use in laboratories.

Trial registration number: not applicable

P-076 Sperm selection by thermotaxis: a novel technique to enhance assisted reproductive technologies' outcomes

K. Guleresi[1], S. Santos Ribeiro[2], S. Reis Soares[2], S. Nunes Gouveia[1], S. Gómez Alves[3]

[1]*Instituto Valenciano de Infertilidad, IVF Laboratory, Lisboa, Portugal*
[2]*Instituto Valenciano de Infertilidad, Reproductive Medicine Consultation, Lisboa, Portugal*
[3]*Instituto Valenciano de Infertilidad, Andrology Laboratory, Lisboa, Portugal*

Study question: Does sperm selection by thermotaxis increase competent spermatozoa count?

Summary answer: When compared to capacitation alone, our findings suggest an improvement in the availability of high quality spermatozoa after thermotaxis in terms of motility and morphology.

What is known already: Thermotaxis is a natural mechanism that guides competent spermatozoa through the female genital tract. It has been previously shown that, in the mice model, thermotaxis may improve pregnancy rates following *in vitro* fertilization (IVF). However, thus far, there is little information to support these findings with human spermatozoa.

Study design, size, duration: A prospective single-center paired pilot analysis was performed between April 2021 and April 2022 including 21 male individuals, 12 of whom were sperm donors and 9 who were patients with asthenozoospermia (defined as < 32% progressive sperm motility).

Participants/materials, setting, methods: Only otherwise healthy men between 18 and 45 years old were included. All subjects performed a sperm collection at the clinic after a maximum of 3 days following the last ejaculation. Sperm concentration, motility, morphology (all using the WHO 2010 criteria) and DNA fragmentation (TUNEL) were assessed within the same sample at three time-points: fresh sample, after capacitation and following the extra thermotaxis procedure.

Main results and the role of chance: The average age of the participants was 34.9 ± 6.6 years old. The mean sperm concentration was 66.9 ± 39.1 million/mL (91.4 ± 26.1 in the donor subset (group A) versus 34.2 ± 28.0 in the asthenozoospermia patient (group B) subgroup). The median sperm motility was 62.0% (66.5% in group A versus 24.0% in group B). The mean sperm morphology was 7.2% (7.7% in the group A versus 6.7% in the group B). When compared to the sample in which only capacitation was performed, a statistically significant increase in spermatozoa motility (52.10% vs 82.14%, $p < 0.05$) and normal morphology (11% vs 16%, $p < 0.05$) was observed following capacitation plus thermotaxis. Conversely, DNA fragmentation did not vary significantly within the capacitated samples before and after thermotaxis (13% vs 14%).

Limitations, reasons for caution: The present pilot study is based on a limited number of participants and should be extended further.

Wider implications of the findings: The combination improvement in terms of morphology and progressive motility following thermotaxis may optimize selection of sperm cells and ultimately increase pregnancy rates after IVF. In the light of our experience, it is possible that this technique, which does not require high-end equipment, may increase the usable competent spermatozoa count.

Study question: Does the culture media and the protocols used for sperm processing and cryopreservation significantly affect DNA integrity? How does it correlate to other sperm parameters?

Summary answer: In one of the analyzed media, the DNA damage was significantly higher after swim-up. DNA integrity is negatively correlated with concentration, vitality and motility.

What is known already: DNA fragmentation index (DFI) has proven to be a valuable tool in the diagnosis of infertility since men evaluated as normozoospermic in the seminogram may have high levels of sperm DNA fragmentation.There is already evidence of sperm DNA fragmentation affecting fertility, though the use of this information in ART is limited. The study of DNA fragmentation is relevant in fresh samples but also in processed and/or cryopreserved samples, since these procedures are likely to alter the sperm DNA integrity and change the treatment's outcome. Extended culture times, media composition or even the performed protocol may induce those changes.

Study design, size, duration: The sperm sample collection was performed at CETI (Porto, Portugal) for 4 years. During this time, 207 seminogram samples were evaluated for DNA integrity using the Toluidine Blue test (TB) and Pearson's correlation was applied. From that pool, 30 samples were selected to evaluate the impact of time and media used for swim-up protocols. Other 30 samples were analyzed for comparison after cryopreservation with two different media. In both cases an ANOVA test was applied.

Participants/materials, setting, methods: Men aged between 17 to 62 years old, collected a sperm sample for seminogram analysis according to the WHO and ESHRE criteria. After their informed consent was given, the same sample was used to test three different culture media. Swim-up technique was applied and the upper portion was removed for motility, concentration and DFI evaluation. Additionally, two distinct cryoprotectants (glycerol or egg yolk) were compared for sperm motility and DNA integrity before and after cryopreservation.

Main results and the role of chance: In this study, DNA integrity was evaluated using TB staining, a simple and affordable method for indirect assessment of DFI. DNA integrity was negatively correlated ($p < 0.0001$) with concentration ($r = -0.301$), vitality ($r = -0.421$), morphology ($r = -0.278$) and total motility ($r = -0.280$). Moreover, normozoospermic samples showed higher DNA integrity than samples with at least one impaired parameter ($p < 0.0001$). ROC curve analysis was used to establish a diagnostic threshold, above which samples are potentially damaged and consequently may lead to infertility situations. This value is around 21%, which could be an advance for the clinical application of this method, making the evaluation of DFI fair to all ART laboratories. Also, it was found that the incubation at room temperature may be beneficial since it improved sperm motility after 1h and 2h (respectively $p = 0{,}0016$ and $p = 0{,}0130$) compared to incubation at 37°C with the same medium. All media recorded an increase in DNA damage over time. There were no significant statistical differences between cryopreservation media. However, the results suggest that the medium with egg yolk cryoprotectant may promote greater stability and membrane fluidity, decreasing the impact on sperm motility and DNA damage caused by the cryopreservation process.

Limitations, reasons for caution: These results should be taken with caution and, in order to strengthen them, additional samples should be analyzed. Also, the correlation between different sperm parameters is based on comparisons between several individuals who exhibit some interpersonal variability and was based on traditional semen analysis, which is slightly subjective.

Wider implications of the findings: The establishment of a threshold for DFI may be useful for daily practice. We observed that media rich in aminoacids and proteins promote sperm motility after swim-up and that room-temperature incubation is also beneficial. We concluded that media with egg yolk may promote greater sperm motility and less DNA damage.

P-078 In vitro effects of polycarbophil vaginal moisturizing gel on sperm motility and vitality

M. Mendonça Carneiro[1], A.C. Goulart[2], D. Alvarenga[2], R. Bossi[2], M. Sampaio[2], S. Geber[2], F. Reis[1]

[1]Universidade Federal de Minas Gerais UFMG, Obstetrics and Gynecology, Belo Horizonte, Brazil
[2]Origen Centro de Medicina Reprodutiva, IVF Lab, Belo Horizonte, Brazil

Study question: The aim of this study was to evaluate the possible effects of intravaginal polycarbophil gel in sperm quality in an *in vitro* model.

Summary answer: Incubation of human sperm samples with a vaginal moisturizer containing polycarbophil gel 10% resulted in important reduction of sperm motility and vitality.

What is known already: The possible effect of lubricants on sperm quality has been a matter of debate for over 50 years. Despite the publication of a few studies, the real impact of lubricants on male gametes is remains unknown. Some commercial lubricants have been tested but so far there is a lack of studies evaluating the impact of vaginal moisturizers on seminal quality. Vaginal dryness is a recurring and significant complaint affecting couples trying to conceive who may use lubricants, vaginal moisturizers or even natural oils that could advsersely interfere with seminal quality.

Study design, size, duration: This paired prospective study involved seminal samples obtained fom 14 men undergoing fertility treatment at a private IVF clinic in Brazil from August/2020 to July/2022. The study was approved by the local review board and each participant signed an informed consent. Each sample was divided into two aliquots: 20% polycarbophil gel (final dilution 10%) or medium only. Statistical analysis was performed using D'Agostino/ Pearson, General Linear Model, Wilcoxon, Friedman's. P values <0.05 were considered significant.

Participants/materials, setting, methods: Normozoospermic samples of 14 patients (alpha 0.05, power 0.8)were collected by masturbation, 2 to 5 days after the last ejaculation. After liquefaction ,10 µmL were analyzed using a Makler chamber according to World Helath Organization (WHO) guidelines. Samples were mixed 1:1 v/v with 20% policarbophil gel or with culture medium only, then incubated for 24h at 34°c. Analysis were performed at 0, 15, 30 min and 24h to determine progressive motility and vitality (eosin-nigrosin test)

Main results and the role of chance: There was a significant decrease of sperm motility according to the WHO classification in both experimental conditions over time, but the reduction was more evident in the samples treated with polycarbophil gel ($p<0.0001$ group x time, General LinearModel for Repeated Measure).

The proportion of progressively motile sperm reduced immediately upon contact of the seminal sample with polycarbophil gel (time point 0 min) and decreased throughout the experiment, contrasting to incubation with culture medium (control), which only affected substantially sperm motility after 24h. In the validation cohort, the proportion of progressively motile sperm decreased from a median of 52% in fresh samples to 11% after 24h incubation with culture medium and 0% after 24h incubation with polycarbophil gel ($p<0.0001$).

Sperm vitality at the end of the experiment also differed significantly between treatments, with medians of 62.5% after exposure to culture medium and 47% after exposure to polycarbophil gel ($p=0.020$, Wilcoxon's test)

Limitations, reasons for caution: Results represent samples from a selected group of men undergoing fertility treatment at a private center in Brazil. The effect of polycarbophil gel in fertile males may be different. Moreover, the *in vitro* setting used here does not accurately mimic the vaginal environment which could interfere with the results.

Wider implications of the findings: Polycarbophil-based gels and similar products may harm sperm vitality and motility, therefore woment trying to conceive should avoid the use of such products until more studies prove otherwise.

P-079 Transcriptomic Analysis of Seminal Plasma in NOA Men as a Predictor of Successful Testicular Sperm Extraction

L. Ng[1], S. Cheung[1], P. Xie[1], Z. Rosenwaks[1], G. Palermo[1]

[1]Weill Cornell Medicine, Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York City, U.S.A.

Study question: Could transcriptomic profiling of semen ejaculate be used to predict successful testicular sperm retrieval for men with idiopathic non-obstructive azoospermia (iNOA)?

Summary answer: Transcriptomic analysis of seminal plasma RNA in iNOA men revealed gene imbalances that consistently correlated with the success of retrieving spermatozoa via a testicular biopsy.

What is known already: Although microdissection testicular sperm extraction (m-TESE) in NOA men results in successful spermatozoa retrieval in about 60% of the cases, it is difficult to predict which cases will fail to recover sperm. While several algorithms have been proposed to make this prediction, such as age, serum FSH, inhibin B, and genetics, there is no one factor that can do so reliably. Even histopathology fails to be more accurate, and it is equally invasive. Recently, epigenetic analysis on testicular biopsy specimens has shown a differential gene expression in relation to the origin of azoospermia and spermatogenic function.

Study design, size, duration: Over a 3-year period, 23 men diagnosed with iNOA underwent repeated extensive semen analyses and were deemed azoospermic. These patients were categorized based on whether spermatozoa were subsequently retrieved (+Sperm) or not (-Sperm) at micro-TESE. Transcriptomic analysis was performed by RNAseq, and significant differentially expressed gene (DEG) profiles were assessed and compared between the two cohorts. DNAseq was then used to confirm our findings.

Participants/materials, setting, methods: RNA and DNA were isolated from seminal plasma using a commercially available spin column kit and sequenced by Illumina HiSeq 3000/4000 platform at 2x150bp. Transcriptomic profiling was carried out in comparison to a fertile donor control and among the two cohorts. An absolute log2fold change of >1 and a P-value of <0.0005 were considered statistically significant.

Main results and the role of chance: Transcriptomic analyses of ejaculates from 23 azoospermic men were assessed for a total of 21,855 genes against a fertile donor control. Subsequently, 11/23 (47.8%) men (39.0 ± 12yrs) underwent successful testicular sperm retrievals. Their DEG profiles revealed 1,409 imbalanced genes. However, 13 were consistently imbalanced among them: 8 involved in spermatogenesis and 5 in sperm function.

Alternatively, for the 12 men in the –Sperm cohort (34.3 ± 5yrs), 1,265 imbalanced genes were identified with 12 common imbalanced genes associated with spermatogenesis ($n=5$), sperm function ($n=3$), sperm maturation ($n=1$), and cell cycle regulation ($n=3$).

When comparing the DEG profiles between the + and –Sperm cohorts, 8 commonly shared imbalanced genes were identified. IGSF11-AS1, a gene expressed in the testis and implicated in spermatid development, was consistently underexpressed in all –Sperm men. TPTE2, a testis-specific gene regulating spermatogenesis, was overexpressed in 81.8% (9/11) of the individuals in the +Sperm cohort and conversely underexpressed in the -Sperm group.

Most interestingly, NEU1, involved in acrosome development and fertilization, was consistently overexpressed in all individuals of the +Sperm group, yet clearly underexpressed in the entire –Sperm group. DNAseq showed that the NEU1 gene exhibited a synonymous mutation for the +Sperm group and a frameshift mutation in the –Sperm group.

Limitations, reasons for caution: Using noninvasive RNAseq and DNAseq on the seminal plasma has allowed us to identify DEGs that may be used to predict whether a patient with iNOA will have a successful or failed retrieval with micro-TESE. However, these results are preliminary and should be further validated in a larger study cohort.

Wider implications of the findings: Transcriptomics on the ejaculates of men with iNOA represents a noninvasive tool to detect the presence of residual spermatogenesis. Once confirmed, these findings may help guide

patients in weighing their exposure to anesthesia and surgical risks. This would help to mitigate patient emotional and financial distress.

P-080 Enzymatic tissue processing after testicular biopsy in non-obstructive azoospermia enhances sperm retrieval and cumulative live birth rates

V. Vloeberghs[1], A. Racca[2], N. De Munck[1], I. Mateizel[1], H. Tournaye[1]

[1]*UZ Brussel, Centre for Reproductive Medicine, Jette- Brussels, Belgium*
[2]*Dexeus University Hospital, Fertility, Barcelona, Spain*

Study question: What is the added value of enzymatic processing of testicular biopsies on testicular sperm retrieval rates in patients with non-obstructive azoospermia (NOA)?

Summary answer: In addition to mechanical mincing, enzymatic digestion increased sperm retrieval rates in testicular biopsies of NOA patients with 48.9%.

What is known already: Many studies focus on the surgical approach to optimize recovery of testicular sperm in NOA, and in spite of that, there is still controversy whether the type of surgery makes any difference as long as multiple biopsies are taken. Few studies, however, focus on the role of the IVF laboratory and the benefit of additional lab procedures, like enzymatic digestion, in order to optimize sperm retrieval rates and CLB rate per TESE.

Study design, size, duration: A retrospective single-center cohort study including all patients who underwent their first TESE by open multiple-biopsy method from January 2004 till July 2022. Only patients with a normal karyotype, absence of Y-q deletions and a strict diagnosis of NOA based on histology were included. Primary outcome was sperm retrieval after mincing or enzymes for intracytoplasmic sperm injection (ICSI). Secondary outcome was CLB after ICSI with fresh TESE, and subsequent ICSI cycles with frozen TESE.

Participants/materials, setting, methods: Multiple biopsies were obtained from the testis, unilateral or bilateral, on the day of oocyte retrieval. Upon mechanical mincing, dishes were searched for 30 min; when no or insufficient numbers of spermatozoa were observed, enzymatic treatment was performed using collagenase type IV.

Multivariable regression analysis was performed to predict CLB by adjusting for the following confounding factors: male age, male FSH level, cryptorchidism, enzymatic digestion, number of oocytes and female age.

Main results and the role of chance: Hundred-eighteen patients were included of which 61.0% had successful sperm retrieval. Spermatozoa were retrieved after mechanical mincing (23.7%; 28/118) or after additional enzymatic digestion of the remaining 90 patients (48.9%; 44/90).

Mean male characteristics were not different between patients with sperm retrieval after mincing or enzymes: age (34.5 vs 34.5 y), testis volume (10.2 vs 10.6 ml), FSH (17.8 vs 16.9 IU/l), cryptorchidism (21.4 vs 34.1%) and histological diagnosis (Sertoli Cell Only 53.6 vs 47.7%, maturation arrest 21.4 vs 38.6%, sclerosis/atrophy 25.0 vs 13.6%), respectively.

Of the 72 patients with sperm available for ICSI, 23/72 (31.9%) obtained a LB after the injection with fresh testicular sperm (fresh and frozen embryo transfers). Forty-nine patients remained without LB, of which 34 had supernumerary testicular sperm frozen. Of these, 9/47 (47.4%) had a LB after ICSI with frozen testicular sperm, giving rise to a total CLB per TESE of 32/118 (27.1%) or 32/72 (44.4%) CLB per TESE with sperm.

Of the female characteristics (couples with sperm available), only female age (30.3 vs 32.7 y – p = 0,042) was significantly lower in the group with a live birth.

Multivariable logistic regression analysis showed that enzymatic digestion was associated with significant decrease of CLB per TESE.

Limitations, reasons for caution: Limitations of the study are related to the retrospective design. The selection of only NOA patients with specific characteristics (normal karyotype and absence Y-q deletion) and having their first TESE ever strengthens our findings. Whether enzymatic digestion after a failed TESE without digestion may improve retrieval rate remains undecided.

Wider implications of the findings: Enzymatic processing increases the sperm retrieval rate from testicular biopsies of NOA patients compared to mechanical mincing, demonstrating the importance of an appropriate laboratory protocol. NOA patients should be counselled that if sperm has been found after enzymatic digestion, their chances to father a genetically own child will be lower.

Abstract citation ID: dead093.446

P-081 In utero exposure to diisopentyl phthalate (DiPeP) disrupts the expression of steroidogenesis-related genes and induces multinucleated gonocytes in the fetal rat testis

M. Weffort[1], D. De Araujo dos Santos[1], M. Passoni[2], A. Martino Andrade[1]

[1]*Federal University of Parana, Physiology, Curitiba, Brazil*
[2]*Federal University of Parana, Pharmacology, Curitiba, Brazil*

Study question: Can the plasticizer diisopentyl phthalate (DiPeP) disrupt testosterone biosynthesis and alter fetal rat testis histology similarly to other common toxic phthalates?

Summary answer: DiPeP can dose-dependently suppress mRNA levels of steroidogenic genes and induce multinucleated gonocytes in the fetal rat testis, resembling the effects of other toxic phthalates.

What is known already: DiPeP is an uncommon phthalate, whose metabolites have been ubiquitously detected in urinary samples from Brazilian pregnant women and children. These results, which contrast with the undetected levels of DiPeP metabolites in other human biomonitoring studies worldwide, led us to investigate DiPeP reproductive and developmental toxicity in rats. Our preliminary data indicate that DiPeP is a potent antiandrogenic phthalate, but no studies have been conducted to assess the impact of DiPeP exposures on the incidence of multinucleated gonocytes in the rat fetal testis, a common feature of the rat phthalate syndrome.

Study design, size, duration: Pregnant Wistar rats (n = 7-9 dams/group) were treated orally (gavage) with DiPeP 0 (control), 11, 33, and 100 mg/kg/day between gestation days 14-20. Dose levels were based on prior rat phthalate toxicity studies and canola oil was used as a vehicle. On gestation day 20, dams were euthanized and up to three male fetuses from each litter were removed for the collection of fetal testes and the assessment of the study endpoints.

Participants/materials, setting, methods: Fetal rat testes were used for enzyme immunoassay quantification of testosterone production following *ex vivo* incubation of testes in culture media, analysis of mRNA levels of steroidogenic genes and insulin-like factor 3 (*Insl3*) by quantitative polymerase chain reaction (qPCR), and histological assessment of multinucleated gonocytes by optical microscopy.

Main results and the role of chance: No signs of systemic toxicity were observed as indicated by the lack of alterations in maternal body weights and the unchanged number, viability, and weight of fetuses. There were no significant changes in the *ex vivo* testosterone production at any DiPeP dose. On the other hand, DiPeP induced significant reductions in the mRNA expression of key steroidogenic genes, including suppressed mRNA levels of the steroidogenic acute regulatory protein (*Star*) and cytochrome P450 family 11 subfamily A member 1 (*Cyp11a1*) at 100 mg/kg/day and of cytochrome P450 family 17 subfamily A member 1 (*Cyp17a1*) at 33 and 100 mg/kg/day. Gene expression of *Insl3*, which is essential for the process of testis descent, was reduced at the highest dose by 58% in relation to control, but this change was not significant (p = 0.07). The number of multinucleated gonocytes, corrected for the number of testicular cord sections or the total area of analyzed testicular cords was significantly increased in the groups exposed to 33 and 100 mg/kg/day. Chance is an unlikely explanation for our results considering the observed dose-dependent responses and the consistency of our findings with prior phthalate reproductive toxicity data.

Limitations, reasons for caution: The tested doses are higher than the expected human exposure levels and animal-to-human extrapolation should be done with caution.

Wider implications of the findings: DiPeP suppresses the expression of steroidogenic genes and induces multinucleated gonocytes in the fetal rat testis. These endpoints seem more sensitive than inhibition of *ex vivo* testosterone production. Although human exposure levels are lower than the doses tested here, DiPeP can potentially act cumulatively with chemicals that share similar mechanisms.

[2]Dr. I. Cantacuzino Hospital, OG Department, Bucharest, Romania
[3]C.I. Parhon National Institute of Endocrinology, Endocrinology, Bucharest, Romania
[4]Stefan S Nicolau Institute of Virology, Department of Molecular Virology, Bucharest, Romania

Study question: Investigating estradiol in relation with other sperm parameters might reveal new correlations which would help our understanding of male idiopathic infertility

Summary answer: Statistical significance was found in a series of correlations of E2 levels and sperm, hormonal and health parameters

What is known already: Male infertility is a rising major health concern, with sperm counts decreasing by 50-60% in the recent decades. The causes for male infertility are very different (genetic, systemic, neurological, infections, trauma, etc.), but at least 44% of cases are idiopathic. Estradiol (E2) regulates spermatogenesis by binding to classical intracellular estrogen receptors or membrane estrogen receptors to trigger genomic and nongenomic signal transduction pathways. Although E2 doesn't carry any prognostic value by itself, as its levels don't vary significantly between infertile and fertile men, its association with other parameters may lead to a better understanding of male infertility

Study design, size, duration: the design of cross-sectional study comprising 111 subjects- 87 infertile patients (median: 34 years, range 20–55 years) and 24 control (median: 33 years, range 20–45 years). The subjects were included in this study during 3 years (between October 2019- September2022). Inclusion criteria: spermatic parameters according to WHO 2010 Standards Exclusion criteria: Radiotherapy and/or pelvic chemotherapy (over the last 6 months), known genetic aberrations, endocrine diseases, urogenital infections, bilateral orchiectomy, vasectomy and occupational exposure.

Participants/materials, setting, methods: Infertile men were grouped in azoospermia (AZOO), oligoasthenoteratozoospermia (OATS/OATSS) and oligoasthenozoospermia (OAS/OASS). Blood and semen samples were collected and E2 levels were measured in both seminal and blood samples, along with sperm parameters (sperm count, motility, morphology) and other factors (BMI, hormone and vitamin D levels, BsmI polymorphism in the vitamin D receptor gene) were evaluated. E2 levels were assayed using the electrochemiluminescence method with the RocheCobas E601 autoanalyzer.

Main results and the role of chance: E2 varies slightly between the different patients' groups, the highest values being found in the OAT/OATSS group. BMI is higher in the infertile group; significant higher values were found for the OAS/OASS ($p = 0.002$) and OATS/OATS ($p = 0.017$) groups.

Statistical analysis has revealed a significant difference between serum and seminal E2 levels in each group (AZOO $p = 0.0355$; OATS/OATSS $p = 0.0156$; control $p = 0.0009$), but also between OATS/OATSS seminal group and control seminal group ($p = 0.0366$). The E2/Inhibin ratio presented higher values in patients with OATS/OATSS ($p = 0.0031$) and azoospermia ($p = 0.0059$). The lowest values of E2/Vitamin D ratio were detected in the OAS/OASS and OATS/OATSS groups ($p = 0.0254$), A significant increase of E2 serum level was observed in patients from the OATS/OATSS group in the case of homozygous for mutant allele of BsmI polymorphism ($p = 0.0419$). The results bring new evidence regarding the role of E2 in male infertility. The obtained data indicates an interplay between E2 and Inhibin B and vitamin D serum levels, highlighting it's the role in male infertility.

Limitations, reasons for caution: The study could be extended to a larger population sample, in order to further validate the obtained results

Wider implications of the findings: Estradiol activity plays an important role in male fertility and along with the investigated parameters could serve as potential markers in the diagnosis and management of male infertility.

P-083 Associations of sperm epigenetic aging with semen parameters among men from the U.S. general population

R. Pilsner[1], S. Sawant[1], E. Houle[1], O. Oladele[1]

[1]Wayne State University, OB-GYN, Detroit, U.S.A.

Study question: Is sperm epigenetic aging (SEA) associated with semen parameters among men in the general population?

Summary answer: While SEA was not associated with general semen parameters, advanced SEA was positively associated with sperm head defects such as length, perimeter, and pyriforms.

What is known already: We have previously shown that advanced SEA was strongly associated with longer time-to-pregnancy among couples in the general population.

Study design, size, duration: A population-based prospective cohort study of couples discontinuing contraception to become pregnant recruited from 16 US counties from 2005 to 2009.

Participants/materials, setting, methods: Sperm DNA methylation from 379 semen samples were assessed via Illumina EPIC Array and SEA was estimated using Super Learner, an ensemble machine learning algorithm. Linear regression models were employed to examine the associations between semen parameters and SEA adjusting for male age and current smoking.

Main results and the role of chance: None of the general semen characteristics such as count, concentration, motility or morphology were associated with SEA. However, several sperm head parameters were positively associated with SEA including length ($\beta = 3.6$, 95% confidence internal (CI): 1.01 - 6.23; $p = 0.007$); perimeter ($\beta = 4.04$, 95% CI: 0.1 – 0.05; $p = 0.045$) and pyriforms ($\beta = 0.29$, 95% CI: 0.1-0.49; $p = 0.003$). SEA was also inversely related to sperm elongation factor ($\beta = -2.9$, 95% CI: -4.8 - -1.1; $p = 0.002$).

Limitations, reasons for caution: This prospective cohort study consisted primarily of Caucasian men and women and thus large diverse cohorts are necessary to confirm the associations between SEA and sperm head defects in other races/ethnicities.

Wider implications of the findings: These data suggest that advanced sperm epigenetic aging may be related to improper sperm head condensation during spermatogenesis.

P-084 Oral antioxidant supplementation ameliorates the deleterious effects of plasticizers Bisphenol AF (BPAF) and Dibutyl Phthalate (DBP) on mouse sperm DNA integrity

J. Drevet[1], E. Hug[2], P. Villeneuve[3], S. Bravard[2], C. Damon-Soubeyrand[2], A. Moazamian[4], R. Geurtsen[4], J.R. Aitken[5], F. Saez[2], P. Gharagozloo[4]

[1]GReD Institute, INSERM U1103 CNRS6293, Clermont-Ferrand, France
[2]GReD, Biology, Clermont-Ferrand, France
[3]GReD Institute, Biology, Clermont-Ferrand, France
[4]Celloxess LLC, Biotech, Ewing, U.S.A.
[5]University of Newcastle, Life sciences, Newcastle, Australia

Study question: Do common chemicals in plastic, BPAF and DBP, negatively impact sperm parameters and DNA integrity, and can oral antioxidant supplementation mitigate their impact?

Summary answer: Short-term, low-dose exposure to BPAF or DBP did not impact testicular/epididymal histology but caudal epididymal sperm parameters, particularly DNA integrity was significantly compromised.

What is known already: Plasticizers are among the most commonly produced chemicals worldwide with 90% of people showing detectable levels in their urine. As endocrine disruptors (EDCs), they act as estrogen mimetics but can also induce oxidative stress and form DNA adducts. Numerous studies have linked exposure to EDCs to impaired spermatogenesis, sperm DNA damage and male infertility. Limited studies suggest antioxidants may alleviate the reproductive toxicity of EDCs. This study measured the effects of short-term exposures to two common environmental EDCs (BPAF & DBP) on the post-testicular compartment epididymis and investigate the efficacy of an oral antioxidant supplement to safeguard sperm DNA integrity.

Study design, size, duration: Adult male CD1 mice were exposed to low doses (50mg/kg) of BPAF or DBP with or without co-administration of antioxidant supplementation (Fertilix®) for 14 days and evaluated after euthanasia.

Participants/materials, setting, methods: All experiments were performed at the University Clermont Auvergne, Clermont-Ferrand, France. Mice were supplemented with BPAF, DBP or/and Fertilix® in their drinking water. The results of exposure of males were evaluated against controls and included: testicular and epididymal histology, epididymal ROS status via 4-HNE levels in caput protein extracts, general semen parameters: (count, motility, viability, acrosome integrity), sperm nuclear/DNA parameters [decondensation (Toluidine blue stain), fragmentation (TUNEL test), oxidation (8-OHdG residue level)].

Main results and the role of chance: The histology of the testis and epididymis was unaffected by the exposure conditions used. An oxidative stress situation was evident by the EDC exposures, demonstrated by increased level of 4-HNE adducts in the epididymal caput protein extracts. Viability, total and progressive motility, and acrosome integrity of caudal epididymal spermatozoa remained unaltered in exposed animals compared with controls. Exposure to BPAF but not DBP significantly decreased sperm count. Sperm nuclear/DNA integrity assessed by the percentages of sperm with decondensed and oxidized nuclei was significantly increased in EDC-exposed animals. Sperm DNA fragmentation did not significantly increase in any group of exposed animals. Co-administration with Fertilix® significantly corrected the defective sperm parameters (nuclear decondensation and DNA base oxidation) with the exception of sperm count which did not return to control levels in BPAF+ Fertilix® treated animals. These data confirm that even at low doses and short-term exposures, epididymal spermatozoa are susceptible to DNA damage induced by environmental ROS-generating EDCs, confirming its association with male infertility.

Limitations, reasons for caution: The translation of these findings to humans needs to be confirmed, although the nuclear compartment of human sperm is more susceptible to oxidative alterations than that of the mouse.

Wider implications of the findings: These data demonstrate the susceptibility of post-testicular sperm cells to common environmental chemicals. They also support the use of appropriate antioxidant supplementation as an effective therapeutic choice for individuals with multiple exposures to environmental stressors such as ROS-generating EDCs.

P-085 Reactive molecules drive sperm capacitation via protein posttranslational modifications

H. Řimnáčová[1], M. Iniesta Cuerda[1], J. Moravec[1], J. Nevoral[1]

[1]*Faculty of medicine in Pilsen- Charles University, Biomedical center, Pilsen, Czech Republic*

Study question: Are S-sulfenylation and S-nitrosylation, two essential post-translational modifications (PTMs), increased during sperm capacitation? Which proteins are subjected to S-sulfenylation?

Summary answer: S-sulfenylation and S-nitrosylation increase during sperm capacitation. S-sulfenylation affects certain proteins, including A-kinase anchor protein 13, Fibrilline-1, and Spermatogenesis-associated protein 7.

What is known already: There is a significant increase in reactive oxygen species (ROS) and reactive nitrogen species (RNS) production within sperm capacitation. In contrast to tyrosine phosphorylation, a well-established mark of sperm capacitation, ROS, and RNS lead to PTMs themselves and modify thiol groups of cysteines. Despite these facts, the dynamics of ROS/RNS-derived PTMs during sperm capacitation remain unknown. Therefore, we consider both S-nitrosylation and S-sulfenylation of sperm proteins as novel modifications associated with the capacitation.

Study design, size, duration: C57BL6 mouse sperm were isolated from the *caudae epididymae* of 12-20-week-old males (n = 5). The study compared non-capacitated and capacitated spermatozoa using proteomic profiling.

Participants/materials, setting, methods: Sperm proteins were extracted into RIPA buffer. The protein lysate was incubated with 5mM dimedone, a hapten that specifically labels S-sulfenylated proteins, and immunogenically detected with an anti-dimedone antibody (Merk, Germany). Alternatively, S-nitrosylated proteins were detected by the anti-nitrosocysteine antibody (Merk, Germany). S-sulfenylated and S-nitrosylated proteins were visualized by western blotting. S-sulfenylated proteins were simultaneously identified by mass spectrometry.

Main results and the role of chance: We demonstrated an increase in S-sulfenylation and S-nitrosylation along with sperm capacitation. In addition, both S-sulfenylation and S-nitrosylation are positively correlated with tyrosine phosphorylation. Using mass spectrometry, we identified S-sulfenylated proteins, mostly belonging to the cytoskeleton: A-kinase anchor protein 13, Fibrilline-1, Spermatogenesis-associated protein 7, and Rab-like protein 2A.

Limitations, reasons for caution: The limitation of this study is the instability of PTMs. ROS/RNS-derived PTMs hypothetically arise and cease during protein sample preparation. The experiment was limited to one animal model. Further experiments should be performed on other mammalian models.

Wider implications of the findings: Studying novel sperm PTMs and their mechanism of action may improve the diagnosis of male infertility. Further, it could bring a novel approach to modulate the fertilizing ability of sperm used for in vitro fertilization.

P-086 Prevalence and clinical factors associated with biochemical hypogonadism in infertile men with non-obstructive azoospermia: a single-center cohort study including 761 patients

A. Achermann[1], S. Esteves[1]

[1]*ANDROFERT and University of Campinas UNICAMP, Andrology, Campinas, Brazil*

Study question: What is the prevalence, and which factors are associated with hypogonadism in infertile men with non-obstructive azoospermia (NOA)?

Summary answer: The prevalence of biochemical hypogonadism among NOA males is significant. The condition is associated with testicular volume, estradiol levels, paternal age, and testicular histopathology results.

What is known already: NOA is a severe and irreversible condition that accounts for approximately 60% of azoospermia cases, primarily associated with intrinsic testicular deficiencies of various causes. NOA men can present signs of hypogonadism, associated or not with elevated circulating FSH levels; however, the exact prevalence is ill-reported. There is also a lack of data on the clinical factors associated with hypogonadism. We, therefore, estimated the prevalence of biochemical hypogonadism using real-world data and investigated its relationship with clinical factors.

Study design, size, duration: An observational cohort study was conducted, including 767 consecutive NOA patients with primary spermatogenic failure seeking fertility treatment at a University-affiliated tertiary center for

male reproductive health between January 2014 and September 2021. Biochemical hypogonadism was defined as total testosterone (T) levels <350 ng/dL, measured by chemiluminescence immunoassay from a venous sample, collected in the morning, from 8:00 to 10:00 am, and confirmed on a second analysis at least one week apart.

Participants/materials, setting, methods: All included patients (age range: 23-55 years) had complete clinical, hormonal, genetic, seminal, and histopathology data and were naïve concerning previous sperm retrieval attempts. Patients with NOA due to hypogonadotropic hypogonadism and those using hormonal therapy were excluded. Prevalence rates were computed by Goodman's method. The relationship between clinical factors and hypogonadism was assessed by logistic regression analysis. We also assessed the frequency of patients with high and within-range FSH levels in the cohort.

Main results and the role of chance: NOA patients with biochemical hypogonadism represented 80.3% (95% confidence interval [CI] 77.3–43.7) of the studied population. The median (interquartile range [IQR]) of T and FSH levels in hypogonadal men were 276 ng/dL (233.0-303 ng/dL) and 12.3 IU/L (8.9-18.2). Among them, hypergonadotropic (FSH>12 IU/L) and normogonadotropic (within-range FSH levels 1.5-12.0 IU/L) patients were 52.1% (95% CI 48.1-56.0) and 47.8% (43.9-51.8) of studied individuals, respectively. Logistic regression analyses revealed that testicular volume ($p < 0.0001$) and estradiol levels ($p = 0.0005$) had a significant inverse relationship with hypogonadism, whereas paternal age ($p = 0.02$) showed a positive relationship. Moreover, testicular histopathology was a relevant predictor ($p = 0.003$), with an inverse relationship between hypogonadism and germ cell maturation arrest and a positive relationship between hypogonadism and hypospermatogenesis or Sertoli cell-only. Using these variables, a model constructed to predict hypogonadism had an area under the ROC curve of 0.72.

Limitations, reasons for caution: Limitations include possible unmeasured confounding factors and the intra- and inter-assay electrochemiluminescence method variability. Another limitation is that the study center is a referral facility for azoospermic patients; thus, hypogonadism prevalence rates reported herein might not represent that of the general population of NOA males attending general fertility centers.

Wider implications of the findings: Efforts are needed to provide adequate care for this population due to its association with poor quality of life. Moreover, as recent evidence has suggested that hormonal therapy to boost T production might increase sperm retrieval success rates, studies investigating hormonal therapy in such patients may be warranted.

P-087 Expanding the comparison of an AI automated semen analyses for concentration determinations with manual analyses and a cell counting system

S. Rogers[1], M. Monteiro[2], V. Noblet[2], Z. Simon[2], M. Alvarez Martinez[3], X. Viñals Gonzalez[3], M. Romero[4], A.M. Kjøge[4], N. Jørgensen[4], D. Thomas[2]

[1]Mojo Fertility, Andrology Hub, London, United Kingdom
[2]Mojo Nanovare SAS, Artificial Intelligence, Lyon, France
[3]Aria Fertility, Embryology, London, United Kingdom
[4]Rigshospitalet, University Department 0f Growth and Reproduction, Copenhagen, Denmark

Study question: Can comparable results be obtained for sperm concentrations determinations in differing clinical settings when using an AI driven analyser, a cytometer, and WHO manual counts?

Summary answer: Outcomes suggest that comparable results can be obtained when utilising the differing counting techniques.

What is known already: Despite robust methods described by WHO, protocol variations exist, creating a lack of reproducible and consistent semen analysis results in standard laboratories, as described by Bjorndahl etal 2016. Human error can influence results where WHO protocols are not utilised in conjunction with rigorous IQA and EQA. A human performing an analysis is considered the gold standard, but it's apparent, as demonstrated by time-lapse embryo evaluation, that human assessments can be enhanced with machine assistance to increase accuracy. To establish the benefit of machine assistance, it is necessary to demonstrate comparable results with the manual operator and reliable machine cell counters.

Study design, size, duration: To assess whether comparable results could be obtained with a well-trained reproductive scientist and a cell counting system, two reputable IVF clinics were selected to perform their standard analyses and perform a repeat test with an automated analyser. A number of semen analyses were performed over a six-month time-period for patients attending IVF clinics for a pre-treatment evaluation.

Participants/materials, setting, methods: 107 samples were collected and analysed between June 2022 to December 2023 in laboratories in Copenhagen and London. Participants were selected on a random basis. The semen analyses were performed in a manner described by the WHO6, with an additional assessment with a NucleoCounter™ chemometec in the Danish laboratory. Simultaneously, a concentration determination was performed on a Mojo AISA ™. (Artificial Intelligence Semen Analysis system).

Main results and the role of chance: Manual concentration assessments, the cytometer data and the AISA concentration results were plotted and examined. Comparable values were obtained when data for the manual assessment v AI machine assessment and the data obtained for fluorescent marked sperm v AI analysis were assessed. A significant Spearman correlation was obtained by the manual analysis team and the team who used the cytometer counting system, values of 0.93 and 0.99, (error average 17.5 and 24.4) respectively.

Limitations, reasons for caution: Increasing the sample frame of this current study, including more laboratories for a multi-centre trial would increase the power of the findings. Inter and intra operator and repeat machine evaluations are planned to establish the human variations during analysis and establish if this can be mitigated by machine assistance.

Wider implications of the findings: The results demonstrate that a machine assisted semen analysis is comparable to a gold standard semen analysis performed by a reputable laboratory staff either when compared to a manual operator and to a cell sorting system where sperm are labelled with a fluorescent probe.

P-089 effect of testis tissue retrieval on "Micro Mapping Testicular Extraction" (MMTE): comparison with microscopic testicular sperm extraction (Micro TESE) in non-obstructive azoospermia (NOA)

T. Tai[1,2], S. Shibasaki[3], M. Takahashi[3], N. Okuyama[4], H. Hattori[3,4], S. Nagaura[5], K. Yoshinaga[6], M. Koizumi[5], M. Toya[5], T. Hashimoto[6], H. Igarashi[5], K. Kyono[5,6]

[1]Kyono ART Clinic Sendai, Urology, Sendai, Japan
[2]Kyono ART Clinic Takanawa, Urology, Tokyo, Japan
[3]Kyono ART Clinic Sendai, Lab, Sendai, Japan
[4]Kyono ART Clinic Takanawa, Lab, Tokyo, Japan
[5]Kyono ART Clinic Sendai, Gynecology, Sendai, Japan
[6]Kyono ART Clinic Takanawa, Gynecology, Tokyo, Japan

Study question: Is a new sperm retrieval method, Micro Mapping Testicular Extraction (MMTE) comparable to that of Microscopic testicular sperm extraction (Micro TESE)?

Summary answer: MMTE is comparable to that of Micro TESE regarding sperm retrieval rate (SRR). It can reduce tissue damage and improve intracytoplasmic sperm injection (ICSI) results.

What is known already: Micro TESE is currently the standard technique for sperm retrieval in NOA. However, the large incision severely damages testicles, complicating repeated Micro TESE, and there is a high risk of testicular atrophy and hypogonadism. New technologies, such as FNA mapping, have also been reported, but these require multiple surgeries, long operation times, and high examination costs. A more accurate and minimally invasive method of sperm retrieval is needed, using a shorter and simpler procedure.

Study design, size, duration: MMTE requires only a small amount of testicular tissue, obtained through multiple needle holes in the tunica albuginea by micro-squeezing under a microscope. Tissue is divided into four testicular areas: ventral-upper, ventral-lower, dorsal-upper, and dorsal-lower, and samples are immediately searched for sperm. If sperm are found, a small incision is made in the area with good sperm and additional tissue is taken under the microscope. If no sperm are found, routine Micro TESE is performed.

Participants/materials, setting, methods: From January to November 2022, 25 NOA cases (35.9+/-4.85 years) with indications for Micro TESE were eligible: 15 idiopathic, 6 gr/gr deletion, 2 Klinefelter's syndrome, 1 b2b4 deletion and 1 other.

MMTE was performed on 45 testes: 5 unilateral (Group A) cases and 20 bilateral (Group B) cases. If sperm were found, they were cryopreserved and later used or will be used for ICSI.

Main results and the role of chance: After MMTE, sperm were found in all 5 cases in Group A. In group B, sperm were found in 6 cases after MMTE. For those sperm positive 11 cases, additional sampling was performed to gain enough sperm for ICSI.

Micro TESE was performed for the rest of group B (14 cases, 28 testes), in which no sperm was found by MMTE. Of 2 cases out of 14 cases, only a few sperm were found by Micro TESE. No sperm was found in the rest of 12 cases.

As a result, the SRR per patient was 52% (13/25). The weight of tissue sampled was 56.2 mg (15.6-96.2 mg) by MMTE and 224.6mg (206.4-433.2 mg) by Micro TESE, a significant difference. ($p < 0.05$).

To date, ICSI has been performed in the MMTE-positive 11 cases with a partner (33.8+/-3.4 years). In those cases, the fertilization rate was 62.7% (79/126). The blastocyst rate was 31.7% (40/126), and the pregnancy rate per transfer was 75% (6/8). The total testosterone levels before and 1 month after surgery were significantly reduced only in the cases in which no sperm were found by MMTE.

Limitations, reasons for caution: Two cases that were sperm-positive only by Micro TESE had severe tissue degeneration and tissue was difficult to retrieve from needle holes, so countermeasures were necessary. It is necessary to consider the number of needle holes depending on the size of the testis. The number of cases is still small.

Wider implications of the findings: MMTE can correct tissue just under the albuginea and can cover areas that are difficult to reach with Micro TESE. The sample can be taken through a small incision, so tissue damage is limited to that of Simple TESE, which improves ICSI results by taking sperm from the best areas.

Trial registration number: non applicable

P-090 The in vitro motility characteristics of human sperm collected by microfluidic device

K. Kojima[1], T. Kobayashi[2], M. Okabe[1], Y. Okada[1], M. Fujita[1], K. Takahashi[1]

[1]Takahashi Women's Clinic, Reproductive Medicen, Chiba, Japan
[2]Chiba University School of Medicine, Department of Reproductive Medicine, Chiba, Japan

Study question: Do the *in vitro* motility characteristics of sperm collected using a microfluidic device (ZyMot) differ from those of sperm collected by density gradient centrifugation (DGC)?

Summary answer: ZyMot-collected sperm had longer-lasting motility than those collected by DGC, but the head beat-cross frequency was inferior due to the absence of washing *in vitro*.

What is known already: ZyMot (DxNow, Inc., USA) can sort highly motile sperm with low reactive oxygen species (ROS), and DNA damage, without centrifugation. In IUI cycles, although the total number of ZyMot collected sperm was lower than that of DGC, it was reported that the pregnancy rate of ZyMot cycles was higher than that of DGC cycles. Washing sperm with a medium is essential for *in vitro* capacitation; however, the protocol for microfluidic devices lacks this procedure. The aim of this study was to clarify the motility characteristics of ZyMot-collected sperm. We also examined how washing ZyMot-collected sperm affected motility.

Study design, size, duration: The specimens were provided by patients who underwent semen analysis between October 2022 and January 2023, with written consent. We used 12 samples with a semen volume of 2.5 ml or more, or a motile sperm concentration of 4 million/ml or more. The same donor samples were divided into three groups (DGC, ZyMot, and ZyMot with wash). Dunnett's test was performed with the DGC group as the control group.

Participants/materials, setting, methods: In the DGC group, 2-layer DGC (400G, 20 min) was performed, followed by washing (400G, 5 min). In the ZyMot group, ZyMot was used according to the manufacturer's protocol. In the ZyMot with wash group, ZyMot-collected sperm was centrifugally washed (300G, 5 min). All samples were cultured at 30 °C until motility analysis. Sperm motility was analyzed using a computer-assisted sperm analysis system (SMAS) after 0, 4, and 24 h of semen preparation.

Main results and the role of chance: There was no significant difference in the motility rate of the two ZyMot groups compared to that of the DGC group at 0 and 4h after sperm preparation. On the other hand, the motility of the ZyMot group tended to be higher (53.3%, $p = 0.0787$), and the motility of the ZyMot with wash group was significantly higher (85.4%, $p < 0.001$) than that of the DGC group (33.5%), after 24h of sperm preparation. The straight-line velocity, curvilinear velocity, and average speed of the ZyMot and ZyMot with wash group did not differ from those of the DGC group at 0 and 4h. All speed parameters of the ZyMot with wash group were significantly higher than those of the DGC group, after 24h of culturing. Regarding sperm head movement, there was no significant difference in the amplitude of lateral head displacement between the two ZyMot groups compared to that of the DGC group at 0 and 4h of culture. In contrast, the sperm head beat-cross frequency of the ZyMot group was lower than that of the DGC group (9.18 ± 0.31 Hz vs 8.71 ± 0.49 Hz, $p = 0.0409$). Both head movement parameters of the ZyMot with wash group were significantly higher than those of the DGC group.

Limitations, reasons for caution: We chose semen samples with a high number of motile sperm because we divided the sperm into three experimental groups. Therefore, it is unclear whether our findings are applicable to patients with poor semen parameters.

Wider implications of the findings: ZyMot may be advantageous for IUI cycles because ZyMot-collected sperm maintains sustainable motility for extended periods. Alternately, ZyMot may be unfavorable compared to DGC in conventional IVF cycles due to inferior sperm head movement, which is a marker of capacitation. However, this disadvantage can be overcome by washing.

[5]Materno-Fetal and Reproduction Research Unit- University Hospital of Lausanne CHUV, Department Woman-mother-child-, Lausanne, Switzerland

Study question: Is there a crosstalk between the male and female genital microbiota of couples undergoing assisted reproductive technology (ART) and the outcome of this treatment.

Summary answer: Despite the presence of bacteria linked with bacterial vaginosis in male samples, there appears to be very limited impact on the microbiota of female partners.

What is known already: In recent years, thanks to advancements in sequencing technologies, the microbiota has been explored extensively and many of its roles in human physiology were deciphered. Compared to its female counterpart, male genital microbiota has been understudied. Presence of bacteria in sperm was generally associated with a pathological condition, but recent reports indicate that the male genital tract is colonized by bacteria and even good quality semen generally contains bacteria. Previously three main semen microbiota profiles were identified, two of these were composed of bacteria, usually found in the vagina, indicating that bacteria could be shared between partners during sexual intercourse.

Study design, size, duration: Prospective observational study including 65 couples receiving ART between 2018 and 2020 at a single fertility center in Switzerland, to investigate the interaction of male and female reproductive tract microbiota. Samples were collected by swabbing penile skin and seminal fluid as well as vagina and follicular fluid.

Participants/materials, setting, methods: Samples of 64 infertile couples undergoing ART were collected by direct sampling (vagina and penis glans) or by immersion in the biological fluid (follicular fluid and semen). Follicular fluid was obtained during oocyte pick-up. Sampling of vagina and penis glans (self-sampling) as well as immersion of semen was performed on the same day.

16S rRNA profiling (next generation sequencing) was used to characterize bacterial populations in the samples using a previously developed pipeline.

Main results and the role of chance: *Lactobacillus spp.* were highly prevalent in follicular fluid samples and especially in vaginal samples. Generally, penis glans samples were highly colonized by different bacteria and showed the highest alpha diversity. Follicular fluid and semen samples had generally low bacterial biomass. *Lactobacillus iners* was the most prevalent species in female samples. This is also the case for male samples, although the abundance was lower.

For male patients, comparison of beta diversities showed that intra-individual samples were more similar compared to same sample types from different individuals. The opposite was observed for vaginal samples, where inter-individual differences were less marked compared to samples of the same woman. Similar analyses were performed to evaluate relatedness of samples from the same couple, allowing us to estimate the possible impact of microbiota interaction between partners. Despite generally high values, in several cases intra-couple dissimilarities were significantly lower when compared to same sample type of different individuals.

Analysis of differently abundant taxa showed, as expected, that *Lactobacillus* genus was enriched in female samples, along with *Atopobium spp.* A higher number of genera was specifically enriched in male samples, including *Prevotella*, *Campylobacter* and *Mobiluncus* genera among others.

Limitations, reasons for caution: Limitations of this study are, that it is only observational and the number of patients included is relatively small.

Wider implications of the findings: Our results suggest a very limited impact of male microbiota on the female bacterial colonization, despite male samples were enriched with bacterial genera negatively associated with reproduction. Future analysis of the influence of sexual activity on the microbial composition should comprise samples obtained before and after sexual intercourse.

[5]*Ivfqc, Research & Development, New York, U.S.A.*

Study question: Is it possible to classify sperm morphology as normal or abnormal based on their kinetic characteristics?

Summary answer: Using different classifiers, it was found that balanced dataset the classification scores of individual sperm morphology can be optimized during their motility just before ICSI

What is known already: Sperm selection plays a crucial role during ICSI. This selection by the embryologists is accompanied by two factors: motility parameters of the sperm to be injected, as well as the morphology. Motility affects morphological decision-making which may be subjective due to spermatozoa not being in a narrow vertical space in a PVP droplet, i.e. counting chamber. Machine/Deep Learning models -as classifiers- are gaining popularity in IVF as it could minimize subjectivity in gamete selection. SiD software is an algorithm that from a group of spermatozoa characteristics can support the selection of a single sperm during real time ICSI.

Study design, size, duration: In this prospective study 1699 individual spermatozoa were video-recorded (resolution of 200 X 200 pix.) during sperm selection in a 7%PVP solution. Motility variables (VSL, VCL, LIN, VAP, ALH, WOB, STR, MAD) were obtained from each video using the software SiD. Each sperm was classified as normal or abnormal. Based on motility variables, different classification models were used to make a morphokinetic association of the variables with the classification of each sperm.

Participants/materials, setting, methods: 1699 individual spermatozoa were classified and labeled by three senior embryologists into two categories: normal or anormal. To belong to any category, at least two embryologists had to agree. A normalization was applied to the motility data obtained with SiD. Machine learning classification models were applied. The three classification models with the best results were selected to optimize the hyperparameters and improve their performance.

Main results and the role of chance: A set of motility variables were obtained using the software SiD1 (IVF2.0 Ltd., UK) these were used as features for each of the sperm samples and were tagged either as normal or abnormal having a total of 257 normal samples and 1442 abnormal samples. Different classification algorithms were used to perform sperm classification as normal and abnormal. Then hyperparameter tuning algorithms such as GridSearch were used to compute the optimum values, finding KNN algorithm to achieve the best results to classify normal and abnormal spermatozoa with 80% accuracy. Given the nature of the unbalanced dataset, the F1 score was calculated, achieving 0.77, other algorithms such as Decision-Tree and Random-Forest were used achieving similar results in the F1 score. We will continue growing the dataset until it is balanced and run the same algorithms expecting the performance to improve.

Limitations, reasons for caution: Each clinic's laboratory setup, including the camera used to record the ICSI procedure, is a clinic-specific configuration. Sperm abnormality detection is sensitive to camera resolution, showing the classifiers are resolution-dependent observers. To replicate these results, it is important to consider the quality of the camera.

Wider implications of the findings: Using the selected kinematics features, it is possible to classify individual spermatozoa during motility as having normal or abnormal morphology. Results may improve using standard morphological examination of each population and having more normal sperm samples.

[4]Department Global Andrology Forum, Institute American Center for Reproductive Medicine, Ohio, U.S.A.

Study question: Can the overall intracellular Ca2+ dynamics evoked by progesterone stimulation predict the fertilizing potential of a non-normozoospermic semen sample under fertility treatment?

Summary answer: Some kinetic parameters of the transient intracellular Ca2+ increase evoked by progesterone stimulation correlate with fertilization rates in conventional IVF but not with ICSI.

What is known already: Stimulation with female hormone progesterone induces the activation of the sperm-specific ion channel CatSper which in turn produces a fast increase in the intracellular Ca2+ concentration ([Ca2+]i). After reaching a maximum [Ca2+]i, different Ca2+ clearance mechanisms become active producing a transient followed by a plateau. We investigated whether the [Ca2+]i dynamics upon progesterone stimulus may be used to assess the fertilizing potential of sperm samples from men undergoing assisted reproduction.

Study design, size, duration: This prospective study employed unidentified semen samples from 39 non-normozoospermic men (age 38 ± 6 years old) undergoing fertility treatment from March 2022 to the present at CITMER Reproductive Medicine, Mexico City. Frozen semen samples and ART procedures with less than 3 oocytes were excluded. Ten normozoospermic semen samples were also analyzed. The progesterone-dependent [Ca2+]i changes were evaluated using time-lapse flow cytometry.

Participants/materials, setting, methods: Semen samples were obtained on the same day as oocyte retrieval. Sperm cells were washed and incubated in capacitating HTF media for further use in conventional IVF or ICSI procedures. When available, the surplus cells were stained with vitality and Ca2+-sensitive fluorescent dyes. Fluorescence changes were evaluated by AccuriC6 flow cytometer. Progesterone-induced [Ca2+]i transient as well as the correlations with the fertilization rates were calculated using custom-made R programming language code.

Main results and the role of chance: The progesterone (1 μM) stimulation evoked a fast and transitory increase in the [Ca2+]i. We then calculated six different kinetics parameters of such responses: basal Ca2+ level, increase and decrease in velocity, maximum Ca2+ level, total response duration, and the area under the curve (AUC). There were no significant differences in any of these parameters between normozoospermic donors (and non-normozoospermic patients. The former group of semen samples were divided into either conventional IVF (n = 17) or ICSI (n = 21). In IVF but not ICSI samples, the duration, and the area under the curve of the progesterone response tended to be higher than in normozoospermic (2.39 ± 0.7 min, p = 0.03, and 113 ± 30 AUF*min, p = 0.18, respectively). Furthermore, both parameters showed a tendency to correlate negatively with the conventional IVF (R= –0.45, p = 0.07 and R= –0. 5, p = 0.04, respectively) but not with ICSI fertilization ratio (number of zygotes/total number of mature oocytes). These results suggest that cells with a better Ca2+ recovery mechanism are well suited for IVF. Interestingly, we observed no difference between the magnitude of the [Ca2+]i increase after progesterone stimulus among donors, IVF, or ICSI samples, as was previously reported. Differences in the concentration of progesterone could explain such results.

Limitations, reasons for caution: The preliminary nature of the results implies a necessity to increase the number of analyzed semen samples (in progress). It is well known that progesterone induces variable responses even among the same donor cells. Our population-based analysis may be underestimating such single cells variations.

Wider implications of the findings: Current protocols for sperm analysis fail to successfully predict the fertilizing capability of semen samples from men seeking reproductive treatment. Further research into the molecular regulation of Ca2+ dynamics could offer promising alternatives for clinicians to appropriately choose between IVF and ICSI for each couple.

P-095 Increased sperm high DNA stainability is associated with a diminished chance of fertilization with IVF cycles: a retrospective study using a propensity score-matching analysis

W. Huang[1], M. Song[1], L. Ye[1], W. Xiao[1], Y. Peng[1], J. Liang[1]

[1]Shenzhen Zhongshan Urology Hospital, Urology- Shenzhen Key Laboratory of Reproductive Immunology for Peri-implantation- Shenzhen Zhongshan Institute for Reproduction and Genetics- Guangdong Engineering Technology Research Center of Reproductive Immunol,

Study question: To investigate the association of high DNA stainability (HDS) with fertilization, embryonic development and clinical outcome after IVF treatment.

Summary answer: Increased HDS levels might be associated with decreased fertilization of IVF cycle.

What is known already: The HDS parameter of sperm suggests loosening and weakening of chromatin condensation structure resulting from the lack of full histone-to-protamine exchange. Elevated HDS may negatively correlate with sperm quality, including sperm morphology and concentration.

Study design, size, duration: Couples that underwent IVF cycles from January 2016 to December 2020 were retrospectively studied, including a total of 2604 target cycles after IVF treatment consisting of 676 cycles in the HDS > 15% group and 1928 cycles in the HDS ≤ 15% group. In addition, 548 cycles undergoing fresh IVF-embryo transplantation treatment consisting of 151 cycles in the HDS > 15% group and 397 in the HDS ≤ 15% group were included.

Participants/materials, setting, methods: HDS was assessed by sperm chromatin structure assay method. Couples were classified into HDS > 15% group and HDS ≤ 15% group based on the HDS thresholds recommended by the manufacturer's instructions. After controlling the bias between groups by the propensity score-matching method, the Mann-Whitney U test or Chi-squared test was used to evaluate the differences between groups. Regression analysis was used to assess the effect of HDS levels on fertilization, embryo quality, and clinical outcome of IVF cycles

Main results and the role of chance: No significant differences were observed between the HDS > 15% group and HDS ≤ 15% group regarding the number of fertilized oocytes (10.00 [6.00, 15.00] *vs.* 10.00 [6.00, 15.00], $P = 0.230$), the number of 2 pronuclei zygotes (8.00 [4.00, 12.00] *vs.* 8.00 [5.00, 12.00], $P = 0.311$), the number of cleaved zygotes (10.00 [5.00, 15.00] *vs.* 10.00 [6.00, 15.00], $P = 0.301$), and the number of high-quality embryos on day 3 (5.00 [2.00, 9.00] *vs.* 5.00 [3.00, 9.00], $P = 0.729$). However, linear regression analysis showed that HDS levels negatively impacted fertilization (adjusted B value = −0.015, 95% CI: −0.028 ~ −0.002, $P = 0.022$) and 2 pronuclei formation (adjusted B value = −0.015, 95% CI: −0.029 ~ 0.000, $P = 0.046$). The implantation rate (47.1% *vs.* 50.2%, $P = 0.418$), clinical pregnancy rate (60.9% *vs.* 64.5%, $P = 0.440$), ongoing pregnancy rate (83.7% *vs.* 86.7%, $P = 0.475$), early miscarriage rate (16.3% *vs.* 13.3%, $P = 0.475$), late miscarriage rate (1.1% *vs.* 3.5%, $P = 0.232$), and live birth rate (82.6% *vs.* 83.2%, $P = 0.896$) were not significantly different between groups. Linear regression analysis showed that HDS did not affect the implantation rate. Binary logistic regression analysis also showed that HDS did not affect clinical pregnancy, ongoing pregnancy, early miscarriage, late miscarriage, and live birth.

Limitations, reasons for caution: The main weakness of this study was the nature of the retrospective design, and additionally, patients were not randomized.

Wider implications of the findings: Although our results are not entirely new, it can be considered as reliable because 2604 IVF cycles and 548 fresh IVF-ET cycles were included and subsequently controlled the bias between groups This study suggested that HDS might be an indicator in predicting the fertilization ability of sperm in IVF treatment.

P-096 Prediction of fertilization success by voltage-dependent intracellular Ca2+ dynamics in non-normozoospermic human semen samples undergoing in vitro fertilization: preliminary results

A. Matamoros Volante[1], P. Torres Rodriguez[1], L.B. Ramírez-Dominguez[2], M. Soriano[1], G. Carrasquel-Martinez[2], D. Flores[1], I. Jiménez[2], I. Maldonado[2], L. Villar[2], A. Agarwal[3,4]

[1]Biotechnology Institute- Universidad Nacional Autónoma de México, Department of Developmental Genetics and Molecular Physiology, Cuernavaca, Mexico

[4]Cleveland Clinic Foundation, Cleveland Clinic Foundation, Ohio, U.S.A.

Study question: Does the change in intracellular calcium levels evoked by artificial membrane depolarizations predict fertilization success in a non-normozoospermic semen sample undergoing assisted reproductive techniques?

Summary answer: The increase in the intracellular calcium after artificial plasma membrane depolarization correlates negatively with fertilization rates in conventional IVF but not with ICSI

What is known already: Sperm capacitation-related features, like the regulation of the intracellular calcium concentration ([Ca2+]i) and the hyperpolarization of the plasma membrane potential (Vm), have been proposed as predictors of success during artificial reproduction techniques (ART). Intriguingly, upon Vm depolarization, sperm exhibit a rapid and transitory increase in the [Ca2+]i controlled, likely, by the activation of the sperm-specific calcium channel CatSper. The regulation of CatSper activity is essential for sperm function and is crucial for fertilization. Therefore we wondered if the Vm depolarization-dependent rise in the [Ca2+]i can be used to predict fertilization success rates in non-normozoospermic semen samples of men undergoing ART.

Study design, size, duration: This prospective study employed unidentified semen samples from 29 non-normozoospermic men (37.8 ± 5.6 years old) undergoing fertility treatment from March 2022 to the present at CITMER Reproductive Medicine, Mexico City. Frozen semen samples and procedures with less than 3 oocytes were excluded. Ten normozoospermic semen samples were analyzed as a control. The depolarization-dependent [Ca2+]i changes were evaluated by flow cytometry under four different Vm conditions: resting (variable among samples), –64, –46, and –32 mV.

Participants/materials, setting, methods: Semen samples were obtained on the same day as oocyte retrieval. Sperm cells were washed and incubated in capacitating HTF media for further use in conventional IVF or ICSI procedures. When available, the surplus cells were stained with vitality, Ca2+, and Vm-sensitive fluorescent dyes. Fluorescence changes were evaluated by AccuriC6 flow cytometer. The kinetical analysis of the transitory [Ca2+]i increase as well as the statistical comparisons were performed using custom-made R programming language code.

Main results and the role of chance: Analysis of resting Vm showed that normozoospermic semen samples presented more depolarized Vm than non-normozoospermic controls (–75.7 ± 6.9 vs –67.3 ± 10.5 mV, respectively, $p = 0.02$). The former group of semen samples was either used for conventional IVF ($n = 11$) or ICSI ($n = 14$). The semen samples in these last categories showed a tendency to present a more depolarized Vm than non-normozoospermic samples (–69.9 ± 8.8 and –66.6 ± 11.3 mV, respectively). No differences were seen in the resting Ca2+ levels. We then induced a Vm hyperpolarization by adding the K+ ionophore, valinomycin followed by increasing concentrations of extracellular K+. Each depolarizing stimulus evoked a fast and transitory increase in the [Ca2+]i. We then calculated seven different kinetic parameters of such responses: basal Ca2+ level, increase and decrease velocity, maximum Ca2+ reached, response durability, and area under the curve (AUC). The basal Ca2+ level reached after depolarizing stimuli correlated negatively ($R = -0.64$, $p = 0.03$) with the conventional IVF fertilization ratio (number of zygotes/total number of mature oocytes) when the Vm was clamped either to –64 and –46 mV. A negative and significant correlation ($R = -0.76$, $p = 0.006$) was seen for the AUC analysis at –64 mV. No relevant correlations were found in the ICSI samples.

Limitations, reasons for caution: This is an in vitro study, and caution must be taken when extrapolating these results in vivo. The preliminary nature of the results implies a necessity to increase the number of analyzed semen samples (in progress).

Wider implications of the findings: Further research into the molecular regulation of the CatSper channel could offer promising alternatives for clinicians to appropriately choose between IVF and ICSI for each couple. This protocol is fast and simple to perform in a laboratory equipped with a flow cytometer or any fluorescence-based reader.

P-097 Embryological and Clinical Outcomes of Microdissection testicular sperm extraction combined with Intracytoplasmic sperm injection (microTESE-ICSI) in patients with and without Klinefelter syndrome

T. Nguyen Phan[1], T.T.V. Lại[1], H.V. Đinh[2], T.Y. Đoàn[1], T.H. Nguyễn[1], T.T.H. Lê[3], M.Đ. Nguyễn[1]

[1]Andrology and Fertility Hospital of Hanoi, Assisted Reproductive IVF Lab, Hanoi, Vietnam
[2]Andrology and Fertility Hospital of Hanoi, Andrology Department, Hanoi, Vietnam
[3]Andrology and Fertility Hospital of Hanoi, Assisted Reproduction Department, Hanoi, Vietnam

Study question: This retrospective study aims to identify the embryo development and clinical outcomes in non-mosaic Klinefelter syndrome patients treated with microTESE-ICSI

Summary answer: Non-mosaic Klinefelter patients can retrieve their sperm using microTESE and can have their biological offsprings by combining microTESE with ICSI

What is known already: Klinefelter syndrome patients are classified into two main groups, namely non-mosaic Klinefelter (47, XXY) and mosaic Klinefelter (46, XY/47, XXY). To retrieve sperm from non-mosaic Klinefelter, microTESE is a crucial treatment that yields a successful rate of approximately 50%. Recent research reports that microTESE-ICSI is a treatment regime that brings a higher *in-vitro* fertilization (IVF) success rate for those with non-mosaic Klinefelter syndrome. However, most of the previous studies on this group focuses on sperm retrieval rate and male factors. Few studies have reported embryo development and clinical outcomes, especially, under the adjustment for female partner's age and oocyte quantity

Study design, size, duration: This retrospective study was conducted to evaluate spermatozoa retrieval, embryo development, and clinical outcomes in 931 patients with microTESE treatment at Andrology and Fertility Hospital of Hanoi from 6/2019 to 9/2022. Patients were divided into two groups including 118 patients with non-mosaic Klinefelter syndrome (KS) and 813 patients without Klinefelter syndrome (non-KS).

Participants/materials, setting, methods: In 931 patients, 63 KS and 417 non-KS had spermatozoa retrieved from microTESE were carried out ICSI. In ICSI group, 59 KS and 319 non-KS patients whose partners were under 35 years old were selected to compare embryological and clinical outcomes. Outcomes included fertilization rate, day 3 usable embryo rate, usable blastocyst rate, pregnancy rate (positive beta-hCG test), biochemical pregnancy rate, ongoing pregnancy, and live-birth rate (calculated on the total number of IVF cycles).

Main results and the role of chance: Spermatozoa retrieval rate by microTESE in the KS group was 53.4% (63/118), while this rate in the non-KS group was 51.2% (417/813) ($p > 0.05$). The mean age of female partners was significantly lower in the KS group than in non-KS group (26.6 ± 4.0 vs. 28.0 ± 3.5; $p = 0.006$). The mean of mature oocytes between these two groups was similar (15.7 ± 8.1 vs 14.5 ± 7.2; $p > 0.05$). Fertilization rates in KS and non-KS groups were 62.7% and 65.3%, respectively. Day 3 usable embryo rate (embryo with over 6 blastomeres at day 3) in two groups was not significantly different (69% vs 69.5%, $p > 0.05$). Usable blastocyst rate (embryo quality is over 2BB, Gardner grading system) in the KS group (19.9%,

n = 54) was significantly lower than in non-KS group (41.1%, n = 281) ($p < 0.001$).

Pregnancy rate and biochemical pregnancy rate were 75.9% and 6.9% in KS group (n = 58), respectively. Those rates were 81.5% and 3.2% in non-KS group (n = 313), respectively. There was no significant difference in ongoing pregnancy rate between these two groups (61.1% vs 74.5%; $p > 0.05$). Live-birth rate in the KS group was 43.2% (16/37), while this rate in the non-KS group was 46.5% (67/145).

Limitations, reasons for caution: This research had limitations of a retrospective study. Male hormonal factors and baby health could not be thoroughly measured because of difficulties in contact with patients at the time of the study. Besides, day 3 top-quality embryos were directed to freeze, so usable blastocyst rate was low in this study.

Wider implications of the findings: These data confirmed that microTESE provides opportunities for non-mosaic Klinefelter syndrome patients to retrieve their own sperm. Combination of microTESE and ICSI is an effective treatment regimen that helps these patients to have their own usable embryos and babies.

[4]IRCCS Ospedale Policlinico San Martino and University of Genova, UOC Clinica di Oncologia Medica and Department of Internal Medicine and Medical Sciences DiMI, Genova, Italy

Study question: Does cryopreservation impact on transcriptome of conventional frozen human spermatozoa?

Summary answer: The cryopreservation of human sperm alters pathways important for fertility, although the upregulation of some genes can compensate for the harmful effects of freezing.

What is known already: Sperm cryopreservation is a widely used procedure for storing gametes for later use, for preserving fertility in patients before gonadotoxic treatments or surgery, and for sperm donation programs. The cryopreservation technique can cause damage to sperm through induction of DNA alterations, fragmentation and oxidation, and altered motility, mitochondrial activity and morphology. Transcriptomic alterations have been reported in cryopreserved sperm from various animal species, but no experimental data are available on the effect of cryopreservation on the transcriptome-wide profile of human sperm.

Study design, size, duration: Semen samples were obtained from 20 normospermic men from April to May 2022. Each sample was divided in two aliquots. From one aliquot total RNA was immediately extracted. The second aliquot was slowly cryopreserved and after a week of storage in liquid nitrogen total RNA was extracted. A total of 13 paired RNA samples passed quality control and were analyzed after randomization into 4 pools, each of 6 patients.

Participants/materials, setting, methods: The men who participated in this study had a median age of 35.0 years (range: 29.0-46.0). RNA was extracted by miRNeasy Micro Kit (Qiagen), analyzed by High Sensitivity RNA on 2200 Tape Station system (Agilent), amplified by Ovation Pico WTA SystemV2 (Nugen), labeled and hybridized on GE 4x44K v2 microarrays (Agilent). The paired Significance Analysis of Microarray (SAM) was performed using the limma hgug4112a.db and samr packages in R/BioConductor.

Main results and the role of chance: The expression profiles of cryopreserved sperm significantly differed from those of fresh sperm in 219 down-regulated and 28 up-regulated unique transcripts. The gene ontology analysis disclosed that cryopreservation downregulates genes involved in sperm motility by the mitochondria function (*CABS1*, *SPATA19*) and the correct organization of the sperm midpiece and flagellum cytoskeleton (*ACTL7A*, *AKAP4*, *C9ORF24*, *CAPZB*, *CCIN*, *IQCG*, *ODF2*, *SPATA6*, *SPATA6L*, *TBC1D21*), in fertilization (*ACTL7A*, *AKAP4*, *PLCZ1*, *PRSS37*, *TUBGCP3*), early embryo development (*AGT*, *CLMN*, *DCC*, *DHRS3*, *EGFLAM*, *FAM20A*, *FREM1*, *GPI*, *HEMGN*, *KRTDAP*, *IFT172*, *MICAL2*, *MLF1*, *NF2*, *PGRMC2*, *PHACTR1*, *POPDC3*, *RO60*, *ROBO1*, *RORA*, *SGCA*, *SPRR2D*, *TCF4*, *TNC*, *TNNI3*), oxidant detoxification (*TXNDC29*) and DNA repair (*BRIP1*, *ERCC6*, *TRIP12*), calcium ion binding and homeostasis (*AMY1C*, *ANO1*, *ANO2*, *ASGR1*, *CABS1*, *CPNE9*, *FREM1*, *KCNIP2*, *ITPR3*, *PKD2L1*, *PLCZ1*, *SELENOK*, *SYN3*, *TNNI3*). Upregulated genes were enriched in pathways related to the negative regulation of DNA damage response (*ALOX15B*, *CD74*, *RPL10*, *SNAI1*, *THBS1*), cellular response to calcium ion (*ALOX15B*, *FOSB*, *HLA-DQB1*, *S100A4*, *THBS1*), regulation of transcription (*CD74*, *FOSB*, *HLA-DRB1*, *MAMLD1*, *RASD1*, *RPL10*, *SNAI1*, *TCF15*, *TLE1*), protein stabilization (*CD74*), protein ubiquitination (*BAG1*, *DCAF6*, *ERCC6*, *HERPUD2*, *KLHL7*, *MARCHF8*, *NF2*, *PSMA6*, *RNF133*, *SERGEF*, *TRIP12*, *UBE2DNL*, *UBL3*, *UBQLN3*, *ZNRF3*) and ubiquitin protein ligase binding (*GPI*, *HSPA1L*, *PRKAR2A*, *STX8*).

Limitations, reasons for caution: Data validation in a larger sample cohort and by quantitative PCR would be useful, although we have applied stringent criteria for gene selection (FDR = 0). Further research should be undertaken to experimentally test whether the length of cryostorage can have any effect on the gene expression profile of sperm.

Wider implications of the findings: Specific pathways are deregulated by cryopreservation, in accordance with altered sperm morphology, motility and molecular integrity reported in literature. Functional enrichment analyses also revealed gene expression changes to compensate for the sperm cryoinjury. This finding is noteworthy for safety issue of sperm banking i.e., fertility preservation, gamete donation.

Trial registration number: not applicable

[3]DIANA Lab Department of Computer Science and Biomedical Informatics, University of Thessaly, Lamia, Greece
[4]Genesis Genoma Lab, Genetic Diagnosis Clinical Genetics and Research, Athens, Greece

Study question: Could microRNA dysregulation be an underlying molecular mechanism leading to the observed increased prevalence of cancer in patients with Sertoli-cell only syndrome (SCOS)?

Summary answer: Patients with SCOS are characterized by altered microRNA profiles and dysregulated gene pathways involved in SCOS pathophysiology and in cell-cycle control and therefore in carcinogenesis.

What is known already: Sertoli cell-only syndrome constitutes a histopathological subtype of non-obstructive azoospermia, affecting 26.3–57.8% of azoospermia patients. It is characterized by partial or complete absence of active spermatogenesis due to germ cell aplasia. Except from infertility, SCOS is associated with increased risk of testicular nodules and cancer, rendering research on the topic essential. Despite advances, the underlying molecular mechanisms connecting SCOS with cancer remain unknown. Data

demonstrates that microRNAs could play crucial roles in both SCOS pathophysiology and carcinogenesis. Identifying relevant microRNAs and conducting in-silico analysis on affected pathways may lead to mapping the way forward.

Study design, size, duration: A systematic review was performed in PubMed/Medline and Embase up to April 2022. Only full-length original studies in humans were included. Strict inclusion-exclusion criteria were applied aiming to select studies comparing microRNA profiling between SCOS cases versus men with normal spermatogenesis or men with proven fertility. Following study selection, data on altered microRNA expression patterns were analyzed to underline differences between the abovementioned groups. Subsequently, in-silico functional analysis was performed to compare affected gene pathways.

Participants/materials, setting, methods: The studied population consisted of SCOS cases. Men with normal spermatogenesis or proven fertility served as the control group. Predicted microRNA–target pairs were retrieved from microT-CDS, while a 0.8 cutoff threshold was applied. The GTEx repository was used to identify microRNA-targeted genes in the testis. Annotations derived from Ensembl and miRbase. Gene-set enrichment analysis was performed employing the KEGG-database. Fisher's exact test was performed in R package limma, setting a 0.01 p-value threshold.

Main results and the role of chance: Four studies reported altered microRNA expression profiles in SCOS (n = 45) versus normal spermatogenesis cases or men of proven fertility (n = 16). Functional analysis revealed that six microRNAs, which were downregulated in the SCOS cases, namely hsa-miR-34b-5p, hsa-miR-202-3p, hsa-miR-34c-5p, hsa-miR-449a, hsa-miR-141-3p, and hsa-miR-34b-3p, affected 66 statistically significant gene-targets in the testis. Two pathways were reported to be statistically significantly dysregulated from these microRNAs, namely the ''microRNAs in cancer'' pathway (40 affected genes, p-value = 0.004), and the ''TGF-beta signaling'' pathway (26 affected genes, p-value = 0.01). Furthermore, four microRNAs, namely hsa-miR-10b-5p, hsa-miR-4270, hsa-miR-181c-5p, and hsa-miR-605-3p, reported to be upregulated in the SCOS group. These microRNAs had 108 statistically significant gene-targets in the testis. Three pathways were statistically significantly dysregulated from these microRNAs, namely the ''Herpes simplex virus 1 infection'' pathway (61 affected genes, p-value = 0.01), the ''microRNAs in cancer'' pathway (28 affected genes, p-value = 0.01), and the ''longevity regulating'' pathway (19 affected genes, p-value = 0.01). The molecular role of the affected gene pathways in proper cell-cycle regulation and germ cell differentiation is herein underlined as critical. In the disrupted testicular microenvironment of the SCOS cases these disrupted genes may act as inducers of carcinogenic mechanisms.

Limitations, reasons for caution: The main limitation is the small number of the included studies and the small number of participants investigated per study, especially with regards to the control group. Moreover, the observed heterogeneity among the studies regarding the molecular tools employed for the microRNA profiling is another reason for caution.

Wider implications of the findings: Our data suggest that the dysregulation of microRNAs affecting several gene pathways that control cell-cycle and differentiation may lead to increased cancer risk in SCOS cases. Further studies employing our findings as a starting point will indicate whether microRNA profiling can serve as an effective evaluation tool for cancer predisposition.

Study question: Does male sterilisation with vasectomy induce changes in the seminal microbiome composition?

Summary answer: Human semen harbours an enriched microbial community and the seminal microbiome composition significantly differed in semen samples from the same men before and after vasectomy.

What is known already: The semen harbours a polymicrobial community, where *Lactobacillus*, *Corynebacterium*, *Staphylococcus*, *Prevotella*, and *Finegoldia* are common. The origin of the seminal microbiome, however, has not yet been established. One-third of the seminal microbes originate from the urethra, whereas a considerable part could originate from the upper genital tract. Similarly, male reproductive organs, such as prostate, seminal vesicles, and testicles contain its own microbiome. Recent pioneering studies analysing a total of 18 men indicates that vasectomy procedure alters the seminal microbiome, suggesting a testicular or epididymal microbial origin.

Study design, size, duration: This cohort study included 36 men (age = 40.4 ± 5.2 years, BMI = 26.2 ± 3.9 kg/m^2) who were planning to undergo vasectomy at the University Hospital from February to June 2021 and volunteered to donate semen samples before vasectomy and 3 months after the procedure. The study was approved by the Ethics Committee of Investigación Biomédica de Andalucia.

Participants/materials, setting, methods: Samples were collected after washing the penis with soap and water, and after urinating. Semen was obtained by masturbation (3-5 days of abstinence) before the vasectomy and 3 months post-vasectomy. The seminal microbiome was analysed by sequencing the V4 hypervariable region of the 16S rRNA gene (Illumina MiSeq). Raw sequences were pre-processed and taxonomy assigned using *Quantitative Insights Into Microbial Ecology version 2* (QIIME2). Bacterial diversity and abundance analyses were performed in R software.

Main results and the role of chance: Fifty-six bacterial genera were detected in the semen samples, where *Campylobacter*, *Finegoldia*, *Ezakiella*, *Streptococcus*, *Staphylococcus*, *Corynebacterium*, *Peptoniphilus*, and *Anaerococcus* prevailed (each genus with a relative abundance ≥5%). Post-vasectomy semen samples had significantly higher alpha diversity (observed richness diversity Wilcoxon signed-rank p-value = 0.035) and markedly increased abundance of genera *Porphyromonas*, *Finegoldia*, and *Anaerococcus*, while *Acetobacter* genus was reduced when compared with semen samples collected before the vasectomy procedure (FDR p-value<0.05). Beta diversity analysis indicated a significant microbial dissimilarity between seminal samples collected before and after vasectomy (weighted and unweighted PERMANOVA p-value = 0.001).

Limitations, reasons for caution: This study did not include urine samples, which do share around 30% of the microorganisms with semen. Therefore, in the next step we aim to integrate urine samples into the analysis.

Wider implications of the findings: Male sterilisation with vasectomy gave rise to fluctuations in the seminal microbiome composition and abundance. Our study findings provide new insight into the origin of seminal microbes, indicating that some accompanying bacteria could originate already from the testicular environment and their changes could entail microbial unbalance in semen.

P-101 A comprehensive profile of cell-free RNAs in seminal plasma reveals their noninvasive potential in male infertility

Q. Zhou[1], F. Yue[2], Z. Liu[1], Y. Jiang[2], Y. Liu[1,3], Y. Wang[1], Y. Qin[1,3], C. Hu[1], R. Liu[2], W.J. Wang[1]

[2]*Center of Reproductive Medicine and Center of Prenatal Diagnosisthe, First Hospital- Jilin University, Changchun, China*
[3]*College of Life Sciences, University of Chinese Academy of Sciences, Beijing, China*

Study question: Could the cell-free RNAs (cfRNAs) in seminal plasma be associated with male infertility and used as clinical biomarkers?

Summary answer: CfRNAs in seminal plasma show different patterns in men with infertility and could serve as diagnostic and predictive factors in male infertility.

What is known already: Seminal plasma is a biological fluid containing large amounts of tissue-specific components secreted by organs of the male reproductive system. Thus, seminal plasma has great potential as a clinical sample for biomarker discovery and noninvasive diagnostics of male reproductive disorders. Several metabolites, metal ions, proteins and nucleotides are associated with semen quality and could be predictive factors of azoospermia forms and subtypes. However, the comprehensive transcriptome of cfRNAs in seminal plasma and their clinical value is not clear.

Study design, size, duration: We applied a previously developed library method of polyadenylation ligation-mediated sequencing (PALM-Seq) to capture and sequence the cfRNAs of seminal plasma from adult men, including 129 patients with asthenozoospermia, 101 patients with oligozoospermia, 102 patients with azoospermia (obstructive and nonobstructive azoospermia) and 107 healthy individuals.

Participants/materials, setting, methods: We performed PALM-Seq on the seminal plasma of recruited individuals and comprehensively profiled cfRNAs including miRNA, tRNA, piRNA, lncRNA and mRNA. In addition, we followed up the clinical outcome of assisted reproductive technology (ART) during reproductive therapy.

Main results and the role of chance: Hundreds of miRNA and tRNA could be detected in all samples. Unlike other body biofluids, we defined a large amount of piRNA in seminal plasma since piRNA is highly expressed in germ cells. Besides, the piRNA showed a group-specific pattern in men with infertility, especially in patients with azoospermia. Differentially abundant mRNA in patients with asthenozoospermia, oligozoospermia and azoospermia were mainly involved in regulating mononuclear cell migration, thermogenesis and germ cell development, respectively. The abundance of seminal plasma cfRNAs was associated with parameters of semen quality, as well as sperm DNA fragmentation. At last, using the collected omics data and machine learning models, we could accurately classify the subtypes of azoospermia and successfully predict the ART outcome before treatment.

Limitations, reasons for caution: We only recruited a limited number of individuals in this research and more studies focused on the ART outcome are needed.

Wider implications of the findings: We comprehensively characterized kinds of cfRNAs in seminal plasma for the first time and revealed changes in men with infertility. Our results contribute a new insight into understanding the mechanism of male infertility. Our findings could provide noninvasive diagnostics before invasive biopsies and help to improve the treatment of infertility.

P-102 Inhibition of RANKL increases the number of motile sperm in a subgroup of infertile men

R. Holt[1], L. Mortensen[1], A. Juul[1], M. Blomberg Jensen[1]

[1]*Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction - Rigshospitalet, Copenhagen, Denmark*

Study question: Does inhibition of RANKL increase semen quality in infertile men?

Summary answer: Overall, inhibition of RANKL (Denosumab) did not affect semen quality. However, in a subgroup of men with high serum AMH sperm production was significantly increased.

What is known already: Currently, there is no treatment available for male infertility, but studies in animal and preclinical human data have suggested a role for RANKL in male reproduction.

Study design, size, duration: A single-center, double-blinded, randomized clinical trial in 100 infertile men randomly assigned (1:1) to s.c. injection with 60 mg/mL Denosumab *or* s.c. saline injection 1 mL (0.9%) (placebo). The primary endpoint was changes in semen production, though the study was designed as an explorative study, with the aim of investigating the profile of which infertile men who would have a beneficial treatment outcome of Denosumab.

Participants/materials, setting, methods: All participants were infertile men referred to our andrological clinic due to impaired semen quality. Blood and semen samples were collected at baseline and after one and two cycles of spermatogenesis on day 80 and day 160, respectively.

Main results and the role of chance: There were no differences in semen quality or reproductive hormones at day 80 or day 160 between men treated with Denosumab or placebo. However, men with a serum AMH $\geq$ 40 pmol/L had a significant increase in total motile sperm (143% (SD 116%); $p = 0.011$), progressive motile sperm (133% (SD 100%); $p = 0.039$) and a borderline increase in sperm concentration (64% (SD 95%); $p = 0.056$) at day 80 compared to baseline. Further stratifying men according to both serum AMH ($\geq$ 40 pmol/L) and serum RANKL (highest 50%), showed a significantly higher increase in sperm concentration (107% (SD 111%) vs. -8% (SD 68%); $p = 0.009$), total motile sperm (256% (SD 270%) vs. 31% (SD 125%); $p = 0.039$) and progressive motile sperm (191% (SD 194%) vs. 18% (SD 134%) $p = 0.013$) at day 80 in men treated with Denosumab compared to placebo treated men. Furthermore, serum FSH (-28% (SD 33%) vs. 0%, (SD 22%); $p = 0.041$) and serum LH (-29% (SD 28%) vs. 20% (SD 51%), $p = 0.048$) were significantly lower and testosterone/LH ratio (50% (SD 51%) vs. -7% (SD 43%); $p = 0.024$) significantly higher at day 80 in men treated with Denosumab compared to placebo treatment.

Limitations, reasons for caution: This is a report from a randomized clinical trial, with an explorative design. Randomized clinical trials in a predefined group of infertile men with high serum AMH, are needed to explore if inhibition of RANKL improves semen quality and pregnancy rate in infertile couples with male factor infertility.

Wider implications of the findings: The increase in sperm production after Denosumab treatment in infertile men with preserved Sertoli cell function needs to be validated, in a trial selecting men based on serum AMH. Ultimately, Denosumab may be a potential breakthrough in treating male infertility at least in some infertile men with high serum AMH.

P-103 Three-dimensional oviductal organoid model to study spermatozoa-oviduct interaction in humans

X. Tian[1,2], P.C.N. Chiu[1], C.L. Lee[1]

[1]*The University of HongKong, Obstetrics and gynaecology, Hong Kong, China*
[2]*The University of Hong Kong-Shenzhen Hospital, Shenzhen Key Laboratory of Fertility Regulation, Shenzhen, China*

Study question: Is it possible to establish an *in vitro* model that recapitulating human oviduct to investigate sperm-oviduct interaction

Summary answer: Three-dimensional (3D) oviductal organoid model was established from either primary human oviductal tissues or immortalized human OE-E6/67 cell line, based on our protocol.

What is known already: The sperm reservoir in oviduct is formed to maintain the fertilizing capacity of spermatozoa until ovulation by the binding of sperm to the epithelial lining of the oviduct, which is also significant to select

sperm with normal chromatin structure and superior fertilization ability. The regulation and mechanism of sperm reservoir formation in human is still unknown, mainly due to the ethical issue and technical difficulty in obtaining enough human oviduct. We previously demonstrated that sperm fucosyltransferase-5 (sFUT5), a carbohydrate-binding protein on spermatozoa, is responsible for spermatozoa-oviduct interaction in humans.

Study design, size, duration: Human oviductal epithelial cell line immortalized by HPV 16 E6/E7 open reading frame by retroviral expression system was employed to establish the co-culture model. Fresh human samples (human spermatozoa,N = 30; 1-2 cm primary oviductal tissue,N = 15) were collected in hospital with signed consent. Fluorescent pre-labelled sperm were co-cultured with organoids for 2 hours. At least three replicates were conducted for each assay.

Participants/materials, setting, methods: Morphological characterization and markers expressions of the organoid were determined by immunohistochemistry and confocal microscopy analysis. The sperm binding capacity of the oviductal organoid was studied by co-culture system. Sperm chromatin structure of the organoid-bound sperm was assessed by flow cytometry-based TUNEL assay. Affinity chromatography followed by nano-liquid chromatography–mass spectrometry was used to identify the sFUT5-binding proteins on ovidutal epithelial cells (OECs) and their expressions on OECs were validated by immunostaining/flow cytometry.

Main results and the role of chance: The organoid exhibited a hollow structure surrounded by a single layer of OECs. Immunohistochemistry analysis revealed the high expressions of epithelial marker E-cadherin (basolateral membrane), secretory marker pair-box 8 (PAX8) and proliferative marker Ki67. Expression of ciliated cell marker, acetylated tubulin (AcTUB) can also be detected. The modification of culture environment successfully reversed the OEC organoids polarity as demonstrated by immunostaining using antibodies against ZO-1 (apical marker) and E-cadherin (basolateral marker), making the organoid accessible during the co-culture. These apical-out OEC organoids have significantly higher sperm binding capacities than their basal-out counterparts. Furthermore, OEC organoid-bound spermatozoa possessed more intact DNA than the unbound spermatozoa. The results indicate the relevance of using OEC organoid-spermatozoa co-culture model as a tool to assess spermatozoa-oviduct interaction in humans. By using immuno-affinity chromatography and mass spectrometry analysis, cell adhesion molecule 4 (CADM4) was then identified as a potential sFUT5-interacting protein on OECs. This result was further supported by flow cytometry and immunofluorescent staining. 3-D oviductal organoid model demonstrates profound potential for *in vitro* investigation of human oviduct physiology.

Limitations, reasons for caution: Our 3D model may not fully represent the entire cellular complexity and tubular architecture of the oviductal epithelium. Further investigation on the sperm morphology and DNA integrity and analysis on organoid transcriptome will enhance our understanding on oviduct in human reproduction.

Wider implications of the findings: The results from co-culture may give a clue to future study on whether oviductal organoid can be applied clinically for functional sperm selection in *in vitro* fertilization. Our apical-out organoid model may also be applied to study tubal ectopic pregnency.

Trial registration number: not applicable

Abstract citation ID: dead093.468
P-104 Impact of Semen Microbiota on the Embryo Quality

E. Panacheva[1], E. Voroshilina[2], E. Kudryavtseva[3]

[1]*Medical Center "Garmonia", Department of ART, Yekaterinburg, Russia C.I.S*
[2]*Ural State Medical University, Microbiology- Virology and Immunology, Yekaterinburg, Russia C.I.S*
[3]*Ural State Medical University, Central Research Laboratory, Yekaterinburg, Russia C.I.S*

Study question: Is there a relationship between the microbiota composition of semen samples used for assisted reproductive technologies (ART) and quality of embryos?

Summary answer: The obligate anaerobes prevalence in semen microbiota was associated with reduced embryo quality in patients with astenozoospermia, but no difference was found for normozoospermic samples.

What is known already: The success of the ART depends on a number of factors, including embryo quality. The viability of IVF embryo could be affected by various environmental factors, including contamination with semen microbiota. Semen is not sterile, and even processed it may contain some bacteria, which may colonize culture dishes with oocytes and embryos. It was shown that the presence of bacteria might alter the sperm quality and the contamination of embryo culture dishes with bacteria was associated with poor quality of the developing embryos.

Study design, size, duration: 126 infertile couples attending the "Garmonia" Medical Center (Yekaterinburg, Russia) for IVF in 2020-2021, were included in the study. Depending on the spermiogram results, they were divided into two groups Group 1 (n = 51) — asthenozoospermia, Group 2 (n = 75) — normospermia.

Participants/materials, setting, methods: Semen microbiota was analyzed using RT-PCR kit Androflor (DNA-Technology, Russia). Cluster analysis was performed for 78 samples with the total bacterial load (TBL) of at least 10^3 GE/ml (asthenozoospermia = 31, normozoospermia = 47). Cluster analysis was conducted using the k-means++ algorithm, scikit-learn. The blastocyst development rate (BDR), as the proportion of 2PN zygotes, was determined on day 5 after injection. BDR $\geq$ 40% was considered satisfactory, BDR < 40% - unsatisfactory.

Main results and the role of chance: When analyzing semen microbiota, 8 stable clusters were distinguished. Cluster 1 was lactobacilli-dominated, Cluster 2 and 3 - Gram-positive facultative anaerobes dominated with prevalence of *Corynebacterium spp.* and *Streptococcus spp.* respectively; Cluster 4 – *Enterobacteriaceae/Enterococcus spp*-dominated,; Cluster 5, 6 - obligate anaerobes dominated with prevalence of *Bacteroides spp./Porphyromonas spp./Prevotella spp.* or *Peptostreptococcus spp./Parvimonas spp.*, respectively. Cluster 7 was formed by mixed obligate anaerobes (MOA); Cluster 8 - by *Mycoplasmae*.

There was no difference in detection rate of individual clusters in samples with normospermia and asthenozoospermia.

Depending on their BDR each group were divided into subgroups: Subgroup 1A (n = 25) with BDR $\geq$ 40%, Subgroup 1B (n = 26) with BDR < 40%; Subgroup 2A (n = 38) with BDR $\geq$ 40%, Subgroup 2B (n = 37) with BDR < 40%.

The detection rate of different microbiota clusters in Subgroups 2A and 2B (normospermia samples) was almost similar.

In asthenozoospermia samples the lower embryo quality (Subgroup 1B) was associated with higher prevalence of Cluster 7 (53.8%) comparing to those of Subgroup 1A (16.0%), $p < 0.001$. Cluster 1 was detected more often in Subgroup 1A (20.0%) than in Subgroup 1B (7.8%), but $p > 0.05$. TBL > 10^3 GE/ml was present in 52% of Subgroup 1A samples and in 69.2% of Subgroup 1B samples.

Limitations, reasons for caution: Cluster analysis was not conducted for the samples with TBL lower than 10^3 GE/ml, since their results were incompatible with the data received for the negative control samples.

Wider implications of the findings: Further research could determine the significance of the described bacterial clusters in semen with other pathologies. Establishing the relationship between the characteristics of semen microbiota and poor embryo quality might allow the development of new algorithms for treating patients with reproductive disorders, depending on the composition of semen microbiota.

P-105 The Reliability of Sperm Chromatin Dispersion (SCD) Test to Predict Assisted Reproductive Technology (ART) Treatments Outcomes -A Systematic Review and Meta-Analysis

R. Sawaid kaiyal[1], K. Kumar Karna[2], R. Cannarella[3], K. Shinnosuke[4], L. Scott[5], S.C. Vij[5]

[1]*Bar-Ilan University Azrieli Faculty of Medicine- Israel - Cleveland Clinic Foundation-Ohio- US, IVF unit- Urology Department, judeide-maker, Israel*
[2]*University of Massachusetts Chan- Medical School-, Molecular- Cell and Cancer Biology, Worcester- Massachusetts, U.S.A.*
[3]*Clevelend Clinic Foundation, Urology, Clevelnad- Ohio, U.S.A.*
[4]*Cleveland Clinic Foundation, Urology, Cleveland. Ohio, U.S.A.*
[5]*Cleveland clinic foundation, Urology, Clevelnad- Ohio, U.S.A.*

Study question: Is the sperm chromatin dispersion (SCD) test reliable for predicting reproductive technology (ART) treatment outcomes?

Summary answer: Assessment of DNA fragmentation using the SCD test failed to predict pregnancy or live births rates.

What is known already: The detrimental effect of high DNA fragmentation on semen quality, fertility, and poor ART outcomes has been well-studied in recent years. Still, it remains contentious. Several techniques can detect sperm DNA fragmentation, such as TUNEL, comet assay, and SCSA. Although these techniques have been implemented in many andrology laboratories, they remain complex, time-consuming, and expensive. On the other hand, the SCD test indirectly estimates the DNA fragmentation level by manually quantifying the number of halos representing nuclear dispersion after sperm lysis and acid denaturation. While the SCD test is commonly used, it remains subjected to bias and high variability.

Study design, size, duration: Systematic review and meta-analysis.

A PRISMA-guided literature search in the English language was performed in January 2021 using PubMed/MEDLINE, Scopus, and Google scholar.

We looked for rates of fertilization, cleavage rate embryos, implantation, clinical pregnancy, miscarriage, and live birth.

MedCalc software using the random effects model was used, Sensitivity analysis was conducted to examine heterogeneity and the robustness of the results.

Participants/materials, setting, methods: After duplicate removal, 179 abstracts were assessed for eligibility, and 55 full-text articles were screened. Forty-one articles were included in the qualitative syntheses, and 16 were included in the quantitative synthesis, representing 6989 participants.

Main results and the role of chance: No significant difference was identified between the group with high SDF vs. low SDF regarding fertilization (SMD −0.334, 95% CI −0.695, 0.027, $p = 0.07$), clinical pregnancy (OR 0.901, 95% CI 0.719, 1.130, $p = 0.367$), miscarriage (OR 0.901, 95% CI 0.719, 1.130, $p = 0.367$) and live birth (OR 1.105, 95% CI 0.627, 1.946, $p = 0.730$) rates.

The rates of cleavage stage embryos (SMD -1.153, 95% CI -2.113, −0.194, $p = 0.019$) and implantation (OR 0.472, 95% CI 0.303, 0.737, $p = 0.001$) were significantly lower in the group with high SDF vs. low SDF.

Limitations, reasons for caution: A high index of heterogeneity and publication bias was reported regarding fertilization (I2 = 93.23%, Egger's test: intercept -5.29866, 95% CI -10.41, −0.19, $p = 0.02$) and cleavage-stage embryos(I2 = 98.49%, Egger's test: intercept -14.02395, 95% CI -27.47, −0.57, $p = 0.02$)

Wider implications of the findings: Assessment of DNA fragmentation using the SCD test failed to predict pregnancy or live births. As the goal of ART is live birth, clinicians should consider the limited yield of this assay to predict the likelihood of live birth.

P-106 The inhibition of sperm SIRT1 enhances fertilization and modifies subsequent embryonic epigenetic quality

M. Iniesta-Cuerda[1,2], H. Řimnáčová[3], D. Krapf[4], J. Nevoral[3]

[1]*Biotechnology of Animal and Human Reproduction TechnoSperm- Unit of Cell Biology- Department of Biology- Faculty of Sciences- Institute of Food and Agricultural Technology- University of Girona, Department of Biology, Gerona, Spain*
[2]*Unit of Cell Biology- Faculty of Sciences- University of Girona- Girona- Spain, Department of Biology, Girona, Spain*

[4]*Instituto de Biología Molecular y Celular de Rosario IBR- Consejo Nacional de Investigaciones Científicas y Técnicas CONICET-, Universidad Nacional de Rosario UNR, Rosario, Argentina*

Study question: Is SIRT1 present in sperm and thus involved in fertilization and/or sperm epigenetic code? Do the SIRT1-driven epigenetic marks be transmitted to the progeny?

Summary answer: SIRT1 localized at the sperm head and influences fertilization and sperm epigenetic code via its deacetylation activity. SIRT1-modulated epigenome is transmitted to zygotes and blastocysts.

What is known already: The addition or removal of acetyl group from lysine residua (i.e. acetylation) post-translationally modulates proteins through the action of acetylases and deacetylases, respectively. SIRT1 (also Sirtuin 1) is capable to deacetylate a number of proteins, including histones, with roles in male reproduction. Testicular SIRT1 deficit leads to subfertility and increases number of abnormal and immotile spermatozoa that fail to fertilize. However, neither sperm SIRT1 presence nor its function has been investigated despite the significance of acetylation in the events around fertilization. Moreover, the epigenetic mode of action of sperm SIRT1 highlights its relevance for the success of the pre-implantation embryo.

Study design, size, duration: Mouse sperm of 14-18-weeks-old males of CD-1 x C57Bl6 hybrid strain were isolated from the epididymis. Sperm were incubated under capacitating conditions in presence of sirtinol (5 μM), a selective SIRT1 inhibitor, or the vehicle (0.1% v/v DMSO) for 1 h in 37 °C and 5% CO_2.

Participants/materials, setting, methods: Motility and acrosome reaction was evaluated as previously stated (Ritagliati et al., 2018). Moreover, sperm proteins were extracted into RIPA-buffer and acetylated proteins were depicted by western blot. Finally, *in vitro* fertilization and embryo culture were performed. Above parameters defining IVF outcomes (i.e., fertilization, cleavage, and blastocyst rate), immunocytochemistry of acetylated histone 4 in the 16th residua of lysine (H4K16) in zygotes and blastocyst was quantified.

Main results and the role of chance: SIRT1 was localized in the sperm head, apparently at the perinuclear theca and perforatorium. Inhibition of SIRT1 leads to the increase of lysine acetylation (2.28 *vs* 1, fold change values) and hyperactivation (16.55 ± 0.79 *vs* 10.84 ± 0.79 %sperm), the enhanced motility that facilitates sperm to penetrate the oocyte, as well as the acrosome reaction (28.69 ± 0.41 *vs* 17.98 ± 0.41 %sperm). Subsequently, these spermatozoa were able to better fertilize oocytes *in vitro* (90.5 ± 7.21 *vs* 66.25 ± 7.21, %). Interestingly, zygotes derived from sirtinol-pre-treated spermatozoa developed to 2-cell embryos at a higher rate than those fertilized by untreated spermatozoa (79.33 ± 7.21 *vs* 67.00 ± 7.21, %). Moreover, we observed significant hyperacetylation of H4K16 in the male pronuclei of zygotes and embryos derived from sirtinol-treated sperm (8.19 ± 1.02 *vs* 6.10 ± 2.09 and 45.55 ± 13.96 *vs* 27.62 ± 13.96, integrated density of the signals, respectively).

Limitations, reasons for caution: Although acetylation of H4K16 was accumulated in male pronuclei, we do not know which subset of genes was affected. Therefore, we only can assure that SIRT1-driven epigenetic marks are transmitted to the offspring, but their consequences should be further elucidated. For knowledge transfer to humans, a verification study is required.

Wider implications of the findings: the reduction in testicular SIRT1 expression is an age-related phenomenon. Therefore, our results support SIRT1 as the basis for new interventions against age-related male infertility. Moreover, due to the high reactivity of SIRT1 to its inactivation, SIRT1

becomes a target to pharmacologically enhance sperm fertilization ability in assisted reproductive techniques.

Trial registration number: Animal procedures were conducted in accordance with Act No. 246/1992 Coll. on the Protection of Animals Against Cruelty under the supervision of the Animal Welfare Committee of the Ministry of Education, Youth and Sports of the Czech Republic, approval ID MSMT-11925/2016-3.

P-107 MICROFLUIDIC SPERM SEXING: An XLD (X-linked Disorder) model for preventing genetic disorders in newborns

O. Adenmosun[1]

[1]*Florida Atlantic University, Biological Sciences, Davie, U.S.A.*

Study question: Can sperm sexing based on unique surface membrane markers – enable genotypic sperm sorting by allosomal content to prevent certain X-linked disorders in newborns?

Summary answer: In an X-Linked-Disorder prevention model, we utilized a microfluidic device functionalized with H-Y monoclonal antibodies attached to magnetic beads to enrich Y-chromosome bearing sperm sorts.

What is known already: About 4% of newborns are at risk of being born with an X-linked disease such as Fragile X Syndrome. The current clinically approved mitigation plan for preventing such genetic disorders is to consider Preimplantation Genetic Testing for Monogenetic diseases (PGT-M) which involves an invasive microsurgical procedure on fragile embryos. To minimize this invasiveness, we proposed a less invasive microsurgical exclusion approach to prevent such genetic disorders by genotypically sorting sperm cells that can be used for IUI/IVF/ICSI – with microfluidics – using their allosomal characteristics.

Study design, size, duration: Semen samples purchased from FairFax Cryobank from anonymous donors were used in immuno-magnetic microfluidic sorting protocols with the use of phycoerythrin (PE) binding Tetrameric Antibody Complexes (TAC) coupled with magnetic beads to tag H-Y monoclonal antibody (mab) binding activities on the sperm surface membrane.

Participants/materials, setting, methods: Immuno-magnetic sorting was conducted with specially fabricated microfluidic-sperm-sorting (MSS) chips. Sort yield and purities of positively selected sperm populations were assessed by flow-cytometry, immunofluorescence, fluorescent-in-situ-hybridization (FISH) and by quantitative-PCR (qPCR – Cq & Tm). Quantitative experiments were run in triplicates and the results were expressed as absolute means for comparison between paired variables. Statistical analyses were performed using Student's t-test and a p-value of less than 0.05 was considered to be statistically significant.

Main results and the role of chance: For the assessment of H-Y sperm sorts, our preliminary data showed that flow cytometry was able to confirm the positive sperm selection (which were mostly Y-chromosome bearing sperm cells) in a sperm genotyping protocol – initially utilizing immuno-magnetic sort tubes prior to flowing through microfluidic chips. Both immuno-magnetic sort tubes and the microfluidic chips were able to optimally confirm from qPCR-Cq means – the negative selection – being the X-chromosome bearing sperm that may have been largely unselected by the H-Y-mab. Values for Cq means compared under H-Y-qPCR data sets were statistically significant with a p value of 0.000023 (p values is significant at < 0.05).

Our study was able to elucidate a potential less invasive clinical application of genotypically sorting sperm cells with mab-functionalized microfluidic chips for an XLD-model. Molecular down stream applications like flow cytometry may therefore be utilized to experimentally confirm sort purities of positively selected sperm populations (with H-Y markers) – based on the utility of the SMCX and SMCY gene in the X and Y sperm chromosome bearing sperm cells respectively.

Limitations, reasons for caution: Physiological effect of magnetic fields of varying tesla or gauss strengths on sperm selected with immuno-magnetic beads may warrant further safety studies prior to actual clinical applications. Optimal selection results may be achieved with the use of freshly collected normospermic rather than frozen-thawed samples.

Wider implications of the findings: Although we had de-emphasized the clinical application of the microfluidic sperm sexing protocol for legitimate use in sex selection and gender balancing, this study design was solely focused on adapting a less invasive method of preventing X-linked genetic disorders with the potential exclusion of microsurgical procedures leading to PGT-M.

P-108 Does DNA Fragmentation.level significantly impact clinical outcomes in patients undertaking Assisted Reproduction with using donor oocytes?

A. McNally[1], **C. Harrity**[1], **K. Marron**[2]

[1]*Rotunda Hospital, Obstetrics and Gynaecology, Dublin, Ireland*
[2]*Enfer Laboratory, Biomedical Science, Naas, Ireland*

Study question: Does an abnormal Sperm DNA Fragmentation Index significantly impact clinical outcomes in patients undergoing Assisted Reproduction with ICSI using donor oocytes?

Summary answer: No statistical difference was seen in pregnancy or miscarriage rates between high or low DNA fragmentation indexes with oocyte donation cycles using intracytoplasmic sperm injection.

What is known already: High levels of sperm DNA fragmentation are proposed to have an adverse impact on reproduction. While subject to debate, generally accepted ranges of $> 30\%$ considered high and associated with poorer outcomes, with levels $< 15\%$ considered normal. Impact in the intermediate range if 15-30% is less understood. Potential interventions for elevated DFI include ICSI, lifestyle changes, antioxidant therapy or more controversially TESE. It is thought that high quality oocytes have the potential to repair sperm DNA damage- thus the use of younger donors with higher fertility in oocyte donation cycles may improve outcome and overcome a high DFI.

Study design, size, duration: A retrospective cohort analysis was performed on our database of donor oocyte FET treatment between January 2016 and December 2020, with 1370 cycles identified Screening to identify those couples where pre- treatment sperm DFI was performed as part of the treatment workup, and DFI was analysed in 9% of these cycle ($n = 124$). Clinical outcomes were recorded including positive HCG, clinical pregnancy rate, miscarriage rate and ongoing pregnancy rate at 12/40 gestation, and compared between groups.

Participants/materials, setting, methods: Oocyte donation cycles with baseline Sperm DFI measurements in a tertiary academic centre were identified. Donor treatments were chosen to reduce the impact of female factor variation on results. 49 cases had normal DFI($< 15\%$), and were compared to 21 patients in the high group (> 30). 54 patients were on the intermediate range (15-30%) and were excluded from the analysis. Pregnancy and miscarriage rates were compared between high and low groups to assess impact of DFI.

Main results and the role of chance: Elevated DFI has been proposed to have an abnormal impact on assisted reproduction outcomes. Other studies have suggested that ICSI may compensate for this, or that healthy oocytes may be able to negate any detrimental impact from the sperm. With autologous gamete treatments, large variations in the expected prognosis are due to female characteristics such as age, ovarian reserve or gynaecological disorders such as endometriosis or PCOS. This use of younger egg donors with normal AMH and the exclusion of any identifiable pelvic abnormality allows for some standardisation of the female cohort, therefore allowing a more direct assessment of the impact of any male factor abnormality on the outcome.

Positive HCG rates per embryo transfer were the same between DFI groups.

Normal 53.1% (26/49) vs High 47.65% (10/21) $p = 0.68$

Similarly there was no difference in Clinical Pregnancy Rates based on DFI level

Normal 44.9% (22/49) vs High 47.7% (10/21) $p = 0.83$

Miscarriage rates per positive HCG test were again not impacted by male sperm DFI:

Normal 30.7% (8/26) vs High 33.3 (3/10) $p = 0.72$

The study data demonstrates that in treatment cycles using a combination of ICSI and good quality oocytes, the clinical outcomes do not appear to be impacted by raised DFI

Limitations, reasons for caution: We previously demonstrated that fertilisation and blastulation rates were unaffected by DFI. The study was limited by a relatively small sample size, as DFI analysis was not routinely measured before treatment. Larger multi-centre studies to increase the study population and statistical power would be useful for confirmation of the findings.

Wider implications of the findings: Our data suggests that biochemical, clinical and ongoing pregnancy rates, and also miscarriage rate, were not adversely impacted by high DFI in donor oocyte cycles.This could be attributed to the ability of a high quality oocyte to repair sperm DNA damage when combined with ICSI for sperm selection and fertilisation.

[4]Hillel Yaffe Medical Center- Hadera- Israel affiliated with Rappaport Faculty of Medicine- Technion-Institute of Technology- Haifa- Israel, IVF Unit- Department of Obstetrics and Gynecology- Hadassah Hospital, Hadera, Israel

Study question: Do the outcomes of frozen embryo transfer cycles differ according to endometrial preparation (EP) with letrozole versus hormone replacement therapy (HRT)?

Summary answer: Letrozole seems to be as effective as HRT preparation in frozen cycles in terms of treatment outcomes.

What is known already: Vitrification improved the survival of vitrified-warmed embryos and increased the number of FET cycles. A common EP strategy for FET includes augmentation of the endometrium using estrogen followed by progesterone supplements. Retrospective studies have shown that using aromatase inhibitors (letrozole) in FET cycles was associated with higher clinical pregnancy and live birth rates, with a lower miscarriage rate, as compared to HRT cycles.

Letrozole maintains regular feedback mechanisms, facilitating normal follicular growth, and promotes single follicle development and ovulation. Moreover, it does not have any negative effects on the endometrium and can improve endometrial receptivity.

Study design, size, duration: This randomized controlled trial was performed in two university-affiliated medical centers.

A total of 170 patients undergoing frozen embryo transfer cycles from June 2018 to June 2021 were eligible.

Participants/materials, setting, methods: Patients were randomized to either letrozole (n = 69) or HRT protocol (n = 101) for EP, using a blocked randomization method. Inclusion criteria were single blastocyst transfer with normal uterine cavity. Exclusion criteria were patients older than 40 years, oocyte donation cycles, or more than 3 previous transfers without a pregnancy. The primary study outcome was percentage of clinical pregnancies, defined as clinical pregnancies/embryo transfers, excluding canceled treatments.

Main results and the role of chance: The characteristics of the study groups were comparable in age, BMI, gravidity, parity, previous treatment history and characteristics of the relevant fresh cycle in which the embryo was frozen. After excluding 5 cancelled treatments in the letrozole group and 2 in the HRT group, the percentage of clinical pregnancies between the letrozole and HRT arms were similar (24 (38.0%) versus 34 (34.6%), respectively, p = 0.67). There was no difference in the percentages of live births (22 (34.9%) versus 28 (28.6%), respectively, p = 0.4) or missed abortions (1 (4.1%) versus 5 (14.7%), p = 0.19). For patients who did not achieve pregnancy in the randomized treatment cycle, we retrospectively examined the outcome of the next treatment cycle with the other EP protocol, when possible. Achievement of a clinical pregnancy was the same for change in treatment for both study groups (7(50%) in the letrozole group and 9(50%) in the HRT group).

Limitations, reasons for caution: Limitations of this study included the heterogeneous study groups. Even though class II ovulation disorders were similar in prevalence in both groups, they included different indications for ART. Pregnancy complications were not evaluated and should be further investigated in a study with a larger sample size.

Wider implications of the findings: Letrozole seems to be as effective as HRT for EP in frozen cycles, with possible advantages of fewer missed abortions and pregnancy complications. Letrozole could be a suitable option for EP, as it is effective and, enables more convenient timing, versus natural FET.

Abstract citation ID: dead093.474
P-110 Effects of embryo culture under atmospheric oxygen concentration on cumulative live birth rate and birth weight

C. Longbin[1]

[1]central south university, basic medicine department, Changsha, China

Study question: The purpose of this study is to compare cumulative live birth rate and perinatal outcomes of embryos cultured in 20% oxygen and 5% oxygen.

Summary answer: Atmospheric oxygen concentration not only affects the quality of embryos, but also affects the cumulative live birth rate and birth weight after embryo transfer.

What is known already: Whether 5% oxygen culture can effectively improve the outcome of embryonic pregnancy is still controversial. There is a lack of scientific data support from a large sample, especially regarding the cumulative live birth outcome as the primary outcome.

Study design, size, duration: This retrospective study included patients who received in vitro fertilization (IVF) treatment with their own first oocyte retrieval cycles from 1 January 2016 through 31 November 2019, with transfer dates limited to 31 November 2020. Our final analytic cohort included 31,566 women.

Participants/materials, setting, methods: Embryos were cultured at 5% or 20% oxygen concentration until the third day for transplantation or freezing. If prolonged culture was required, embryos of both groups were transferred to the incubator with 5% oxygen concentration to the blastocyst stage until transplantation or freezing. Other laboratory and clinical procedures were consistent between the two groups.

Main results and the role of chance: The rate of high-quality embryos in the 5% oxygen group was significantly higher than that in the 20% oxygen group (0.51 ± 0.33 vs 0.49 ± 0.33; β = −0.03; 95%CI, −0.03–−0.02; P < 0.001), while the rate of slow-developing embryos was significantly lower (0.52 ± 0.31 vs 0.56 ± 0.31; β = 0.04; 95%CI, 0.03–0.05; P < 0.001). The cumulative live birth rate was significantly higher in the 5% oxygen group than in the 20% oxygen group (62.4% vs 58.6%; adjusted OR = 0.85; 95%CI, 0.81-0.90). The birth weight and Z score (birthweight corrected for gestational age at birth, gender and parity were significantly lower in the 5% oxygen group than in the 20% oxygen group (birth weight: 3.28 ± 0.48 vs 3.30 ± 0.50, adjusted OR = 0.022, 95%CI, 0.004-0.04; Z score: 0.22 ± 1.01 vs 0.26 ± 1.04, adjusted OR = 0.037, 95%CI, 0.001–0.074). No matter what age group, the cumulative live birth rate, pregnancy rate and good birth outcome of the 5% oxygen concentration group were higher than those of the 20% group, while the proportion of no transferable embryos was lower than those of the 20% group.

Limitations, reasons for caution: Limitations include that oocytes were cultured at 20% oxygen concentration on the fertilization day (D0), and randomly distributed to incubators with different oxygen concentrations until day 1. Because it was a retrospective study, the grouping was not randomized.

Wider implications of the findings: We counted the largest sample data at present, took the cumulative live birth rate as the main outcome indicator, and tracked the perinatal outcome, using reliable data to prove that atmospheric oxygen concentration has serious and long-term irreversible effects on embryonic development.

Trial registration number: not applicable

Abstract citation ID: dead093.475

P-111 External validation of a model for prioritizing day 3 embryos for transfer based on deep learning and time-lapse images

J. Zhu[1], **H. Guoning**[1]

[1]*Chongqing Health Center for Women and Children, Center for Reproductive Medicine, Chongqing, China*

Study question: Could an objective embryo assessment by iDAScore version 2.0 perform as well as a conventional morphological assessment according to the Istanbul consensus report?

Summary answer: iDAScore version 2.0 performed as well or even better than conventional embryo assessment in fresh day 3 embryo transfer cycles.

What is known already: The pregnancy prediction performance of iDAScore version 1.0 has been confirmed in a large cohort study with vitrified-warmed blastocyst transfer, the validation results showed that it performs as well or better than conventional embryo evaluation. iDAScore version 2.0 was developed for transfers on both day 2, day 3 and day 5 transfers, however, the performance of iDAScore version 2.0 has not been verified with independent datasets.

Study design, size, duration: A single-center large cohort retrospective study from an independent validation test was carried out, including 4328 cleavage embryo transfers cycles performed between January 2020 and June 2022.

Participants/materials, setting, methods: The selection of embryos for transfer was based on conventional morphological assessment model according to Istanbul consensus report, and the transferred embryos were retrospectively evaluated by the iDAScore version 2.0 model. The pregnancy prediction performances of the two day 3 embryo assessment models were compared using the area under curve (AUC) for predicting the FHB for all cycles and subgroup analysis(SET and DET; female age <35 and $\geq$ 35 year; number of blastomeres <8c and ≥ 8c).

Main results and the role of chance: The FHB rate in the iDAScore (2.0-3.9) group was lower than in all iDAScore group, iDAScore (4.0-5.9), and (6.0-8.0) groups within the poor, fair and good group. Additionally, for fair and good group, the FHB rate in iDAScore (6.0-8.0) group was higher than that in other iDAScore groups. The AUCs of iDAScore were significantly greater than the conventional morphology assessment, for all cycles (0.62 vs. 0.59, $P < 0.05$), SET cycles (0.63 vs. 0.59, $P < 0.05$) and DET cycles (0.61 vs. 0.59, $P < 0.05$). For the sub-groups of age, the AUC of iDAScore was significantly greater than the conventional morphology assessment in <35 group (0.62 vs. 0.59, $P < 0.05$). However, there was no significant difference between the two assessment model in ≥ 35 group (0.60 vs. 0.58, $P > 0.05$). For the sub-groups of the number of blastomeres, a significantly greater AUC was observed for iDAScore than for conventional morphology assessment, for both the <8c group (0.67 vs. 0.56, $P < 0.05$) and the $\geq$ 8c group (0.58 vs. 0.55, $P < 0.05$).

Limitations, reasons for caution: the limitation of the findings is that all analyzed embryos were selected previously by morphology. Although the conventional morphological assessment is a widely used morphological grading system, it is subjective and susceptible to inter-observer variation.

Wider implications of the findings: iDAScore version 2.0 may be a promising tool for selecting day 3 embryos with the highest likelihood of implantation. A fully automated evaluation system also significantly reduced the time used for embryo selection and eliminates subjectivity.

P-112 Outcome of laser collapsing blastocyst on clinical pregnancy rate

D. Urkimbayeva[1]

[1]*Ecomed clinic, embryology, Astana, Kazakhstan*

Study question: To determine clinical pregnancy rate after laser-induced collapse of blastocyst before cryopreservation

Summary answer: Laser collapse of the blastocyst before cryopreservation increases clinical pregnancy rate regardless of assigned embryo quality group compared to the blastocysts vitrified without laser collapsing

What is known already: Vitrification has been associated with the certain risks to the structure of an embryo due to intracellular ice crystal formation and impaired shrinkage rate. Blastocyst is a large fluid filled cavity requiring additional preparation to reduce the potential risks of damage. Collapsing a blastocyst has been shown to improve survival rate of an embryo following thawing and improve in vitro fertilization (IVF) outcomes including clinical pregnancy and live birth rates

Study design, size, duration: . It is a single-centre retrospective study conducted at a private clinic in Kazakhstan. We analyzed the outcome of IVF treatment following cryopreservation and subsequent frozen embryo transfer of 2959 blastocysts from 1642 women during January 2019-December 2021

Participants/materials, setting, methods: The data on blastocyst cryopreservation technique and IVF treatment outcome was collected from the clinic's electronic database. The blastocysts were divided into two groups based on performed laser collapsing prior to vitrification and further stratified by embryo quality group including excellent, good and fair groups. The primary outcome was clinical pregnancy rate. Laser-assisted collapsing procedure was initiated in August 2020 at the clinic. Thus, all previously vitrified blastocysts served as control group for the study

Main results and the role of chance: 1556 blastocysts from 777 women vitrified following laser collapsing and 1403 blastocysts from 865 women without prior laser collapsing were analyzed in the study. Stratification of blastocysts by the embryo quality were comparable between two groups with more than half of embryos defined as excellent embryo quality group, 54% in collapsed group and 52% in non-collapsed group ($p > 0.05$). Most blastocysts were from women under the age of 35 years old in both study groups. 1 in 4 collapsed blastocysts of the excellent embryo quality group were from women older than 35 years old, whereas non-collapsed group of blastocysts was evenly distributed between embryo quality groups ($p < 0.05$). Clinical pregnancy rate was the highest in the excellent embryo quality group with prior laser collapsing compared to the group without collapsing, 53% vs 43% respectively ($p < 0.001$). Overall, collapsed blastocysts showed higher rate of clinical pregnancy rate in all three embryo quality groups. Despite of changes associated with the COVID-19 pandemic IVF outcomes had not been affected but improved with the use of laser collapsing prior to embryo vitrification

Limitations, reasons for caution: Retrospective design of the study did not provide full baseline information on potential confounders including paternal characteristics and concurrent conditions. Moreover, the study period included the COVID-19 pandemic start which could have affected treatment outcomes

Wider implications of the findings: Collapsing the blastocyst embryo before vitrification should become a routine procedure to improve treatment outcomes of frozen embryo transfer irrespective of woman's age and embryo's quality

Trial registration number: not applicable

Abstract citation ID: dead093.477

P-113 The performance of pregnancy prediction is improved in an updated deep-learning based embryo selection model: A retrospective validation study using 3960 single blastocyst transfer cycles

S. Ueno[1], T. Okimura[1], K. Kato[2]

[1]Kato Ladies Clinic, IVF Laboratrory, Tokyo, Japan
[2]Kato Ladies Clinic, Gynecology, Tokyo, Japan

Study question: Does increasing the size of a training dataset improve the performance of pregnancy (fetal heartbeat) prediction in a deep-learning model?

Summary answer: Yes. Increasing the training data for a deep-learning model for embryo selection improved prediction of the likelihood of implantation after single vitrified-warmed blastocyst transfer (SVBT).

What is known already: Recently, artificial intelligence (AI) for implantation prediction after blastocyst transfer has been extensively studied. AI can address the issue of subjective assessment for the selection of blastocyst transfer. Generally, the performance of deep learning models is said to improve by increasing the training dataset. However, to the best of our knowledge, there exists no study on the effect of increasing training data on the performance of pregnancy prediction on the same deep-learning model.

Study design, size, duration: A total of 3,960 SVBT cycles (1 patient,1 cycle) were retrospectively analyzed. Embryos were stratified according to SART age groups. The quality and scoring of embryos were assessed by iDAScore v1.0 (iDAV1; Vitrolife, Sweden), v2.0 (iDAV2; Vitrolife, Sweden), and Gardner grading. The discriminative performance of the pregnancy prediction for each embryo scoring model was compared using the area under the curve (AUC) of the receiver operating characteristic curve for each maternal age group.

Participants/materials, setting, methods: Embryos were cultured in the EmbryoScope+ and/or EmbryoScope Flex (Vitrolife). iDAV2 and iDAV1 were based on an identical deep-learning architecture, but the training data for iDAV2 has been increased with 15% more data. ICM and TE were annotated according to the Gardner grading system. The degree of blastocyst expansion was Grade 4 due to our freezing policy. Furthermore, Gardner's grading (GG) was stratified into four grades (A: AA, B: AB BA, C: BB, D: others).

Main results and the role of chance: The AUCs of the < 35 years age group (n = 757) for pregnancy prediction were 0.718 for iDAV1, 0.733 for iDAV2, and 0.694 for GG. The AUC of iDAV2 was significantly higher compared to GG ($P < 0.05$).

For the 35–37 years age group (n = 821) the AUCs were 0.696, 0.712, and 0.695 for iDAV1, iDAV2, and GS, respectively, and were significantly different between iDAV1 and iDAV2 ($P < 0.05$). The AUCs of the 38–40 years age group (n = 1,007) were 0.698 for iDASV1, 0.706 for iDAV2, and 0.700 for GG and there was no significant difference. The AUCs of the 41–42 years age group (n = 715) were 0.734, 0.745, and 0.696 for iDAV1, iDAV2, and GS, respectively, and the AUC of iDAV2 was not significantly different compared to iDAV1 ($P = 0.174$) but significantly different compared to GG ($P < 0.05$). For the > 42 years age group (n = 660) AUCs were 0.685 for iDAV1, 0.698 for iDAV2, and 0.682 for GS and were not significantly different among groups. The AUCs of iDAV1, iDAV2, and GG in all ages were 0.736, 0.720, and 0.702, respectively. iDAV2 were significantly higher than iDAV1 and GG ($p < 0.05$).

Limitations, reasons for caution: This study was based on minimal stimulation and natural cycle IVF treatment, and a freeze-all strategy whereby all transferred blastocysts had previously been vitrified. Therefore, we had only a few cycles with elective blastocyst transfer. In addition, this study was retrospective in nature.

Wider implications of the findings: For all age groups, iDAV2 had a higher AUC than iDAV1, although a significant difference was only observed for the young age group. This result suggests that the increased dataset used for the development of iDAV2 improved the performance of pregnancy prediction for SVBT in the deep-learning model.

P-114 Abdominal obesity in Polycystic ovary syndrome patients can increase endometrial stromal cells decidualization

Z. Shalchian[1], S. Taheri[1], M. Hafezi[2], F. Shirvanizadeh[3], N. Nasiri[4], P. Eftekhari yazdi[4]

[1]Faculty of Development of Biology- University of Science and Culture- Tehran- Iran, Reproductive Medicine, Tehran, Iran
[2]Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran., Obstetrics and Gynaecology, Tehran, Iran
[3]Department of Biology- Science and research Branch- Islamic Azad University- Tehran- Iran, Reproductive Medicine, Tehran, Iran
[4]Department of Embryology- Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran., Reproductive Medicine, Tehran, Iran

Study question: Whether abdominal obesity can change the decidualization induction potential in PCOS patients?

Summary answer: We hypothesized that considering the inflammatory origin of abdominal obesity, it may affect decidualization potential of endometrial stromal cells (ESCs).

What is known already: Polycystic ovary syndrome (PCOS) as a chronic inflammatory disease is the most common hormonal disorder in women of reproductive age, which is often associated with subfertility or infertility due to ovulation disorders and subsequently low pregnancy rate, live birth rate and a high miscarriage rate. Inflammatory Abdominal obesity (AO) is the most common phenotype in PCOS patients, which has a high association with PCOS pathogenesis. Embryo-endometrium cross-talk has a key role in successful embryo implantation, which contains inflammatory phase (decidualization induction). Followed by inflammatory phase for pregnancy support.

Study design, size, duration: Our study population were consisting of 53 infertile women including PCOS diagnosed according to Rotterdam criteria (n = 25) and normal oogenesis women (male factor infertility) (n = 28) with in vitro fertilization (IVF) / intracytoplasmic sperm injection (ICSI) and frozen embryo transfer (FET) indication. All patients were aged 25-35 referred to Royan Institute between 1st May until 1st December in 2021 for infertility treatments.

Participants/materials, setting, methods: The embryos were subdivided into four groups: PCOS with AO, PCOS without AO, nonPCOS with AO, and nonPCOS without AO patients. The embryos from each group were single cultured up to the blastocyst stage. Their embryo condition media (ECM) were pooled and added to the culture media of healthy ESCs monolayer to investigate their effects on decidualization potential via gene and protein expression analysis and ESCs migration assay.

Main results and the role of chance: Results showed that ECM generally can improved decidualization capacity in ESCs. Morphological analysis, migration assay, protein and gene expressional analysis showed PCOS with AO had the highest decidualization potential and revealed by higher expression of decidualization markers ($P \leq 0.05$). NonPCOS individuals without AO had the lowest level of both gene and protein decidualization markers ($P \leq 0.05$).

Limitations, reasons for caution: Due to small sample population and the ECM volume limitation, the present study remained focused on the some main decidualization markers rather than extended study.

Wider implications of the findings: Inflammation may increase endometrial receptivity, allowing more suboptimal embryos to implant; this could explain the high rate of abortion in these cases. Controlling the inflammation in PCOS patients with AO may correct the decidualization profile of these patients.

P-115 Clinical prognosis of abnormally cleaved embryos: time-lapse evidence of self-correction before blastulation

Y. Liu[1], K. Bickendorf[1], K. Peirce[1], J. Natalwala[1], V. Chapple[1]

[1]Fertility North, Laboratory, Joondalup, Australia

Study question: What is the clinical prognosis of embryos displaying abnormal cleavage (ABNCL) observed via time-lapse videography (TLV) and the role of blastulation in embryo self-correction?

Summary answer: ABNCL leads to reduced blastulation rate, but not live birth rates and neonatal outcomes once blastulation has been achieved.

What is known already: It is widely accepted that ABNCL is associated with reduced viability in cleavage stage human embryos. However, evidence is scarce in literature reporting birth outcomes from blastocysts arising from such embryos, mostly because they are ranked low priority for transfer. Knowledge is also limited regarding the potential self-correction mechanism in those leading to live births. In this study, using a large dataset of blastocysts with known live birth outcomes, we aimed to explore the role of blastulation in the self-correction process of ABNCL embryos, and their subsequent live birth rates as well as neonatal outcomes following intrauterine transfer.

Study design, size, duration: This retrospective study involved 1562 consecutive autologous *in vitro* fertilization cycles (maternal age 35.1 ± 4.7 years) performed at Fertility North between January 2017 and June 2022. Fresh transfers were routinely performed on Day 3 with remaining embryos cultured up to Day 6. A total of 9451 embryos were subject to blastocyst culture, with a subset of 664 resulting blastocysts (following single frozen transfers up to August 2021) included for live birth and neonatal outcome analysis.

Participants/materials, setting, methods: A total of 6019 out of 9451 embryos were annotated for ABNCL up to Day 3, including direct cleavage (DC), reverse cleavage (RC) and <4 intercellular contact points at 4-cell stage (<4ICCP). The remaining 3432 embryos were excluded from TLV annotation due to poor quality as per the 2011 Istanbul consensus. For DC and RC, the number of affected blastomeres was also recorded for the 1st (1-cell), 2nd (2-3-cell), and 3rd cleavage cycles (4-8-cell), respectively.

Main results and the role of chance: Embryos showing DC (19.5%), RC (41.7%), <6ICCP (58.8%), and Mixed (affected by 2 or 3 ABNCL types, 26.4%) had lower blastulation rates than those without ABNCL (67.2%, $P < 0.01$ respectively). Subgroup analysis showed increasing blastulation rates along cleavage cycles of DC/RC occurrence, from 1st through 2nd to 3rd cleavage cycles (DC 6.3%, 20.7% and 41.0%, $P < 0.001$; and RC 10.0%, 32.3% and 45.8%, $P < 0.05$). Negative correlation ($P < 0.05$ respectively) was also identified between the number of blastomeres affected by DC/RC and subsequent blastulation. However, once blastulation was achieved, clinical results were comparable between blastocysts with DC, RC, <6ICCP and No ABNCL; including live birth rates (25.9%, 33.0%, 36.0% vs 30.8%, $P > 0.05$ respectively), gestational age (38.7 ± 1.6, 38.5 ± 1.2, 38.3 ± 3.5 vs 38.5 ± 1.8 weeks, $P > 0.05$ respectively) and birthweight (3343.0 ± 649.1, 3378.2 ± 538.4, 3352.6 ± 841.3 vs 3313.9 ± 509.6 grams, respectively). Above findings held true following multivariate regression (logistic or linear as appropriate); adjusting for maternal age and BMI, vitrification day, blastocyst expansion stage, ICM/TE grades, insemination methods and sperm types. Also, no difference was detected using either Z-score as endpoint combining birthweight, baby sex and gestational age; or preterm delivery (<37 weeks) or low birthweight (<2500 grams) incidences as endpoints. Live-birth embryo TLV indicated self-correction mechanisms by excluding/extruding DC/RC cells before blastulation.

Limitations, reasons for caution: Our study is limited by its retrospective nature, making it impossible to control all known/unknown confounders. Embryos in our dataset, being surplus after selection for those with no or minimum ABNCL for fresh transfer on Day 3, may not represent the full embryo cohort.

Wider implications of the findings: Our findings further support the embryo self-correction mechanism where DC/RC affected blastomere is excluding/extruded at blastulation, which is evidenced by TLV of live-birth embryos. The assuring live birth rates and neonatal outcomes in ABNCL blastocysts provide valuable guidance to clinical practice and patient counselling.

P-116 How does the short insemination method affect clinical outcomes and laboratory management?

Y. Matsuda[1], S. Watanabe[1], M. Tomida[1], S. Suzuki[1], K. Yoshikai[1], E. Nakano[1], T. Sawada[1]

[1]Sawada Women's Clinic, ART Lab., Nagoya, Japan

Study question: Does the short insemination method using a time-lapse monitoring system improve clinical outcomes and laboratory management?

Summary answer: The method increased the normal fertilization rate of Conventional IVF and also increased the 3PN rate. The working environment of the laboratory staff was improved.

What is known already: Short insemination using a time-lapse monitoring system has been reported to reduce fertilization confirmation failures due to loss of pronuclei, but many reports indicate that the method was implemented to perform so-called 'rescue ICSI' for unfertilized oocytes on the day of egg retrieval and there are not many reports of clinical outcomes in conventional IVF without rescue ICSI. There are also few reports on the working environment and working hours in the laboratory.

Study design, size, duration: This was a retrospective study of 3,714 oocytes from 715 cycles in 595 patients who underwent Conventional IVF with egg retrieval in 2016-2022.

Long insemination (1,577 oocytes) was performed in cycles up to May 2019 and short insemination (2,137 oocytes) in later cycles.

In IVF, 40,000 motile sperm were placed in 1 ml of culture medium per oocyte.

Participants/materials, setting, methods: Oocytes of the long insemination group (group L) were inseminated 5 hours after egg retrieval and denuded 19 hours later to observe their pronuclei.

Oocytes from the short insemination group (group S) were inseminated 2 hours after egg retrieval, denuded 4 hours later, and cultured in EmbryoScope (Vitrolife, Sweden) to observe the pronuclei.

Since the working hours set at our clinic are 8:00 a.m.-5:00 p.m., the time schedule for both groups followed this schedule.

Main results and the role of chance: The 2PN rate was 60.9% in group L and 64.7% in group S. The 3PN rates were 7.5% and 10.2% respectively, both rates being significantly higher in group S ($P < 0.05$). The non-fertilization rates were significantly higher in group L (25.3% and 21.7% respectively); the 1PN rate was not significantly different (3.6% vs. 3.4%).

The rate of missed pronuclei was 2.8% in group L and 0% in group S.

Early embryo transfer pregnancy rate (25.4% vs 27.8%), good blastocyst development rate (52.2% vs 63.6%) and blastocyst transfer pregnancy rate (41.1% vs 31.7%) in groups L and S respectively.

The good blastocyst incidence was significantly higher in group S.

In the case of the Conventional IVF cycle in which egg retrieval was performed at 8:00 a.m., the embryologists in group L were to observe the pronuclei at 8:00 a.m. the next day, but in reality the embryologists had to come to work earlier because of denudation, and even then pronuclear loss occurred.

In contrast, the group S did not require an earlier attendance because denudation was not performed the next morning, and the time-lapse images did not fail to confirm the pronuclei at all.

Limitations, reasons for caution: Since the short insemination method was introduced at our clinic in June 2019, this study compared clinical outcomes before and after that date.

Wider implications of the findings: It has been reported in the past that early insemination time increases both 2PN and 3PN rates. The short insemination method in this study also used a faster insemination time, which may have led to similar insemination results.

P-117 The reason why direct cleavage and rapid cleavage should be differentiated

S. Watanabe[1], M. Tomida[1], S. Suzuki[1], Y. Matsuda[1], K. Yoshikai[1], E. Nakano[1], T. Sawada[1]

[1]*Sawada Women's Clinic, ART Lab., Nagoya, Japan*

Study question: Direct cleavage (DC) and Rapid cleavage (RaC) both appear to be 1 cell divided into 3 (or more) cells, should they be distinguished?

Summary answer: Since blastomeres by RaC had higher developmental potential than blastomeres by DC, and since many RaC embryos had "normal" blastomere, the two should be distinguished.

What is known already: DC, in which one cell divides into three (or more) cells without the two-cell stage, and RaC, in which one or two cells divide rapidly after the short two-cell stage (The former lead to segregation of chromosomes into three cells, while the latter leads to inadequate DNA replication), are both often recorded as "DC", but when classified in detail, there are reports that the blastocyst development rate is higher in RaC embryos. However, the reason for this has not been clarified.

Study design, size, duration: This was a retrospective study of 643 embryos collected and cultured for at least 5 days in 2020 at our clinic. The embryos were time-lapse monitored by EmbryoScope (Vitrolife, Sweden) and classified into three groups according to the style of first division.

Participants/materials, setting, methods: The embryos were classified as follows: DC group: embryos that have divided into three (or more) cells without a two-cell stage; RaC group: embryos that rapidly (<5 hours) divided one (or both) cells after the 2-cell stage; Normal cleavage (NC) group: embryos that had a 2-cell stage for more than 5 hours. The subsequent development of blastomeres of all embryos was observed and whether they participated in blastocysts or not was recorded.

Main results and the role of chance: Of the embryos, 63 were in the DC group and 199 were in the RaC group (173 of which had one rapidly dividing blastomere and 26 of which had two). The blastocyst participation rate of blastomeres was 4.4% in the DC group, 19.5% of rapidly dividing blastomeres and 61.6% of normal blastomeres in the RaC group, with significant differences between all groups ($p < 0.01$). The good blastocyst (4BC or higher in Gardner grade) development rate was 4.8% (3/63) in the DC group, 40.5% (70/173) in the RaC group with one rapidly dividing blastomere (RaC1 group), 19.2% (5/26) in the RaC group with two such blastomeres (RaC2 group), showing a significant difference between the DC and RaC1 groups ($P < 0.01$). The live birth rate for single blastocyst transfer was 50% (1/2) in the DC group, 27.8% (5/18) in the RaC1 group, and 100% (1/1) in the RaC2 group. (Note that there were 381 in the NC group, and the above rates were 76.5%, 63.3% (241/381), and 29.3% (22/75), respectively)

Limitations, reasons for caution: This study examined only the style of first division and did not consider second and subsequent divisions. In addition, as of 2020, the clinical use of PGT-A is not approved in principle in Japan, and the subject embryos have not undergone chromosome analysis.

Wider implications of the findings: The reason for the higher blastocyst development rate in RaC embryos was indicated by the difference in blastocyst participation rates of the respective blastomeres and the presence of normal blastomeres, but since live births were obtained in both embryos, so these irregular divisions would not completely compromise the blastocyst euploidy.

Trial registration number: not applicable

Abstract citation ID: dead093.482

P-118 Are cumulus cells required during in vitro maturation of human oocytes at the germinal vesicle stage? a systematic review

T. Yurchuk[1], V. Piniaiev[2], M. Petrushko[3]

[1]*Institute for Problems of Cryobiology and Cryomedicine of the NAS of Ukraine, Cryobiology of Reproductive System, Kharkiv, Ukraine*
[2]*ART- clinic of reproductive medicine, Reproductology, Kharkiv, Ukraine*
[3]*ART-clinic of reproductive medicine, Embryology, Kharkiv, Ukraine*

Study question: Does the presence of cumulus cells affect the *in vitro* maturation (IVM) rate of human oocytes at the germinal vesicle (GV) stage obtained in vivo?

Summary answer: The oocyte maturation and fertilization rates are higher in the presence of cumulus cells (CC) comparing with their absence in the culture system.

What is known already: According to the ESHRE guidelines IVM is currently not considered experimental, but nevertheless it is not very often used in reproductive medicine clinics. Accumulated data of more than 30 years of existence of IVM method can present to us how effective is the level of oocytes maturation *in vitro* obtained by aspiration follicles *in vivo*. Some studies reported that oocytes were matured after denudation, and in others they are cultured in cumulus oocyte complexes or in the presence of CC. Therefore, a comparison of oocyte maturation at the GV stage with and without CC was performed in this study.

Study design, size, duration: We searched Medline and Embase up to January 10, 2023. Full texts of classical articles, clinical studies, clinical trials, clinical trial protocols, comparative studies, controlled clinical trials, multicentre studies, randomized controlled trials were included

Participants/materials, setting, methods: Participants were women undergoing infertility treatment with IVM. All oocytes from the included studies were obtained by follicular aspiration *in vivo*.

Main results and the role of chance: A preliminary screening of the word combination "human oocyte in vitro maturation" yielded 355 results, from which 42 were original publications with full-text. Selected papers included a full description of the stimulation protocol, maturation medium, and the group of immature oocytes consisted of gametes only at the GV stage. A total of 24,649 GV oocytes were examined for IVM rate. The average of oocyte maturity was 61.5 ± 10.7%. However, the distribution of oocyte maturation data depending on the presence or absents of CC in the culture media. The maturation rate was higher in oocytes with cumulus cells than in denuded oocytes without cumulus (64.7% *vs* 53.5%, respectively, $p<0.05$). The fertilization rate had the same tendency (69.2% vs. 59.5%, $p<0.05$). However, there was no significant difference between the groups in embryo development up to the cleavage stage (74.9% vs 76.5%, $p > 0.05$). Unfortunately, there are very only a few studies that provide data on the more advanced stages of embryo development as a blastocyst, which does not allow a large sample to be made for any IVM method.

Limitations, reasons for caution: This study does not take into account the influence of stimulation protocols and the composition of the maturation medium, which may in turn also affect the results of oocyte IVM.

Wider implications of the findings: The obtained data can be used for comparison with new maturation protocols that will be aimed at increasing the maturation rates, in addition, these data are important for comparing the efficacy of maturation obtained from ovaries outside the body for the purpose of preserving fertility.

Trial registration number: not applicable

Abstract citation ID: dead093.483

P-119 Relation of graphical follicle models to the cumulative live birth rate in GnRH-antagonist stimulation treatment cycles

J. Yang[1], X. Zhang[1], G. Huang[1]

[1]*chongqing health center for women and children, Chongqing Key Laboratory of Human embryo Engineering, chongqing, China*

Study question: Is it possible to create a model that combines follicle number and size to help physicians visualize the trigger requirements to predict oocyte utilization?

Summary answer: Findings support graphical follicle model as an innovative, simple, and practiced parameter for predicting clinical results in ovary stimulation treatment and facilitating personalized protocol adjustment.

What is known already: Previous studies have observed the number and size of follicles are two independent indicators of whether the oocyte is

adequate and mature and are used to predict the trigger time in routine clinical practice. However, due to individualized differences, it currently relies mainly on physician experience.

Study design, size, duration: This retrospective study included 8405 patients started their first in vitro fertilization cycle with a GnRH-ant protocol including fresh and subsequent frozen-thawed cycles during 2016–2020.

Participants/materials, setting, methods: We classified follicles recorded on the HCG day by size. We then produced graphical models, and classified into Inverted-trapezoid (large follicles in dominant proportion), Polygon (moderate follicles in dominant proportion), Trapezoid (small follicles in dominant proportion), Rectangle (equivalent proportions of the three size categories). The Cochran–Mantel–Haenszel and Generalized Linear Model(GLM) were used to evaluate the difference among models in relation to maturity, fertilization, and number of viable embryos, as well as cumulative live birth rate.

Main results and the role of chance: In GLM analysis, after adjusting the confounders, there are differences between models of CLBR. The CLBR of the different models was higher in the Polygon and Inverted-trapezoid model than Trapezoid and Rectangle model (42.75%, 39.56%, vs. 37.38%, 28.57%, respectively; all $P<0.05$). For oocytes derived from very large follicles (>20 mm), the CLBR was lower than that of patients with ≤ 20 mm follicles [26.10% vs. 42.10%, OR = 1.74 (95% confidence interval 1.52–2.00), $P<0.01$] in Inverted-trapezoid model, but there was no difference between models.

And the risk of ovarian hyperstimulation syndrome (OHSS) rate of patients with ≤ 20 mm follicles was lower than that of patients with >20 mm follicles [8.64% vs. 17.89%, OR = 0.57 (95%CI: 0.49−0.65), $P<0.01$] in Inverted-trapezoid model. Patients who received an adjusted Gn dose(whether Decreased or Increased-dose protocol) showed no difference in CLBR among models (Polygon vs Inverted-trapezoid vs Trapezoid vs Rectangle model: 47.07% vs. 49.21% vs. 47.69% vs. 42.42%, $P>0.05$); but when patients continued with the same starting dose in Fixed-dose protocol, the CLBR of the Polygon model was higher than that of other models (40.43% vs. 34.32, 31.13% vs. 26.46%, respectively; all P value <0.05).

Limitations, reasons for caution: This study is retrospective. Due to analysis of real-world data, the follicular corresponding outcome following measurement was not obtained. Besides, the majority of patients received 2 cleavage stage embryos transfer, this approach may impact the external validity of follicle model.

Wider implications of the findings: The follicle models can demonstrate ovarian response of patients. It is better for patients to reach the Inverted-trapezoid model with dominate follicles >18 mm and <20 mm. Adjusting the protocol is critical to the outcome. But how to improve follicle models by regulating stimulation remains to be further studied.

Trial registration number: not applicable

P-120 Seasonal effects at the time of oocyte collection on the success of frozen embryo transfers

S. Leathersich[1], R. Hart[2], C. Roche[1], M. Walls[3]

[1]*King Edward Memorial Hospital for Women, Reproductive Medicine, Subiaco, Australia*
[2]*University of Western Australia, Reproductive Medicine, Subiaco, Australia*
[3]*Fertility Specialists of WA, Scientific Director, Claremont, Australia*

Study question: Does season and duration of daylight hours at the time of oocyte collection impact on live birth rates following frozen embryo transfer?

Summary answer: Frozen embryo transfer following oocyte collection in summer had 30% increased odds of live birth compared to oocytes collected in autumn.

What is known already: Season and conditions at the time of fresh or frozen embryo transfer do not appear to impact live birth rates. Recent data from the northwest USA suggest increased live birth rates following frozen embryo transfer from oocytes collected in summer, independent of the season at the time of transfer.

Study design, size, duration: Retrospective cohort study of all frozen embryo transfers at a single centre in Western Australia from 2013 - 2021 for which oocyte collection also occurred between these dates. This study included 3,659 frozen embryo transfers with embryos generated from 2,155 IVF cycles in 1,835 patients. Data were analysed by season, temperature and recorded sunshine hours at the time of oocyte collection and embryo transfer.

Participants/materials, setting, methods: All transfers during the study period were included; demographics, IVF cycle characteristics, embryological data and clinical outcomes were collected from the clinic database. Weather data were recorded by the Australian Bureau of Meteorology. Statistical adjustment was performed for factors known to affect live birth rates, and we corrected for multiple cycles in the same patient and conditions at embryo transfer.

Main results and the role of chance: Compared to frozen embryo transfer (FET) with oocyte retrieval dates in autumn, FET with oocyte retrieval dates in summer had 30% increased odds of live birth (OR: 1.30, 95% CI: 1.04-1.62). Temperature at the time of oocyte retrieval did not affect LBR; there was a 28% increase in odds of live birth when the sunshine hours were in the highest tertile compared to the lowest on the day of oocyte retrieval (OR: 1.28, 95% CI: 1.06-1.53). These findings remained consistent when adjusted for season or sunshine hours on the day of FET respectively.

Odds of livebirth were decreased by 18% when the minimum temperature on the day of transfer was high compared with low (OR: 0.82, 95% CI: 0.69−0.99).

The duration of bright sunshine on the day of oocyte retrieval appeared to drive the seasonal variations, whereas ambient temperature was not associated with clinical outcomes.

Limitations, reasons for caution: This was a retrospective study, however study populations across seasons, temperature tertiles and sunshine tertiles were similar. We did not analyse subgroups of low prognosis patients. We also did not analyse environmental pollutants in this study, nor did we assess impacts on sperm quality. These may all affect the results.

Wider implications of the findings: Optimal conditions for livebirth appear to be associated with summer and increased sunshine hours on the day of oocyte retrieval. Consideration could be given to timing oocyte retrieval to optimise outcomes. The mechanisms remain to be clarified, though may involve melatonin and its impact on oocyte quality.

P-121 Identification of differentially expressed genes common to the developmental potential, maternal age, and morphology in human blastocysts

Y. Kai[1], H. Mei[2], H. Kawano[1], N. Nakajima[1], A. Takai[1], M. Kumon[2], A. Inoue[2], N. Yamashita[1]

[1]*Yamashita Shonan Yume Clinic, Reproductive Medicine Research Center, Fujisawa, Japan*
[2]*RIKEN, Center for Integrative Medical Sciences, Yokohama, Japan*

Study question: Is it possible to apply RNA-sequencing to assisted reproductive technology (ART) to predict blastocyst quality?

Summary answer: We identified 14 commonly identified differentially expressed genes by grouping blastocysts according to three distinct parameters such as developmental potential, maternal age, and Gardner score

What is known already: In ART, while the selection of a suitable embryo for transfer is critical for a successful pregnancy, neither preimplantation genetic testing nor morphological and chronological evaluation of the embryo can fully guarantee a successful pregnancy. Recently, transcriptional events in early human embryonic development have been analyzed using RNA-sequencing (RNA-seq) and researchers are attempting to apply this information to ART. We have reported that 96 differentially expressed genes (DEGs) were identified using RNA-seq of each inner cell mass (ICM) and trophectoderm (TE) in blastocysts classified according to the developmental potential which correlates with pregnancy rate at the ESHRE 37th annual meeting.

Study design, size, duration: After retrospectively analyzing 1,890 cases undergoing freeze-thaw blastocyst transfer from March 2018 to December 2020 to examine the correlation between blastocyst developmental potential and pregnancy rate, a total 13 blastocysts cryopreserved between February 2011 and September 2018, then scheduled for disposal and with consented, were subjected to RNA-seq to identify genes associated with pregnancy expectation. RNA-seq data were then examined whether common DEGs could be found when classified by maternal age and Gardner score, respectively.

Participants/materials, setting, methods: Blastocysts were donated by infertile couples undergoing c-IVF or ICSI cycles at the Yamashita Shonan Yume Clinic with informed consent under ethical approval. TE cells and ICM cells were collected from blastocysts classified by developmental potential and subjected to RNA-seq to identify DEGs. In addition, RNA-seq data were regrouped by maternal age and Gardner score to find common DEGs. DEGs (q-value < 0.01) were identified using the R package "DESeq2" (version 1.32.0).

Main results and the role of chance: When the RNA-seq data obtained from blastocysts classified according to pregnancy expectation were re-grouped by maternal age and re-analyzed, we identified 7 and 17 genes that were down- and up-regulated in the elder group, respectively, in ICM. In TE, 2 and 12 genes were down- and up-regulated in the elder group, respectively. On the other hand, when re-grouped by Gardner score (<BB versus <BB), we identified 26 and 29 genes that were down- and up-regulated in the poor group, respectively, in ICM. In TE, 64 and 20 genes were down- and up-regulated in the poor group, respectively. A comparison of these genes and DEGs identified by the pregnancy expectation found 14 common genes. By comparison with the elder group, we identified one gene (*UCHL1*) that was commonly up-regulated in TE. By comparison with the poor Gardner score group, one gene (*CMTM7*) was commonly down-regulated and three genes (*LINC00458*, *DYNLRB1*, and *UBL4A*) were commonly up-regulated in ICM, and 5 genes (*LRIG3*, *SLC28A3*, *CXADR*, *LOC727896*, and *ATP1B1*) were commonly down-regulated and 5 genes (*UCHL1*, *BZW2*, *NABP1*, *HEXIM1*, and *PLEKHA6*) were commonly up-regulated in TE.

Limitations, reasons for caution: Although we established an expected pregnancy rate concerning the degree of blastocyst development from retrospective clinical outcomes and used it as a surrogate marker for assigning biopsied blastocysts to different analysis groups, it remains unknown whether the gene expression profiles accurately reflect the pregnancy outcomes.

Wider implications of the findings: *UCHL1* expression was commonly increased with lower blastocyst developmental potential, higher maternal age, and lower Gardner score. Since *UCHL1* has been reported to be essential for blastocyst development in mice, our results suggest that *UCHL1* may also be a marker of blastocyst quality in humans.

P-122 Evaluation of an updated artificial intelligence embryo viability model on implantation and miscarriage

A.V. Gabrielsen[1], M.N. Johansen[2], L.H. Iversen[1], M. Montag[3], J. Berntsen[4]

[1]*Fertilitetsklinikken Horsens, Fertilitetsklinikken, Horsens, Denmark*
[2]*Vitrolife A/S, Vitrolife A/S-, Aarhus, Denmark*
[3]*ilabcomm GmbH, ilabcomm GmbH, Sankt Augustin, Germany*
[4]*Vitrolife A/S, Vitrolife A/S, Aarhus, Denmark*

Study question: Is the implantation and miscarriage prediction performance of the iDAScore model v2.0 increased as compared to the original v1.0 model?

Summary answer: The predictive performance is better for iDAScore v2.0 than for v1.0 on both implantation and miscarriage, although the differences did not reach statistical significance.

What is known already: In recent years, several artificial intelligence (AI) models for the prediction of embryo implantation based on image or time-lapse data have been published and validated in various ways. Some of these models are commercial products while others are more of an academic nature. The long-term benefit of AI models in clinical practice relies on their use in clinical routine and that the models are continuously monitored and updated. The iDAScore time-lapse model has been available from Vitrolife since 2021 and several external validations of iDAScore v1.0 have been published. An updated version (iDAScore v2.0) has recently been released.

Study design, size, duration: This was an observational retrospective study with data collected during the years 2019 to 2022 from one Danish clinic from fresh single embryo transfers performed on day 5. Blastocysts were selected for transfer by experienced embryologists based on morphology (Gardner score). Within the study period, we included all 849 embryos for which we had information on hCG test results, implantation (fetal heartbeat (FH) detected by ultrasound) and live birth (LB).

Participants/materials, setting, methods: Embryos were cultured in an EmbryoScope+ incubator (Vitrolife A/S). Time-lapse images were automatically captured throughout the incubation period. We used the original time-lapse images to calculate scores for iDAScore v1.0 and v2.0 retrospectively. For each version, the predictive performance for miscarriage (early pregnancy loss and clinical miscarriage), FH and LB prediction was expressed in terms of area under the ROC curve (AUC). Differences in performance between versions were assessed in paired comparisons of the AUCs.

Main results and the role of chance: The median age of the transfer recipients was 34 years. One third of the blastocysts was derived from ICSI and the remaining from standard IVF cycles. Among all transferred blastocysts, the hCG rate was 58.0% (492/849), the FH rate was 46.5% (395/849), the LB rate was 42.4% (360/849), and the overall miscarriage rate from hCG to live birth was 26.8% (132/492).The overall AUC for FH prediction was 0.652 (0.616 to 0.689) for iDAScore v2.0 compared to 0.632 (0.595 to 0.669) for v1.0. Similarly, the AUC for LB prediction was 0.644 (95% CI: 0.607 to 0.681) for iDAScore v2.0 compared to 0.626 (95% CI: 0.588 to 0.663) for iDAScore v1.0. However, these differences were not statistically significant (P-values: 0.12 for FH and 0.17 for LB) in paired comparisons.For miscarriage, we found an increase in AUC from v1.0 (0.574; 95% CI: 0.514 to 0.633) to v2.0 (0.592; 95% CI: 0.534 to 0.649), P-value: 0.40.

Limitations, reasons for caution: This study only includes data from a single clinic. Patient characteristics and procedures followed might not be representative for other clinics. The data is limited to blastocysts that were chosen for transfer by morphology from trained embryologists. Furthermore, the limited sample size does not provide statistically significant differences in performance.

Wider implications of the findings: It is important that predictive models are constantly updated and improved. Updated versions should take into account a larger database as well as potential new methodologies that evolve in the rapidly developing AI field. This study shows that the iDAScore model update seems to represent an actual performance increase.

P-123 Early irregular division of human embryos changes in style between the first and second divisions

M. Tomida[1], S. Watanabe[1], S. Suzuki[1], Y. Matsuda[1], K. Yoshikai[1], E. Nakano[1], T. Sawada[1]

[1]*Sawada Women's Clinic, ART Lab., Nagoya, Japan*

Study question: Is there a difference in irregular division kinetics between first and second division of human embryos?

Summary answer: The incidence of rapid cleavage was reduced in the second division, but the developmental potential of the blastomeres by this dynamics was unexpectedly low.

What is known already: The styles of irregular division of early human embryos are known: direct cleavage (DC), in which one cell becomes three (or more) cells without a two-cell phase, and rapid cleavage (RaC), in which one (or both) cells dividing rapidly after two-cell phase, both of which reduces the embryonic developmental potential. However, there are no reports that have examined in detail whether these division styles occur similarly in the first and second divisions, and how these dynamics affect the potential.

Study design, size, duration: This is a retrospective study of 635 embryos collected in 2020 at our clinic and cultured for at least 5 days. The embryos were time-lapse monitored by EmbryoScope (Vitrolife, Sweden) to observe the first and second divisions, and the blastomeres of each embryo were classified according to their style of division.

Participants/materials, setting, methods: It was observed whether there was a DC (division into 3 cells without a 2-cell phase) or RaC (One or two blastomeres divide within 5 hours after the 2-cell phase) at the first division. First dividing normal embryos were observed for the presence of a DC or RaC at the second division. Blastomeres by DC or RaC were observed for subsequent development and whether they participated in blastocysts or not was recorded.

Main results and the role of chance: Among the subject embryos, 63 embryos had DC and 199 embryos had RaC in the first division, and their blastomeres were classified into the DC1 and RaC1 groups, respectively. Of the 373 first division normal embryos, 39 had DC and 23 had RaC (there were 4 embryos with both DC and RaC) in the second division, and their blastomeres were classified into DC2 and RaC2 groups. The blastomeres blastocyst participation rate was 4.4% in the DC1 group and 19.5% in the RaC1 group, respectively, the former was significantly lower ($P < 0.01$), however, in the DC2 and RaC2 groups, 23.3% and 4.2%, respectively, the latter was significantly lower ($P < 0.01$). The incidence of DC was similar in the first (9.9%) and second (10.5%) divisions, but the incidence of RaC was 31.3% in the first division and 6.2% in the second division, the latter was significantly lower ($P < 0.01$). The development rate of good blastocysts (≥4BC in Gardner grade) was 4.8% in embryos with DC1 and 19.5% in embryos with RaC1, with the former significantly lower ($P < 0.01$), 37.0% in embryos with DC2, and 26.3% in embryos with RaC2, with no significant difference.

Limitations, reasons for caution: As of 2020, the clinical use of PGT-A is not approved in principle in Japan, and the subject embryos have not been chromosomally analyzed.

Wider implications of the findings: RaC would lead to inadequate DNA proliferation, but the incidence of this and the prognosis of the blastomeres were different in the first and second divisions. In human embryos, the mechanisms that control blastomeres from dividing may change as development progresses, but further studies are needed to elucidate this.

P-124 Behavior of the second polar body and its relationship to subsequent human embryonic development

T. Shimura[1], K. Yumoto[1], Y. Mio[1]

[1]*Mio Fertility Clinic, Reproductive Centre, Yonago, Japan*

Study question: Is the behavior of the second polar body (PBII) associated with subsequent human embryonic development?

Summary answer: Human zygotes with morphologically static PBII showed significantly higher rates of good quality embryos and utilization than zygotes with PBII showing various behaviors.

What is known already: In recent years, the time-lapse incubators have become widely available, enabling continuous observation of human embryos. With the time-lapse imaging, zygotes with second polar bodies that exhibit a variety of behaviors can be observed from the time of PBII extrusion to the first cleavage. Although the ploidy and morphology of the first polar body have been variously reported to reflect the quality of embryos after fertilization, there are few studies on the second polar body, which is thought to directly reflect the state of oocyte after sperm entry, and its relationship to the embryonic development.

Study design, size, duration: This is a retrospective study involving the time-lapse imaging of 285 normally fertilized ICSI zygotes between January and August 2019. Of those, 262 showing suitable images of PBII from the extrusion to the first cleavage were examined. Zygotes with morphologically static PBII during the observation were classified into Group 1 (n = 68), and zygotes with moving-like-amoeba, shrinking, fragmenting, and/or ruffling PBII were classified into Group 2 (n = 194).

Participants/materials, setting, methods: This study included 64 cycles of ART treatment. Gonadotrophin-releasing hormone analogues (GnRHa) and gonadotrophins were used for ovarian stimulation prior to the oocyte retrieval. Time-lapse imaging was performed in EmbryoScope®. The rates of irregular divisions at the first cleavage, good quality embryos at the early cleavage stage based on the modified Veeck's criteria, good quality blastocysts (≥4BB) based on the Gardner grading system and utilization for cryopreservation and embryo transfer were compared between groups.

Main results and the role of chance: The proportion of Group 1 (morphologically static PBII) and Group 2 (PBII with various behaviors) was 26.0% (n = 68/262) and 74.0% (n = 194/262). The mean maternal age (years) was 34.8 ± 5.4 in Group 1 and 35.0 ± 4.8 in Group 2. The incidence of irregular (direct/reverse) divisions at the first cleavage was 22.1% in Group 1 and 28.9% in Group 2. Good quality embryos at the early cleavage stage were cryopreserved/transferred on Day-2/3 according to our clinic policy, and only those that were not cryopreserved or freshly transferred on Day-2/3 were extendedly cultured up to Day-7. Of those, the rate of good quality blastocysts was 30.6% (n = 11/36) in Group 1 and 23.3% (n = 30/129) in Group 2. Thus, there were no significant differences between Group 1 and 2 in the mean maternal age and the rates of irregular divisions and good quality blastocysts. Meanwhile, the rate of good quality embryos at the early cleavage stage was significantly higher in Group 1 than in Group 2 [$P<0.01$; 57.4% (n = 39/68) in Group 1, 37.1% (n = 72/194) in Group 2]. The utilization rate for cryopreservation and embryo transfer was also significantly higher in Group 1 than in Group 2 [$P<0.05$; 64.7% (n = 44/68) in Group 1, 49.5% (n = 96/194) in Group 2].

Limitations, reasons for caution: This is an observational study using only ICSI zygotes. Since good quality embryos were cryopreserved or freshly transferred on Day-2/3 according to our clinic policy, the number of embryos cultured up to the blastocyst stage was limited to those which were fair or poor quality at the early cleavage stage.

Wider implications of the findings: This study revealed that the rates of good quality embryos and the utilization for cryopreservation or embryo transfer were significantly higher in zygotes with morphologically static PBII than in those with PBII showing various behaviors. This suggests that the behavior of PBII may be a new indicator for embryo evaluation.

P-125 Day 5 endometrium, Is the pregnancy rate following day 5 or day 6 vitrified/thawed blastocysts transfer affected?

E. Gomez-Sanchez[1], D. Castelló[2], R. Diaz[3], N. Almunia[1], M. Valcárcel[1], R. Jiménez[4], A.M. Villaquirán[4], C. Diez[5], L. Quintero[6], J.A. Castilla[7]

[1]*Next Fertility Murcia, IVF Lab, Murcia, Spain*
[2]*Next Fertility Valencia, IVF lab, Valencia, Spain*
[3]*Next Fertility Sevilla, IVF lab, Sevilla, Spain*
[4]*Next Fertility Murcia, Gynecology, Murcia, Spain*
[5]*Gametia, IVF lab, Valencia, Spain*
[6]*Next Fertility Valencia, Gynecology, Valencia, Spain*
[7]*Ceifer Biobanco, Andrology, Granada, Spain*

Study question: Are ongoing pregnancy rates of embryos vitrified on day 5 and day 6 when transferred into a day 5 endometrium comparable?

Summary answer: Day 5 blastocysts implant better in day 5.5 endometrium than day 6, whether they were vitrified on day 6 or 5 and cultured 24 hours.

What is known already: Preparation of the endometrium for transfer of cryopreserved embryos is usually done so that transfer takes place on endometrial day 5, although embryos may be at day 5 or 6 of development, so there may be asynchrony between the endometrium and the embryo if a day 6 embryo is transferred. Fresh transfer of day 5 blastocysts has been reported to have better results than day 6 blastocysts, predictably due to this endometrial asynchrony. However, data from frozen blastocyst transfers are less

clear, possibly due to heterogeneity of the patient population and/or embryo quality.

Study design, size, duration: In this study we aim to analyse whether ongoing pregnancy after vitrified/thawed embryo transfers is affected if day 5 or day 6 embryos are transferred into day 5 endometrium. For this purpose, we examined 2266 cryotransfers performed in three Next Fertility clinics in Spain between 2016 and 2022. Day 5 (n = 1583) and 6 (n = 519) blastocyst transfers and day 5 embryos that devitrified one day before transfer (n = 164) were retrospectively compared.

Participants/materials, setting, methods: In this work blastocyst transfers were performed from donor or autologous oocytes, with or without PGT-A. Embryos were vitrified on day 5 or 6. Endometria were prepared with hormone replacement therapy or in natural cycle. All FET were performed after 5.5 days of progesterone exposure, regardless of embryo stage (day 5 or 6). The results were analysed considering all the above groups.

Main results and the role of chance: Ongoing pregnancy are superior with day 5 blastocysts versus day 6 and day 5 cultured for 24 hours prior to transfer. However, day 6 blastocysts were similar to cultured ones.

Own oocytes: Day 5 44.98% (n = 538) vs Day 6 35.75% (n = 207) ($p < 0.03$); Day 5 44.98% vs Day 5 cultured 32.58% (n = 89) ($p < 0.03$); Day 6 35.75% vs Day 5 cultured 32.58% ($p > 0.05$).

Donated Oocytes: Day 5 45.86% (n = 726) vs Day 6 28.51% (n = 221) ($p < 0.00001$); Day 5 44.98% vs Day 5 cultured 39.34% (n = 61) ($p > 0.05$); Day 6 28.51% vs Day 5 cultured 39.34% ($p > 0.05$).

PGT-A Own oocytes: Day 5 51.72% (n = 203) vs Day 6 25.39% (n = 63) ($p < 0.003$); Day 5 51.72% vs Day 5 cultured 40.00% (n = 10) ($p > 0.05$); Day 6 25.39% vs Day 5 cultured 40.00% ($p > 0.05$).

PGT-A Donated Oocytes: Day 5 42.24% (n = 116) vs Day 6 35.71% (n = 28) ($p > 0,05$); Day 5 42.24% vs Day 5 cultured 40.00% (n = 4) ($p > 0.05$); Day 6 35.71% vs Day 5 cultured 50.00% ($p > 0.05$).

Miscarriage rates were similar across all groups.

Limitations, reasons for caution: Not all cohorts in the study were equally large, so some results have less statistical power, especially in abortion rates.

Wider implications of the findings: Day 5 blastocysts should always be transferred into a 5.5-day endometrium on the day they are devitrified, as this is when they are most synchronous with the endometrium. Further studies are needed to assess whether day 6 embryos implant better in a 6.5-day endometrium than in a 5.5-day endometrium.

Trial registration number: not applicable

P-126 The KAT-Score is a useful indicator for predicting ongoing pregnancy in mosaic risk assessment in PGT-A: a prospective study with single vitrified-warmed blastocyst transfer

Y. Harada[1], E. Fukunaga[1], T. Maeda[1], M. Ikeda[1], R. Shiba[1], S. Okano[1], M. Kinutani[1], S. Tanaka[2], M. Shimada[2], Y. Sakuraba[3]

[1]*Kinutani Women's Clinic, Institute for reproductive medicine, Hiroshima, Japan*
[2]*Varinos Inc., Research & Development, Tokyo, Japan*
[3]*Varinos Inc., Board member, Tokyo, Japan*

Study question: Does the mosaic risk score assessed by the KAT-Score correlate with clinical pregnancy and ongoing pregnancy?

Summary answer: A lower mosaic risk score assessed by the KAT-Score correlated with a higher ongoing pregnancy rate, but not with the clinical pregnancy rate.

What is known already: As the result of preimplantation genetic testing for aneuploidy (PGT-A), the result of analysis for mosaicism is obtained in addition to those for euploidy and aneuploidy. Viotti, *et al.* retrospectively analyzed 1000 mosaic embryo transfers, and showed that the rates of pregnancy and live birth differentiated stepwise depend on the type and level of mosaicism. Although it is possible to determine to the priority of embryo transfer according to the type of mosaicism, no prospective studies have been reported in which embryo transfer was performed using this method of selection.

Study design, size, duration: This is a prospective study conducted in a single IVF center between January 2020 and August 2022. A total of 104 single vitrified-warmed blastocyst transfer cycles were analyzed. The scoring of PGT-A embryos was assessed using the knowledge-based aneuploidy theoretical score (KAT-Score: Varinos Inc., Japan) in the range of 0 to 10. This study was approved by the Ethics Committee of the Institutional Review Board (IRB) of Kinutani Women's Clinic, Hiroshima, Japan.

Participants/materials, setting, methods: The results of 104 vitrified-warmed single blastocyst transfers were classified into pregnancy (54 cycles) and non-pregnancy (50 cycles) groups. They were also classified into ongoing pregnancy (47 cycles) and non-ongoing pregnancy (57 cycles) groups. The correlations between KAT-Score and clinical pregnancy/ongoing pregnancy rates, were analyzed using the Wilcoxon signed-rank test and logistic regression analysis.

Main results and the role of chance: The KAT-Scores for 104 blastocysts ranged from 0 to 9. The distribution of scores is (KAT-Score 0: n = 43; 1-2: n = 21; 3-4: n = 4; 4-5: n = 16; 5-6: n = 7; 6-7: n = 5; 7-8: n = 6; 9: n = 2). First, mean values were compared between two different groups by use of the Wilcoxon signed-rank test. No significant difference in KAT-Score was observed between the pregnancy group and the non-pregnancy group (1.81 ± 2.42 vs. 2.78 ± 2.87; N.S.). On the other hand, the KAT-Score in the ongoing pregnancy group, was significantly lower than that in the non-ongoing pregnancy group (1.34 ± 1.98 vs. 3.04 ± 2.94; $P < 0.01$). Second, binary logistic regression analysis was used to calculate the area under the curve (AUC) as a predictive measure of clinical pregnancy or ongoing pregnancy. The KAT-Score assessment of PGT-A embryos was a predictive indicator of ongoing pregnancy (AUC = 0.67: $P < 0.01$), but not of clinical pregnancy (AUC = 0.59: N.S.). Multivariate logistic regression analysis, which included maternal age and morphological grade as confounding factors, showed that lower KAT-Scores correlated significantly with higher ongoing pregnancy rates (adjusted odds ratio: 0.77, 95% CI: 0.64–0.93, $P < 0.01$). In addition, the ongoing pregnancy rate from embryo transfer with euploid or mosaic embryos was not affected by maternal age or morphological grade.

Limitations, reasons for caution: The main limitation of this study is small sample size. Further research is required to gain a more complete understanding of whether the KAT-Score is associated with pregnancy and ongoing pregnancy.

Wider implications of the findings: This study suggests that the KAT-Score may be used as one of the indicators to predict ongoing pregnancy regardless of maternal age and morphological grade. The scoring of 104 embryo transfers by KAT-Score provides statistically valid evidence for ranking mosaic embryos in the infertility clinic.

P-127 Micro-Magnetic Resonance Spectroscopy of individual mammalian embryos: a safe and non-invasive diagnostic tool for embryo screening in assisted reproduction

G. Conley[1], G. Sivelli[2], K. Marable[2], M. Grisi[2], G. Gruet[2]

[1]*Annaida Technologies, R&D, Lausanne, Italy*
[2]*Annaida Technologies, r&d, Lausanne, Switzerland*

Study question: Is micro-magnetic resonance (micro-MRS) a safe tool to non-invasively unravel the metabolic fingerprint of single mammalian embryos?

Summary answer: We successfully tested the safety of micro-MRS in a mouse model. No long or short-term adverse effect was found in vitro and in vivo.

What is known already: Non-invasive selection of the best embryo to transfer is one of the most significant challenges for ART professionals. The chemical sensitivity, resolving power, and, more importantly, the non-invasive nature of MRS makes it an excellent candidate to investigate the building blocks of complex organisms. Although MRS is a well-established technique for the biochemical profiling of large organisms, handling small samples like embryos and 3D cell cultures and spheroids alongside sensitivity issues has prevented its adoption for clinical and research applications. Our group has

overcome these limitations with microchip-based sensors to leverage non-invasive MRS technology down to the embryo scale.

Study design, size, duration: This safety study was divided into two main phases in order to test all the components needed to operate the micro-MRS analysis. In phase 1 we used >800 2-cell embryos to test a) radiofrequency exposure, b) device activation, and c) static magnetic field exposure. In phase 2 we confirmed in-vivo that MF exposure was not affecting live animals (n267) over 3 generations of mice by assessing different IVF outcomes, natural mating, live parameters and histopathology.

Participants/materials, setting, methods: Cryopreserved 2-cell B6D2F1 mouse embryos were purchased cryopreserved from JanvierLabs. In phase1 embryos were thawed and used for testing micro-MRS main components' safety. Mouse embryo assay (MEA) was used to first assess micro-MRS adverse effects in-vitro. In phase 2 embryos were exposed to magnetic field in a 9.4T Magnet for 1h at 37 °C, then surgically transferred to surrogate mothers. Both mothers and progeny were tracked up to F3. Statistical significance was set at $p < 0.05$.

Main results and the role of chance: This is the first study ever conducted to assess the safety and efficacy of micro-MRS on pre-implantation mammalian embryos. Our results show, with statistical significance, that micro-MRS is safe for use in mammalians. In particular, we have de-risked the three main aspects/components that could affect the embryos: 1) Materials to which the embryos are exposed when loaded into the device, 2) Radiofrequency energy required to activate the device and perform a measurement, and 3) Magnetic field required to analyze the embryos biochemistry in a non-invasive way. Overall no adverse effect was observed when the primary IVF outcomes were assessed, such as implantation rate and live birth rate. In addition, no visible alteration of the overall appearance of ED14.5 foetuses, F1, F2 and F3 mice was observed when comparing the mice obtained from treated or control embryos. The surrogate mothers did not display any significant alteration or visible health issues after embryo transfer. F1 and F2 mice were able to naturally mate and conceive new progeny suggesting that the reproductive potential of the animals is not affected by the magnetic field exposure. Furthermore, histopathological analysis of 5 representative organs did not reveal adverse effects on both surrogate mothers or F1 pups.

Limitations, reasons for caution: A vital step towards establishing MRS as a clinical and research tool is the reliable detection of a wide range of signals from cellular components. Our method is ready for R&D studies, while its clinical application requires further safety studies and protocol optimization.

Wider implications of the findings: A non-invasive quick assay would provide the means to reveal the role of embryonic lipids throughout development. Micro-MRS can further develop into a safe embryo assay for selection before embryo transfer. This would apply to both human and animal ART, whose success rate is relatively low.

P-128 Morphokinetics and blastocyst biomarkers of twin and triplet monozygotic pregnancy using artificial intelligence

J.A. Castilla[1], N. Almunia[2], M. Valcárcel[2], R. Jiménez[3], A.M. Villaquirán[3], A. Brualla[4], A. Zepeda Hernández[5], E. Gómez[2]

[1]*CEIFER Biobanco, Andrology, Granada, Spain*
[2]*Next Fertility Murcia, IVF lab, Murcia, Spain*
[3]*Next Fertility Murcia, Gynecology, Murcia, Spain*
[4]*Fairtility, Embryology, Tel Aviv, Israel*
[5]*Fairtility, Clinical department, Tel Aviv, Israel*

Study question: *Can AI* reduce the rate of twin and triplet monozygotic pregnancies following elective single embryo transfer (eSET)?

Summary answer: AI can automatically annotate morphokinetic developments and other biomarkers. Embryos leading multiple monozygotic pregnancies have slower cell divisions and larger ICM than monoamniotic embryos.

What is known already: Monozygotic twin (MZT) and monozygotic triplet (MTP) pregnancies are a rare phenomenon in spontaneous pregnancies, but the incidence increases significantly when pregnancies are achieved by assisted reproductive technology (ART); 0.4% vs. 1.56% MZTs, and 0.004% vs. 0.048% MTPs. It is unclear what mechanisms cause an embryo to split into two or three, although several have been proposed such as culture to blastocyst, decompacting ICMs, frozen-warmed embryo transfers, assisted hatching and even ICSI. In order to study this split phenomenon, time-lapse imaging has been used to discover any signs of embryo division.

Study design, size, duration: This is a retrospective assessment of a total of 8 embryos from 2018 to 2022 that led to single pregnancy (n = 4), twin pregnancy (n = 3) and triple pregnancy (n = 1) following a fresh single embryo transfer. All embryos were inseminated using the ICSI technique and assisted hatching was performed before fresh transfer.

Participants/materials, setting, methods: Using CHLOE (Fairtility, Tel Aviv) we automatically assessed the morphokinetics, blastocyst biomarkers and scores. Singletons and multiple pregnancies were compared in terms of morphokinetics (t-test) and surface area of ICM, ICM diameter, ICM area/embryo area ratio, ICM shape and CHLOE embryo quality score were compared using the ANOVA test.

Main results and the role of chance: Embryos that led to multiple pregnancies had slower embryo development than embryos that led to singletons (single vs multiple: t2: 22.1+-2 vs 25.2+-2, p = 0.04; t3: 32.56+-2.65 vs 36.98 +-1.48, p = 0.01; t5: 44.09+-4.84 vs 50.37+−0.69, p = 0.02; t6: 47.26+-3.87 vs 53.59+-2.40, p = 0.01; t7: 48.76+-4.04 vs 55.15+-3, p = 0.02; t8: 50.18+-4.27 vs 57.55+-1.5, p = 0.008; t9: 63.27+-3.76 vs 73.04+-5.33, p = 0.03). Embryos leading to triplets were slower than twins which were, in turn, slower than singletons (single vs twins vs triplets: t4: 33.86+-3.41 vs 37.69+-1.61 vs 48.95, p = 0.007; t8: 50.18+-4.27 vs 58.07+-1.29 vs 55.96, p = 0.04; t9: 63.27+-3.76 vs 71.23+-4.81 vs 78.44, p = 0.01).

Embryos that led to multiple pregnancies had a larger ICM to embryo surface area ratio (single vs multiple: 0.14+−0.08 vs 0.27+−0.06, p = 0.04) and smaller embryo diameter (single vs multiple: 177.2+-16.5 vs 138.15+-8.25, p = 0.003).

We didn't find statistically significant differences between the groups in CHLOE EQ score (single vs multiple: 0.97 vs 0.76, p = 0.36), Blast score (single vs multiple: 0.87+−0.06 vs 0.78+−0.13, p = 0.26), CHLOE Rank, Trophectoderm quality, ICM Area (single vs multiple: 3629+-1361 vs 4151 +- 569, p = 0.48) and ICM shape (single vs multiple: 1.64+−0.45 vs 1.27+−0.12, p = 0.15).

Limitations, reasons for caution: The main limitation of this study is the number of cases included in the study, as we studied one triplet, 3 twins and 4 single pregnancies.

Wider implications of the findings: This might be the first time that AI has been used to analyse the behaviour of embryos resulting in multiple pregnancies. The transfer of a slowly dividing embryo and/or with a large ICM could result in a multiple pregnancy.

Trial registration number: not applicable

[5]*Fertility Medical Group, Clinical department, Sao Paulo, Brazil*

Study question: Are morphokinetic embryo behavior and embryo quality as per Known Implantation Diagnosis Score (KIDScore) assessment related to oocyte dimorphism in intracytoplasmic sperm injection (ICSI) cycles?

Summary answer: Morphokinetic embryo behavior and embryo quality as per KIDScore assessment are positively related with oocyte dimorphisms, which was demonstrated by delayed cell cleavage and blastulation.

What is known already: As a routine procedure in intracytoplasmic sperm injection (ICSI) cycles, denudation of retrieved oocytes allows the determination of maturation status and the assessment of morphological features of the cytoplasm, perivitelline space (PVS) and zona pellucida. Oocytes presenting extra and intracytoplasmic dimorphisms have been correlated to impaired embryo developmental potential and implantation. Time-lapse imaging (TLI) systems allow for the mapping of morphological changes or events with the exact time-point of occurrence. The aim of this study was to investigate the relationship between oocyte dimorphisms an embryo morphokinetic events.

Study design, size, duration: This cohort study, performed in a private university-affiliated IVF center from Mar/2019-Dec/2021, included 156 ICSI cycles and 1158 injected oocytes cultured in a TLI incubator (EmbryoScope^{+}). The presences of intracytoplasmic dimorphisms (granulation clusters, smooth endoplasmic reticulum (SER), dark cytoplasm and vacuoles), and extracytoplasmic dimorphisms (large perivitelline space (PVS), PVS granulation, polar body (PB) fragmentation and abnormal zona pellucida) were recorded, and their potential association with embryo morphokinetic events were investigated considering clustering of data.

Participants/materials, setting, methods: Evaluated kinetic markers were timing to pronuclei appearance (tPNa) and fading (tPNf), to two, three, four, five, six, seven, and eight cells (t2 - t8), to morulation (tM), start of blastulation (tSB) and blastulation (tB). Durations of the second (t3-t2) and third (t5-t3) cell cycles (cc2 and cc3) and timing to complete synchronous divisions s1 (t2-tPNf), s2 (t4-t3), and s3 (t8-t5) were calculated. The KIDScore ranking was recorded. The post hoc power was $>$ 95.0%.

Main results and the role of chance: Morphologically normal oocytes (n = 747) reached tPNa (6.0 ± 0.1h vs. 6.4 ± 0.1h), t3 (36.5 ± 0.3h vs. 37.5 ± 0.2h), t6 (50.9 ± 0.5h vs. 52.1 ± 0.3h), tM (88.3 ± 0.8h vs. 91.6 ± 1.2h), tSB (97.4 ± 0.8h vs. 108.8 ± 3.6h), tB (104.7 ± 0.8h vs. 109.3 ± 0.5h) and cc2 (10.0 ± 0.3h vs 10.7 ± 0.2h) significantly faster than oocytes showing intracytoplasmic dimorphisms (n = 411). Significantly faster t5 (48.4 ± 0.3h vs. 50.5 ± 0.8h), t6 (51.5 ± 0.3h vs. 53.0 ± 0.7h), t7 (54.0 ± 0.3h vs. 57.1 ± 0.8h), t8 (57.9 ± 0.4h vs. 60.5 ± 0.9h), tB (107.9 ± 0.5h vs. 113.2 ± 1.1h) and cc3 (11.6 ± 0.2h vs. 13.5 ± 0.5h) were observed in normal oocytes compared to oocyte showing extracytoplasmic dimorphisms (n = 162). The incidence of extracytoplasmic dimorphisms per cohort was associated with decreased implantation (B: −23.9, CI: −37.8 – −10.1) and odds of pregnancy (OR: 0.360, CI: 0.163 – 0.796). KIDScore ranked significantly different between normal oocytes and those presenting ZP (3.8 ± 0.8 vs. 2.7 ± 0.8) and shape dimorphisms (4.1 ± 0.7 vs. 2.4 ± 1.0), and non-resistant membranes (4.4 ± 0.1 vs. 2.8 ± 0.1).

Limitations, reasons for caution: Despite the use of a nested statistical analysis that accounted for the fact that embryos from the same patient share comparable developmental behavior, this study has limitations, such as the retrospective design and small sample size, though an adequate power has been achieved.

Wider implications of the findings: This study adds to knowledge of oocyte quality role in embryo development. Dimorphic oocytes may have inefficient biological machinery. Significant differences, that could not have been noticed in a conventional incubator, were observed in embryo morphokinetic development when normal and abnormal oocytes were compared.

P-130 Progesterone-primed cycles result in slower embryos without compromising the implantation potential, with the advantage of oral administration and potential cost reduction: A time-lapse imaging study

E. Carrilho[1], D. Braga[2,3], A. Setti[2,3], P. Guilherme[4], A. Iaconelli Junior[1,3], E. Borges Junior[1,3]

[1]*Fertility Medical Group, Clinical department, Sao Paulo, Brazil*

Study question: Could exogenous progestin replace the use of an antagonist of GnRH (GNRH-antagonist) without any effects on embryo morphokinetics and implantation rate in freeze-all cycles?

Summary answer: Exogenous progestin leads to slower embryo development and increased cyclés cancellation rate, with increased implantation rate when compared to cycles using an GnRH-antagonist.

What is known already: Improvements in cryopreservation techniques associated with the expansion of elective-single embryo transfer have steadily increased the use of deferred embryo transfers. This gives the opportunity to break away from the standard sequence of stimulation–retrieval–transfer, and to consider new strategies for pharmacological control of follicle growth. Usual ovarian stimulation regimens use an analog of the GnRH to prevent the LH surge and premature ovulation. Since progesterone is able to block the LH surge question remains on whether exogenous progesterone may replace the use of an GnRH analogue without compromising embryo development, in cycles followed by embryo cryopreservation.

Study design, size, duration: This cohort study, performed in a private university-affiliated IVF center, from Mar/2019 - Mar/2021, included 288 freeze-all ICSI cycles and its 2,768 respective embryos. Patients were age matched, according to the age, into groups depending on the protocol used to prevent the LH surge: Progestin-Primed-Group (n = 144 cycles and 1,360 embryos) and GnRH-Antagonist-Group (n = 144 cycles and 1,408 embryos). Embryos were cultured in a time-lapse imaging incubation system (TLI) and embryo morphokinetics were compared among the groups

Participants/materials, setting, methods: Evaluated kinetic markers were timing to pronuclei appearance (tPNa) and fading (tPNf), to two, three, four, five, six, seven, and eight cells (t2 - t8), to morulation (tM), start of blastulation (tSB) and blastulation (tB). Durations of the second (t3-t2) and third (t5-t3) cell cycles (cc2 and cc3) and timing to complete synchronous divisions s1 (t2-tPNf), s2 (t4-t3), and s3 (t8-t5) were also calculated. The KID-Score ranking, laboratorial and clinical outcomes were also evaluated.

Main results and the role of chance: Mean maternal and paternal ages were 37.0 ± 3.8 and 39.0 ± 6.4 years old. Slower tPNa (6.2 ± 0.2 vs. 7.0 ± 0.2, p = 0.008), t2 (27.2 ± 0.3 vs. 26.2 ± 0.3, p = 0.045), t7 (56.4 ± vs. 54.7 ± 0.5, p = 0.046), tM (89.3 ± 0.8 vs. 87.1 ± 0.6, p = 0.045), tSB (101.5 ± 0.8 vs. 110.8 ± 0.1, p = 0.012), tB (111.0 ± 0.8 vs. 108.5 ± 0.7, p = 0.034), were observed among embryos derived from Progestin-Primed cycles. Similar tPNf, t3, t4, t5, t6, t8, timing to cc2, cc3, s1, s2, and s3 were observed among the groups. No significant differences were noted in the Kid-score D5, number of aspirated follicles, retrieved oocytes, oocyte yield, mature oocytes, and rates of mature oocytes, fertilization, and blastocyst formation. The cyclés cancelation (15.7% vs. 2.0%, p = 0.004) and implantation rates (63.1% ± 6.1 vs. 44.4% ± 6.3, p = 0.004) were increased in the Progestin-Primed-Group, however no significant differences were noted in the cumulative pregnancy (64.4% vs. 49.0%, p = 0.104) and miscarriage rate (2.6% vs. 8.6%, p = 0.554) for Progestin-Primed and GnRH-Antagonist groups, respectively. The expense for the ovulation prevention using the GnRH-Antagonist was U$318.18, while by using progestins U$ 11.05 was sufficient to inhibit the premature LH surge.

Limitations, reasons for caution: This study has limitations, such as the retrospective design and small sample size.

Wider implications of the findings: Despite the increased implantation rate and potential cost reduction, the high cancellation rate and slower embryo development in the progestin-protocol cannot be ignored. Delayed embryo transfer due to the freeze-only approach may also be inconvenient. Before considering any protocols for LH surge prevention, pros and cons must be carefully evaluated.

Study question: Can artificial intelligence (AI) identify which patient and cycle specific variables are most important for predicting blastocyst utilisation rate (BUR) on day 5?

Summary answer: Number of mature oocytes (MII) injected is the most significant variable for predicting BUR. Highest BUR association with MII is found when six MII injected.

What is known already: The day 5 usable blastocyst rate originating from the accumulation of embryos being transferred and cryopreserved is one of the most informative key performance indicators (KPI) in an IVF laboratory. As per the Vienna consensus, the blastocyst development rate competency value is set as $\geq$ 40% with the benchmark value set as $\geq$ 60%. Artificial intelligence (AI) has been integrated into clinical settings as a technological advancement aimed to improve clinical success rates. Identifying the predictors that can result in an increased BUR on day 5 can be an additional tool towards improved cycle outcomes.

Study design, size, duration: In this retrospective, multicentre study, we evaluated six variables for predicting BUR using an artificial neural network (ANN). Study was performed in two fertility centres, between March 2021 and August 2022. A total of 865 cycles were included. Cycle exclusion criteria: Preimplantation genetic testing (PGT), advanced maternal age (AMA) $>$38, infertility aetiology of endometrial origin, severe oligospermia and epididymal/testicular sperm extraction. Primary outcome measure was the BUR on day 5 for the different variables.

Participants/materials, setting, methods: A total of 865 cycles were analysed using the ANN model with six variables: Number of MII oocytes injected (ICSI), use of autologous/donated gametes, maternal age at oocyte pickup (OPU), sperm concentration, progressive sperm motility rate, and fertilisation rate. Cycles were divided into training and test set through stratified random sampling: 73.2% (633) training and 26.8% (232) test. BUR on day 5 was grouped into $<$60% and $\geq$60% as per Vienna consensus benchmark values.

Main results and the role of chance: Number of MII oocytes was found to be the most important variable (100%) followed by the type of gametes used (54.1%), sperm concentration (32.9%), age at OPU (24.7%), progressive sperm rate (23.4%) and fertilisation rate (17.1%).The effect of MII injected on BUR was then investigated and results indicated an inverse correlation, with increasing MII injected resulting in decreased BUR (correlation coefficient of $r=0.344$,$p<0.001$). According to the performed model, 6 injected MII produces the higher rate of utilisation (62.9%).

Performance of ANN model was assessed by positive predicted value (PPV), negative predicted value (NPV), false positive rate (FPR), false negative rate (FNR), overall accuracy (OA), sensitivity and specificity. PPV for the training and test sets was 62.2% (194) for the $<$60% EUR on day 5 group and 79.8% (256) for $\geq$60% EUR on day 5 group and 64.8% (83) for the $<$ 60% EUR on day 5 and 81.7% (85) for $\geq$60% EUR on day 5 group, respectively. OA obtained from training and test sets were 71.1% and 72.4% for the $<$60 and $\geq$60% EUR on day 5 groups, respectively. The area under the curve (AOC) to predict the UR on day 5 group was found to be 77.6%.

Limitations, reasons for caution: The results represent the experience gained from current practice and not of a prospective controlled study. Clinical outcomes using this approach were not explored. Several other patient and cycle variables can also be investigated.

Wider implications of the findings: The number of oocytes retrieved is associated with live birth rate with 15 being the ideal maximum. Increasing oocyte numbers however, can bear greater risks. Predicting embryo utilisation rate on Day 5 can guide the way towards personalised treatment and safety.

P-132 Does the automated blastocyst assessment system, iDAScore®, provide valuable data for predicting the results of preimplantation genetic testing for aneuploidy (PGT-A)?

N. Nakajima[1], H. Kawano[1], A. Takai[1], M. Abe[1], A. Ochi[1], M. Chen[1], M. Shinoda[2], M. Yoshida[2], N. Yamashita[2]

[1]*Yamashita Shonan Yume Clinic, Embryologist, Fujisawa city- Kanagawa, Japan*
[2]*Yamashita Shonan Yume Clinic, Gynaecology, Fujisawa city- Kanagawa, Japan*

Study question: What iDAScore® could indicate the presence of euploidy in PGT-A? Is it a valid predictor of the result of PGT-A?

Summary answer: PGT-A results with an iDAScore® of 8.3 or higher can indicate euploidy. However, patient age and trophectoderm (TE) grade can be effective predictors as well.

What is known already: PGT-A was approved as a general test in Japan in 2022. Currently, only patients who meet the criteria of Japan Society of Obstetrics and Gynecology can undergo the test. It is expected that the test will improve the live birth rate and reduce the miscarriage rate. The iDAScore® uses artificial intelligence and deep learning to score blastocysts. It is anticipated to be more objective than is morphological evaluation, which varies among individuals. Unlike PGT-A, the iDAScore® can assess embryos without cellular invasion. However, only a few reports have investigated the association between PGT-A and iDAScore® results.

Study design, size, duration: The study was performed retrospectively on 3,781 cycles of *in vitro* fertilization (IVF) conducted at our clinic between August 2020 and October 2022. Of the total of 5,684 embryos derived from conventional IVF or intracytoplasmic sperm injection that were cultured in a time lapse incubator, 293 blastocysts were used in the study.

Participants/materials, setting, methods: On the basis of their PGT-A results, the blastocysts were divided into euploidy and aneuploidy groups. The mean age of patients in each group, the methods of insemination, and the median iDAScore® were evaluated. The area under the curve (AUC) and the cut-off value were calculated from the PGT-A and iDAScore® results. A logistic regression analysis of the predictive parameters of PGT-A results, including the iDAScore®, was also performed.

Main results and the role of chance: Patients' mean ages in the euploidy and aneuploidy groups were 38.5 and 41.5 years, respectively. This was significantly higher in the aneuploidy group ($P<0.001$). There was no significant difference in the stage of maturity at oocyte retrieval ($P=0.302$). Similarly, no significant differences were associated with method of insemination ($P=0.961$). The median iDAScore® for the euploidy group was 8.7; for the aneuploidy group, it was 7.8. This result was significantly higher in the euploidy group ($P<0.001$). The AUC, calculated from PGT-A results and the iDAScore® with receiver operating characteristic curves, was 0.685 (95% CI [0.617−0.754]). The cut-off value was 8.3. The logistic regression analysis of age, stage of maturity, insemination method, timing of blastocyst freezing, diameter before blastocyst freezing, inner cell mass, TE grade in the Gardner classification, and iDAScore® as parameters for the PGT-A results indicated significant differences for age and TE grade (age: $P<0.001$, odds ratio [95%CI]: 1.320 [1.19-1.45]; TE grade 2: $P=0.03$, odds ratio [95%CI]: 2.480 [1.11-5.57]; TE grade 3: $P=0.02$, odds ratio [95%CI]: 3.740 [1.27-11.00]), while no significant differences were associated with the iDAScore®.

Limitations, reasons for caution: The iDAScore® is likely to depend on the timing of blastocyst freezing. Furthermore, the iDAScore® utilised in this study was the score of blastocysts that fulfilled our freezing criteria; the blastocyst that reaches a size of at least 150-160 μm in diameter on Day 5,6, or 7 is frozen.

Wider implications of the findings: An iDAScore® of 8.3 or above could indicate a euploidy PGT-A result. However, the logistic regression analysis indicated that age and TE grade were more significant predictors than the iDAScore® was. Therefore, it is difficult to predict PGT-A results from the iDAScore® itself.

Trial registration number: Not applicable

P-133 A study of the relationship between in vitro embryo development and maternal hypothyroidism

D. Dorjsuren[1], C. Orgilbold[2], E. Budzaya[1], E. Arigbukh[3], B. Nomundari[3], E. Odkhuu[4], M. Munkhzol[3], O.U. Zesemdorj[3]

[1]*RMC National IVF center, Clinical laboratory, Ulaanbaatar, Mongolia*
[2]*RMC National IVF center, Embryology laboratory, Ulaanbaatar, Mongolia*
[3]*Mongolian National University of Medical Science, Pathophysiology, Ulaanbaatar, Mongolia*
[4]*RMC National IVF center, Clinical Director, Ulaanbaatar, Mongolia*

Study question: Are there an association between the maternal thyroid condition and in vitro fertilization (IVF) outcomes?

Summary answer: Maternal hypothyroidism was found to be related to oocyte maturation and blastocyst development.

What is known already: Previous studies have shown that thyroid-stimulating hormone (TSH) levels affect ovarian stimulation in assisted reproductive technology (ART). In addition, changes in serum TSH levels have been linked to a sub-optimal environment for the implantation and development of the embryo. Thyroid-related receptors are present in granulosa cells, ovaries, and the endometrium. In addition, those receptors play a role in ovulation and folliculogenesis. This study aims to determine the association between maternal hypothyroidism and adverse implications for IVF outcomes in IVF/ICSI treated women.

Study design, size, duration: This retrospective study performed 333 cycles of 208 patients with TSH levels ranging from 0.043-16.627 μIU/mL, treated at the RMC National IVF Center between 2019 and 2022. The study population consisted of 1171 oocytes, which were divided into two groups based on their maternal basal TSH levels: normal TSH $\leq$2.5 μIU/mL (control group, n = 865, euthyroid) and higher TSH $>$2.5 μIU/mL (case group, n = 306, hypothyroid).

Participants/materials, setting, methods: Maternal basal serum TSH levels were measured using Fluorescence Enzyme Immunoassay on the third day of the menstrual cycle. IVF outcome expressed oocyte maturation, fertilization, cleavage, and blastocyst formation rate. Oocytes were divided into mature (metaphase II) and immature (metaphase I and prophase I) groups. Blastocysts are graded by the Kato Ladies Clinic classification system and divided into high potential (A and B grades) and low potential (C, D, and E grades) groups.

Main results and the role of chance: In our study, there was no statistically significant difference in age and partner's semen criteria between the two groups ($p > 0.05$). As regards oocyte maturation, MII oocytes retrieved significantly higher in the control group (82.2% vs. 75.8%). Logistic regression analysis found that TSH levels $>$2.5 μIU/mL were related to statistically significantly increased risks of oocyte maturation stages like MI or GV (Age affect adjusted model: B = 0.456, p = 0.005; OR = 1.578, 95% CI = 1.146-2.175). The fertilization, cleavage, and blast formation rates have no differences between the groups. However, 91% (n = 324/356) of higher potential blastocysts in the control group were significantly higher than the case group (79.7%, n = 106/133). While, by the logistic regression analysis found that higher TSH levels ($>$2.5 μIU/mL) were related to statistically significantly increased risks of lower potential for implantation grades (B = 0.947, p = 0.001; OR = 2.579, 95%CI = 1.477-4.502).

Limitations, reasons for caution: The study relied on TSH as the primary indicator of thyroid function and excluded participants with abnormal prolactin levels. Other markers, such as FT4 and TSHR, should also be considered for a thorough evaluation of thyroid function.

Wider implications of the findings: Thyroid dysfunction can negatively impact IVF success, and screening and managing thyroid function in women undergoing IVF are essential. More research is needed to understand the mechanisms and develop strategies to improve oocyte and blastocyst quality.

[5]*Sahlgrenska University Hospital, Reproductive Medicine, Gothenburg, Sweden*

Study question: Can iDAScore v2.0 predict likelihood of development into a utilizable blastocyst from time-lapse images captured during the first two or three days of embryo development?

Summary answer: iDAScore v2.0 predicts utilizable blastocyst formation from time-lapse images of early embryo development. Specific score thresholds can be established to ensure high specificity of prediction.

What is known already: Treatment efficacy would benefit from a reliable method to predict the potential of early embryos to develop into utilizable blastocysts and select fresh IVF treatment cycles suitable for blastocyst culture. Reports indicate that time-lapse images captured during the first few days of development and analyzed by deep learning methods may be an accurate approach. A fully automated AI model, iDAScore, is reported to be more accurate than routine morphology and morphokinetics for prediction of implantation. However, the applicability of iDAScore calculated on day 2 and 3 as a tool to predict blastocyst development has yet to be tested.

Study design, size, duration: This is a retrospective multicenter cohort study including time-lapse videos of 9111 embryos cultured to blastocyst stage, from 1283 fresh IVF treatments between 2016-2021 at two ART clinics together performing $>$2000 OPU per year. Images captured during the first days of culture were used to calculate iDAScores (at 48 and 66 hours post insemination) and determine the ability to discriminate embryos likely to develop into utilizable blastocysts according to Gardner score of 3BB or more.

Participants/materials, setting, methods: Patients were required to be undergoing IVF treatment using their own (autologous) oocytes whereby all zygotes were cultured up to the blastocyst stage in GTL® culture medium using the Embryoscope+® time-lapse system (Vitrolife, Gothenburg, Sweden). At least two experienced embryologists graded blastocysts on day 5/6, selecting utilizable blastocysts for transfer/vitrification. To evaluate the performance of iDAScore to predict development into utilizable blastocysts, sensitivity, specificity, and area under ROC curve (AUC) values were calculated.

Main results and the role of chance: The blastocyst utilization rate was 43.8% (3990 utilizable blastocysts of 9111 day 2/3 embryos developing from 2PN zygotes). Prediction of utilizable blastocysts obtained AUCs of 0.768 (0.759 - 0.778) and 0.782 (0.773 - 0.791) for day 2 and day 3, respectively. These results suggest IDAScore prediction performed slightly better when calculated on day 3 than on day 2. The ability to discriminate between utilizable and non-utilizable blastocysts at different thresholds of iDAScore on day 2 and on day 3, suggests that embryos should have a minimum iDAscore of 5 on day 2 to obtain a high specificity of 89%, and a threshold of 6 on day 3 to obtain a high specificity of 88%. Lower sensitivities were observed for these potential thresholds, 35% on day 2 and 41% on day 3.

Limitations, reasons for caution: This is a retrospective analysis where most cycles have at least five zygotes that supported subsequent blastocyst development, limiting relevance for patients with fewer zygotes. IDAScore is developed to predict implantation potential, not utilizable blastocyst, thus could be an underestimation of the potential performance of a model for utilization prediction.

Wider implications of the findings: The iDAScore v2.0 may provide valuable information for embryologists and be useful as a prognostic tool to select patients with high chance to obtain blastocysts based on day2/3 time-lapse images and thereby may achieve similar live birth rate per transfer with no need for extended culture.

Study question: Do morphokinetic parameters vary between male and female preimplantation embryos?

Summary answer: We observed no significant differences in morphokinetic characteristics between male and female preimplantation embryos

What is known already: Studies across various mammalian species, including humans, suggest that male and female embryos differ in their gene expression and metabolic phenotypes. These variations may inherently affect the timing and duration of key preimplantation events. In the context of ART, such developmental differences may ultimately bias embryo selection, leading to an unbalanced sex ratio in the resulting offspring. To date, only a few studies have explored the relationship between morphokinetic patterns and human embryo sex. While some suggest subtle sex-specific variations in human embryo growth dynamics, results have been conflicting and currently no clear consensus has been reached.

Study design, size, duration: Retrospective study of morphokinetic data obtained from 175 preimplantation embryos. The study included 175 cycles performed at two IVF centers, between March 2018 and June 2021. Only fresh oocyte donation cycles using intracytoplasmic sperm injection (ICSI) and fresh single embryo transfer (SET) were assessed. Sex of the embryos was obtained from live birth data. Overall, our analysis included 92 female and 83 male embryos.

Participants/materials, setting, methods: All embryos were cultured in a timelapse incubator in standardized conditions. The morphokinetic parameters assessed included: time to pronuclear fading (tPNf), times to 2–5 cells (t2, t3, t4, t5), time to 8 cells (t8), time to start of blastulation (tSB) and time to full blastocyst stage (tB). All parameters were measured in hours post insemination (hpi). A two-tailed Student's *t*-test was used to compare morphokinetics between embryo sexes. A $p<0.05$ was considered statistically significant.

Main results and the role of chance: We observed no significant differences in morphokinetic parameters when comparing cycles resulting in female vs. male live births: tPNf (21.8 ± 3.3 vs. 22.3 ± 3.4 hpi; $p>0.39$); t2 (24.6 ± 2.5 vs. 25.0 ± 2.5 hpi; $p>0.34$); t3 (35.3 ± 3.3 vs. 35.8 ± 3.1 hpi; $p>0.28$); t4 (36.3 ± 3.4 vs. 36.9 ± 3.7 hpi; $p>0.20$); t5 (47.9 ± 4.7 vs. 48.0 ± 4.8 hpi; $p>0.88$); t8 (54.0 ± 6.5 vs. 54.1 ± 6.5 hpi; $p>0.91$); tSB (86.3 ± 14.6 vs 85.7 ± 15.5 hpi; $p>0.78$) and tB (93.0 ± 16.9 vs. 93.2 ± 17.2 hpi; $p>0.94$). These findings suggest that the timing of key developmental events does not vary between male and female ICSI-derived preimplantation embryos.

Limitations, reasons for caution: The main limitation of this study is its retrospective nature and sample size. We analyzed the data of embryos leading to a live birth; therefore, caution is warranted when generalizing results to non-implanting embryos.

Wider implications of the findings: Male and female human embryos display similar morphokinetic patterns throughout preimplantation development in our study. Accordingly, embryo selection in a timelapse setting based on developmental characteristics does not bias sex ratios in resulting live births.

Study question: Does the embryo evaluation model iDAScore v2.0 correlate with manually assessed cell numbers and fragmentation grade in early-stage embryos?

Summary answer: iDAScore v2.0 significantly correlated with morphological assessment of preimplantation embryos on days 2 and 3. Correlation between cell numbers and iDAScore decreased with increasing fragmentation.

What is known already: Time-lapse technology, including continuous documentation of embryo development, has enabled the implementation of more automated scoring systems, based on images and video sequences. iDAScore (ranging from 1-9.9) is a fully automated annotation-free scoring system based on deep learning and has been shown to discriminate between implanting and non-implanting embryos to a similar extent as KIDScore, which required manual annotations. iDAScore v2.0 also demonstrated a good agreement between predicted probabilities and observed implantation rates. However, not much is known regarding the correlation between specific morphological day 2 and day 3 variables and iDAScore v2.0.

Study design, size, duration: Retrospective observational study from two ART centers, together performing >2000 OPU per year. The study includes all normally fertilized embryos (n = 5378) from 1792 treatments between 2016 and 2021 where fresh single embryo transfer was performed on day 2 or day 3 post fertilization.

The association of iDAScore v2.0 with manual assessment of cell numbers and grade of fragmentation on day 2 (treatments = 762, embryos = 2170) and day 3 (treatments = 1030, embryos = 3208) was analysed using video sequences.

Participants/materials, setting, methods: Inclusion criteria were treatment cycles with own (autologous) oocytes and embryo transfer on day 2 or 3. Exclusion criteria were cycles with double embryo transfers or PGT cycles.

Clinical and laboratory processes were performed according to standard procedures. Time-lapse culture and embryo annotations were performed using the Embryoscope+® with GTL® culture medium (Vitrolife, Gothenburg, Sweden). Wilcoxon rank sum test was used to compare iDAScores between groups.

Main results and the role of chance: Day 2: For the number of cells, iDAScore differed between embryos having <= 3 cells compared to >= 4 cells (medians: 2.3 vs. 4.0, $p<0.001$). The median iDAScores for fragmentation grade 0%; <20%; <50%; >50% were 4.7; 3.9; 2.6 and 2.1, respectively. Furthermore, 0% was significantly different from each of the other groups ($p<0.001$). When cell numbers and fragmentation grade were combined, it was seen that having <= 3 cells versus >= 4 was significantly correlated to iDAScore when the fragmentation grade was scored as 0%, but this association decreased as the fragmentation grade increased.

Day 3: A similar pattern was seen for day 3 morphology analyses. It was found that having <= 5 cells vs. >= 6 cells correlated to a significant difference in iDAScore (medians: 2.5 vs. 4.4, $p<0.001$). The median iDAScores for fragmentation grade 0%; <20%; <50%; >50% were 5.6; 3.8; 2.6 and 2.3, respectively. Furthermore, 0% was significantly different from each of the other groups ($p<0.001$). When combining cell numbers and fragmentation grade in the same analysis, the association of cell numbers to iDAScore decreased as fragmentation increased.

Limitations, reasons for caution: The present study is of retrospective design, with analysis of data from two clinics, and the results may not apply in a wider context. In addition, only two morphological variables, cell numbers and fragmentation, were included.

Wider implications of the findings: Our results show that there is a strong correlation between iDAScore v2.0 and the number of cells and the fragmentation grade of the embryo, both for each individual variable and when combined. This indicates that iDAScore v2.0 identifies some of the well-established morphological evaluations for cleavage stage transfers.

Study question: Limited studies have explored the correlation between the pronuclear characteristics, developmental potential, and genetic constitution of mono-pronuclear (1PN) zygotes.

Summary answer: Those 1PN zygotes developed into blastocysts have unique pronuclear characteristics and significantly higher rate of diploidy euploidy in comparison with the arrested embryos.

What is known already: It has been reported that 1PN blastocysts have similar morphokinetic features to two-pronuclear (2PN) embryos. Cytogenetic analyses reveal that some of the 1PN embryos have a normal chromosomal constitution.

Study design, size, duration: This retrospective cohort study included the 1PN zygotes from December 2021 to September 2022 (n = 388).

Participants/materials, setting, methods: Patients who underwent IVF or intracytoplasmic sperm injection (ICSI) in the Women and Children's Hospital of Chongqing Medical University were recruited. Only 1PN zygotes cultured in the time-lapse incubators from the oocyte retrieval day were included. The pronuclear characteristics, including the area and diameter of the pronuclear, the number of nuclei, and the distance between the pronuclear and the near-polar body (DPNP), and the genetic constitutions were investigated.
